BILBEE HA WITTA DA

JOHN McHUTCHEON.

Aug. 6, 1887]

The GARDEN

AN
ILLUSTRATED WEEKLY JOURNAL

OF
HORTICULTURE IN ALL ITS BRANCHES.

FOUNDED BY

W. Robinson, Author of "The Wood Garden," "English Flower Garden," &c.

" You see, sweet maid, we marry
A gentler scion to the wildest stock;
And make conceive a bark of baser kind
By bond of nobler race: This is an art
Which does mend nature, — change it rather, but
The art itself is nature."

Shakspeare

VOL. XXXI. MIDSUMMER, 1887.

LONDON:

OFFICE: 37, SOUTHAMPTON STREET, COVENT GARDEN, W.C.

[Aug. 6, 1887.

TO THE MEMORY OF

JOHN McHUTCHEON

(*GARDEN* 1871—1887)

THE THIRTY-FIRST VOLUME OF "THE GARDEN"

IS DEDICATED.

W. R., July, 1887.

Agathaea celestis, 486
Akebia quinata, 529
Alaternus, the, 59
Albany, West Australia, 4
Album, a Fern, 179
Alber, the American Wych, 544
Algerian Silver Fir, the, 174
Allanudas, 38, 469
Allium grandiflorum, 486; *Hermetti grandiflorum*, 486; *neapolitanum*, 344; the *Neapolitan*, 318; *giganteum*, 574, 596
Allisorus crispus, 179
Aloe plicatilis, 419
Alonsoa incisa, 372
Aloysia citrodora, 499
Alpinia pumila, 185
Alpine Auriculas, shaded *v.* unshaded, 278
Alpine Wallflower, 534
Alseusmia macrophylla, 226

Alsophila Rebeccae, 228
Alstromerias, 394
Alum Root, the smooth, 596
Amaraloya princeps, 294
Anaryllids at Holloway, 312; crossing, 279
Americum, note on, 299
Anaryllis, 98, 235, 315, 471, 541; *Audient*, 495; Dr. Masters, 312; *formosissima*, 215, 226, 574; hybrid, 259; *marginalis* *conspicua*, 119
America, Rose growing in, 297
American Blackberries, 500
Azalea nobilis, 294, 278
Angelopsis Veitchii, 335
Amygdalus nana, 379
Andromeda japonica, 218, 219, 419; *boottiana*, 612
Anemia, 258
Anemone coronaria, 467, 481; double scaplet, 434; *Famina*, a ramble after, 295; *memorosa*, 393; *Robinsoniana*, 495; *stylvestris*, 503; the *Apenitue*, 588; the *Crown*, 549; the *Pan*, 429; the *Sawdrop*, 593; *trifolia*, 446
Anemones, French, 145; Irish, 383; Japan, 33; spring-flowering, 188; "St. Bridget", 388
Angraecum bilobum *Kirkii*, 29; *elatum*, 359; *Kotschyi*, 323; *sesquipedale*, 122, 272
Angrepanus, 323
Annual, what is an, 511
Annuals, half hardy, 203
Arachthia sarcocolla, 49
Arceuthis glauca, 327
Aschua a *reana*, 29
Anthurium Andreanum, 299; *Andreanum* *El-pl.*, 372; *Scherzerianum fasciatum*, 301; *ferriense*, 602
Anthurium, 493; at Burford Lodge, 229
Antirrhinum assurgens, 581
Antirrhinum, *erimison*, 511
Ants, destroying, 134; in viney, 557; in vineries, to destroy, 606
Aotus gracillima, 372, 460, 513
Aphelandra a nautica, 211
Aphelandras, 211
Apocynon distichydon, 609
Apple, a good keeping, 478; *Blenheim Orange*, 35, 74; blossom, 595, 607; *Blue Pearmain*, 106; *Duck's-bill*, 99, 143; *Lane's Prince Albert*, 193; *Lord Derby*, 2; *Norfolk Bantlin*, 493; *Pomeroy*, 274; *Prince Bismarck*, 196; *Sturmer Pippin*, 196; the *Chinese*, 527; the *Sandringham*, 147; the *yellow transparent*, 597; green *Orstand*, 606
Apple-tree flower buds, 147
Apple trees, ornamental, 597

Apples, 55, 348, 499; American, 284; as ornament d trees, 499; dessert, 399; *English c.* American, 166, 252; for small orchards, 147; good, 365; home-grown *v.* American, 192; identifying varieties, 436; keeping, 194; late-keeping, 317, 364, 491, 539, 556; market of the future, 234; on *Paradise* stock, 73; ornament d, 421, 479; store rooms for, 192; two good, 349; well kept, 437; with handsome flowers, 438; thinning, 577
Apricot as a *corbin*, 508
Apricot blooms, 501
Apricot tree, a curious, 391
Apricots, 56, 69
Apulegias, 572
Aralias, 512
Araucaria excelsa, 279; *imbricata*, 354
Araucaria uncinata, 37; un-ightly, 13
Arbo-vite, the *G-bleu*, 311; the *gray*, 615
Arbutus, the *Oak-leaved*, 259; the *tall*, 499
Arbutus aspera arbuscula, 251; *undulata*, 318
Artemisias, 312
Aristolochia elegans, 142
Armeria cephalotes alba, 596; *granuliflora*, 395; *Lan heana*, 581
Arnebia echinoides, 486, 534; *Gilbithi*, 534
Arolla, the, 104
Arthropodium cirrhatum, 441
Artichokes, *Globe*, 163, 286; *Globe*, and the *frust*, 171; *Jerusalem*, 151
Arum Lilies, growing, 267; at *Kew*, 117
Asch, the *Mount*, 359; the *Mountain*, at home, 265; varieties of, 392; the *Weeping*, 13
Asparagus, 78, 151, 426, 490; culture profitable, 19; forcing in beds, 39; forcing, 103, 152; notes, 543; planting, 353; *plumosus*, 341; *plumosus nans*, 188, 143, 237, 488; spring treatment of, 374
Asphalte walks, 541
Aspidium, 325
Asplenium longissimum, 382; *Adiantum-nigrum*, 586; *germanoicum*, 587; *fontanum*, 78; *im-colatum*, 587
Asplenium for baskets, 382
Aster spectabilis, 6, 31; *alpinus rubra*, 598; *Stracheyi*, 574
Asters, sowing, 335; in spring, 142
Ataeca cristata, 561
Aubrietias, 446, 496
Aucubas, 482, 552
Auricula, garden, 147; origin of the edged, 484; rules, the, 417; spring notes on, 411
Auriculas, 82, 369, 433, 462, 503; alpine, 446; alpine, shaded *v.* unshaded, 278; border, 466; fancy, 467; *laced*, 468, 485, 535, 561; seedling, 229; single white, 486

Auricula and Primula Society, the National, 294, 405
Asiatic Botanic Garden, 343
Austrian Pine, 579
Autumn Daffodils, 582
Azalea Deutsche Perle, 164, 213; *Miss Jarrett*, 488; *Mrs. Carmichael*, 279; *mollis*, 38, 312, 328, 488; *rosea*, 304, 328; the *Californian*, 611
Azaleas, 47, 443, 512; after blooming, 395; American double, 499; and insect pests, 192; Indian, from Cornwall, 403; planted cut, 11; soil for, 452; root for, 412; hardy, in bloom, 611

B.

Balearie Sandwort, 600
Bambus, hardy, 18
Bambusa Castelloni, 128; *Metake*, 238, 288
Bananas, 328
Banksian Roses, 527
Barberries, the best evergreen, 311
Barberry, Darwin's, 13, 83; the *Golden*, 543; the *Nepaul*, 91; the purple, 521, 611
Bark, allowances for, 63; and bark strip-ting, 335
Barkaria Vanneriana, 61
Barrenworts, hybrid, 527
Basic slag, 439, 454
Baskets, market, 377
Bauera rubrioides, 394
Beam Tree, the white, 129
Bean, Beck's Dwarf Green, 459
Beans, Broad, 193, 333; dwarf *Ne Plus Ultra*, 333; early green *Longpod*, 78; French, 373, 674; kidney, forcing, 102; runners and French, 391, 472
Beauveria Sanchi, 578
Beaufortia splendens, 466
Beaumontia grandiflora, 271; *undulata*, 441
Bedding cut, 416
Beech, the, 524; the *Cut-leaved*, 173; the *Copper*, 52; the *Copper*, in *Hampshire*, 15; the *Purple*, 34; the *wool*, of, 18
Bees, plants for, 370
Beetles, 61
Beet, 333; *Covent Garden*, 150; *Doll's Crimson*, 399; wintering, 149
Begonia Gloire de Secaux, 164, 294; longevity of the, 300; *Princess Beatrice*, 279; *secotiana*, 38

Sprout, Gilbert's Jubilee, 196
 Sprouts, Brussels, 390, 426
 Spruce, a new variety of, 499; *the Douglas*, 288; Douglas, fragrance of, 556; the Japan Hemlock, 129; Weeping Hemlock, 474
 Staphylea colchica, 183, 226
 Star of Bethlehem, satiny, 409
 Statice Suwarowi, 118
 Statics and their culture, 144
 Stauntonia latifolia, 129, 336, 395
 Steam heating in America, 357
 Stenosemia aurita, 326
 Stephanotis, 178; floribunda, 560; floribunda falling, 201, 202; in stove, 144
 Sterubergia angustifolia, 583; *retucosis*, 583; *Clusiana*, 583; *colchiciflora*, 582; *Fischeriana*, 583; *lutea*, 582, 583; *macrantha*, 583
 Stock, influence of, on scion, 115
 Stockholm, a note from, 394
 Stocks, effect of the winter on, 229; sowing, 585; Brompton and others, 578
 Stonecrop in baskets, 486
 Storax, the large-leaved, 544
 Stove climber, a beautiful, 529
 Strawberries, 9, 471, 493, 539, 557, 608; forcing, 39; hardness of young, 363, 492; in beds, 539; in pots, 192; in pots, watering, 210; shading, 606; the best time to plant, 491; the earliest, 349; planting, 398; preparing for forcing, 192
 Strawberry, the, 675; hardiness of, 347; beds, 576; Black Prince, 605; Blüte, 66; plants, grub on, 430; plants as biennials, 576; La Grasse Sureau, 479; tree, the tall, 499; plants in spring, 423
 Streatham, Orchids flowering at, 307

THE GARDEN.

VOL. XXXI.

FRUIT GARDEN.

SMALL FRUIT GARDENS.

I HAVE often wondered that small gardens attached to villa residences are not oftener than they are laid out as fruit gardens. In many cases they are not large, the soil is often poor in quality; but all things considered, the evidence, as a rule, is in favour of planting fruit trees. People who have passed middle age generally take to fruit culture more than to flowers. Most growers know that vigorous shoots if allowed to develop to their full extent are not fruitful, and such shoots monopolise more than their fair share of the elaborated sap, causing the weaker shoots to grow more weakly than they otherwise would do. How to treat these vigorous shoots is a question that is not always answered in the right way. I propose to answer that question and some others, but before doing so, I will state how such gardens as those to which I have alluded ought to be planted. An amateur, whom I knew some fifteen years ago, acted as to planting and pruning on my advice, and did most of the work himself; and no wealthy landowner, whose garden is filled with the choicest flowers and fruits, could have more pleasure from it than the garden in question yields, though only a narrow strip divided from the neighbouring gardens by low walls on each side. One wall faced the south-west, and this was planted with Peaches, Nectarines, and Apricots, and Black Hamburg and Royal Muscadine Grapes. The wall at the end of the garden did not get much sun, and there we planted a Morello Cherry. On the other wall, which was not much exposed to the sun, we planted Plum and Apple trees. The border in front of the walls was not wide enough, or we would have had a row of cordon Apple trees about a foot from the ground instead of box edging; a few flowers were planted on the borders. The path all round was not a wide one—not much more than 2 feet. If space could have been afforded, the border and path ought to have been 4 feet wide each. The centre of the garden we planted with pyramid Apple and Pear trees, Gooseberries, a few Currant trees, and Strawberries. There was room for three rows of fruit trees worked on dwarf stocks at 6 feet apart. The trees being small at first, two rows of Strawberry plants were placed between them. The Gooseberries stood 3 feet apart; 4 feet would have been better, but we had not much room. The ground

received but little preparation beyond digging it up and adding decayed manure; some decayed fibre from an old heap of Couch Grass was also placed round the roots of each tree when planted. It may be well to observe that I never plant a fruit tree without placing some decayed turfy loam around its roots. Any mangled roots are cut off clean: the hole for the tree is made large enough to permit the fibrous roots to be spread out to their full extent. Under the roots we spread a layer of this fibrous turf, and placed some more of it over and amongst them. This fibrous material is conducive to the formation of quite a mass of roots during the first year, and their formation is accelerated by placing a mulching of decayed manure over the surface of the ground as far as the roots extend. No manure is added to the turfy loam. Wall trees and standards are treated alike. We are not so particular with Gooseberry and Currant bushes, although the same care bestowed upon them would not be labour wasted.

It is desirable to obtain good trees to begin with; they should be purchased early in the season and be sent home in November, or not later than December, and all the arrangements for planting them should be complete before they arrive. Get them into the ground as soon as possible. Some years ago I recommended a fruit grower to purchase some good wall trees, which he did, paying a high price for them. They were planted; but some years afterwards I heard they were doing badly, and on calling I found a large portion of the wood dead. The cause of this was soon discovered. It arose from burying carrion in contact with the roots, and thus killing them; growth was arrested, and they never recovered, even after the carrion was removed. Another grower whom I knew planted some wall trees; he spread out the roots and nailed the branches to the wall, but at the end of four years they had produced nothing but leaves; they made very strong growths annually, which were left to the autumn and then cut out. This being done yearly, the shoots got stronger still, and the trees grew at an alarming rate. The mistake in this case was allowing vigorous growths to develop at all. They ought to have been pinched back in the summer time; shoots not required should also have been cut out at that time. Careful hand-pinching and pruning in summer will restrain tree growth, unless the ground is immoderately rich with manure. Fruit trees do not require

heavy manuring. Ordinary kitchen garden soil that has been annually manured for vegetables would not require any more stimulus of that kind if fruit trees were to be planted. I have the greatest faith in surface dressings with manure, especially during summer: they retain moisture around the roots and near the surface, and induce the roots to work in that direction instead of deep into the ground to find moisture in dry weather. I had recently to lift some pyramid Plum trees which had been planted three years on over-rich ground, and although sufficiently summer pinched to restrain such free-fruited varieties as Victoria, Pond's Seedling, Orleans, Diamond, and others from making too much growth, we found those that did not carry good crops made too strong wood. They were removed from the ground entirely—an operation which has induced them to bear freely. When a tree has been lifted and re-planted, or even root-pruned, the branches should not be interfered with. The object of cutting the roots is to check the supply of food, but if some of the branches are removed the balance between root and top is again restored, and no good results from the operation. A wall tree has a tendency to grow with greatest vigour in the centre, and with least at the base. The balance of vitality can therefore only be well maintained by summer stopping and pruning. If the vigorous centre growths are stopped, those lower down on the wall, which may not require stopping, will grow with greater vigour. Many lay in too much young wood, which is a mistake. No more ought to be nailed in to the wall than will be required for next season. We do scarcely any winter pruning, either in the case of wall trees or in that of trees trained as bushes and pyramids in the open ground.

Insect pests are a great trouble in some seasons Plum trees especially being seldom free from them. Dusting with tobacco powder or washing with a solution of soapy water strengthened with tobacco liquor will destroy them. Red spider often injures Peach and Nectarine trees; it can, however, be destroyed or kept under by frequent syringings in hot, dry weather. Mildew, which may also appear, yields most readily to flowers of sulphur dusted upon the affected parts. The best results in the way of fruit growing cannot be obtained unless the trees are kept clean, and when they show signs of distress in hot, dry weather, mulchings and a good soaking of water benefit

them greatly. In many gardens water is laid on, and can be applied with a hose when wanted. This lessens labour immensely. J. DOUGLAS.

FIGS ON THE SOUTH COAST.

FIGS grow with great luxuriance on the south coast, and ripen fine crops of fruit, but, nevertheless, no attempt is made to turn these advantages to practical account on anything like a large scale for the supply of our markets, although I have not the slightest doubt that anyone growing them with anything like the care that is bestowed on many other fruits would be well rewarded. It is no uncommon thing to find very large Fig trees on this part of the coast that have evidently at some remote period enjoyed the advantage of wall culture, but that have long since left the walls and grown out into wide-spreading heads that produce annually many hundreds of fine fruits each. In autumn such trees must yield a good revenue to their owners, as they invariably sell well, even when other fruits are a glut in the market. I should say that a century back the Fig was far more largely planted than it is now. Very fine specimens may be seen growing on the walls of Salisbury Cathedral; at Eaglehurst Castle, too, overlooking the Solent, some of the largest and most prolific open-air Fig trees in the country may be seen, the main stems being larger than a man's body. Such trees must certainly have left the walls more than a century ago, as the limbs which run out cover a very large space, not only over a wide border and walk, but are stretching out on to the vegetable quarter beyond. They are supported on stout posts, furnished with cross-bearers, and the crops of fine Figs thus produced are enormous. We have in this neighbourhood Figs in all directions growing nearly wild, especially on the old walls of farm and manor houses, where they were evidently carefully cultivated before the advent of cheap glass caused these open-air wall trees to be so much neglected. Now, when so many are inquiring what they can grow for market, it is singular that the Fig is overlooked, for, unlike the open-air Grape, it fruits freely, and ripens its crops in this district even away from walls, and now that Grapes realise such a low price, even from under glass during autumn, I feel sure that the Fig would be more profitable. The Brown Turkey and White Marseilles appear to be the only sorts planted so long ago as these old specimens date back to, and very useful kinds they are. Some of the newer sorts might, however, be tried with good results, for if so much earlier and more prolific in a young state in pots under glass than old sorts, why would they not be equally suitable for open-wall culture? About here very few owners of gardens think it necessary to train Figs close to the walls; they simply plant them in some sunny corner and let them take their chance, and very fine fruits in this way they get. It is rare that the wood of the Fig tree suffers from frost on the coast, and covering up in winter is unknown; if the tips get injured they break out all over from the older wood, and soon recover, but, of course, when this occurs the crop for the current year suffers, as it is only the first show of fruit that can ripen in our short summers. If any regular system of market culture were attempted, it would probably be found the best course to either adopt some of the old devices of our forefathers, or else the modern system of glass copings; at present, although the Fig is so well grown in private gardens, it is almost totally ignored as a market fruit, although it is equal in value to many fruits on which great care is expended. J. GROOM.

Gosport.

Lord Derby Apple.—This is a culinary Apple of great merit. The tree is a robust grower and free fruiter. It is not unlike Lord Suffield in this respect, and at first, when the fruits are small, they might be taken for fruits of that variety, but before harvesting time they become much larger and flatter than those of Lord Suffield. We

have tried repeatedly to keep fruits of Lord Suffield until the new year, but they always shrank very much or decayed; whereas those of Lord Derby are just now in prime condition, and will keep so for three or four weeks to come. It is a noble Apple, of a thoroughly useful description.—J. MITR, *Margam, Port Talbot.*

PEAR CULTURE AT GUNNERSBURY PARK.

THERE is now at Gunnersbury Park one of the best collections of Pears probably to be found in Middlesex. Mr. Roberts has during the past few years planted weeping cordons, covering every piece of available wall with them, and they have now reached a good bearing condition, enabling some definite conclusion to be arrived at as to their quality as bearers. The trees are planted from 2½ feet to 3 feet apart, and they vary in height according to the walls—from 6 feet and 7 feet to 9 feet and 10 feet. Those on a north-west aspect are planted at the back of the plant houses and vineries. Williams' Bon Chrétien gave no fruit on the wall, but shoots trained round a corner, so as to have a south-west aspect, bore fruit. Neither Winter Nelis nor Duchesse d'Angoulême have done well, though the last-named bears well as a pyramid. On this aspect Vicar of Winkfield does remarkably well, while Beurré Superfin fruits but sparingly. Baron de Melo, Souvenir du Congrès, and Marie Louise bear well; while neither Glou Moreceau nor Doyenné du Comice yield anything like satisfactory crops. Van Mons Léon Leclerc does well, also British Queen, but Fondante d'Automne not so well. On the west side of one of the houses Chaumontel bears well, but not a fruit comes on the more northern exposure. On the latter Hacon's Incomparable does very well. Glou Moreceau does remarkably well at Gunnersbury on an espalier. It may be remarked that the borders are all made 2 feet in depth, with a good deal of clay in them.

On a south-west wall, which is fully exposed to the north-east at the back, Mr. Roberts has had good crops of excellent fruit. Pitmaston Duchess is especially fine. Van Mons Léon Leclerc does well anywhere about the garden; but Fondante d'Automne, though doing better than on a north-west wall, is by no means free; Bon Chrétien is here very fine; Eye-wood, an excellent October Pear, bears well; while Beurré Superfin fails here, as it does on the colder aspect, and it does not bear well even under the most favourable circumstances. British Queen, Forelle, and Beurré Bachelier are all very fine; Nouvelle Fulvie bears well and is of excellent quality; Louise Bonne of Jersey is very good; Gansel's Bergamot grows very strong and requires double grafting to make it fruitful; Doyenné du Comice did not yield any fruit; Beurré Clairgeau is very showy and fine, but lacks quality; and Uruaiste on a north-east exposure grows freely, but does not bear any fruit.

Against a north-east wall 10 feet in height Mr. Roberts has planted a large collection. Marie Louise d'Uccle, a portion of the tree on a south-east aspect also, always bears well, and Mr. Roberts strongly recommends this as a market variety, as it is certain to bear a good crop. Doyenné du Comice does not bear so well as on a south aspect. Beurré Bosc is one of the best and freest of Pears; on the other hand, Gansel's Bergamot next to it bore a poor crop. Conseiller de la Cour bears fairly well; Nouvelle Fulvie does very well; Glou Moreceau does best on an east aspect; General Tottleben does not crop freely, nor does Duchesse d'Angoulême; while Pitmaston Duchess is very good indeed; Beurré Diel failed to bear, but British Queen gave a good crop; Thompson's does not bear so well as on pyramids in the open ground; Winter Nelis crops fairly well; Van Mons Léon Leclerc is good; Urbaniste has no crop; Beurré d'Anjou, a few; Prince Consort does well on this aspect; Beurré Hardy is a tardy cropper; Crasane bears well; Easter Beurré does not do well; Zephirin Gregoire is a capital bearer; Beurré Superfin had only a few; Beurré d'Arenberg had very fine fruit; Baron de Melo bore well; Beurré Bachelier had very fine fruit; Josephine de Malines does not even flower on this aspect; Doyenné d'Alençon does not produce fine fruit; Vicar of Winkfield does fairly well; Comte de Lamy is a charming little Pear here; Fondante d'Automne also bears good fruit.

There is an excellent collection of Pears as pyramids. Chaumontel bears moderately, but does not ripen well, and evidently should be on a south wall; Van Mons bears well, and is one of the best; Easter Beurré bears freely; Glou Moreceau, very free bearer; Napoleon, very fine; Morel, very late, a spring Hesse, which it greatly resembles when fully ripe, and is a very heavy bearer; Louise Bonne of Jersey does well as a pyramid; Catillac bears well and the fruits acquire a very fine colour; Thompson's does well; Seckel does moderately well; Fondante d'Automne bears uncommonly well; Jersey Gratioli well; Marie Louise is very good; Bon Chrétien furnishes a very good crop, some of the fruit being particularly fine; Beurré de l'Assomption, good quality, quite equal to Williams, nearly as large in size and earlier; Nouvelle Fulvie is a large bearer; Pitmaston Duchess does well as a pyramid and is fine in flavour; Beurré de Capiamont always bears well; Beurré Rance, a large crop, always bears well; Winter Nelis the same.

It may be remarked that the trees against walls have been planted six years; they are all on the Pear stock, and nearly all of them were root-pruned two years ago. The pyramid trees are some of them of large size, having been planted a good many years ago; while some have been planted only during the past two or three years. R. D.

VINERY BORDERS.

WITHOUT a well-prepared border for the roots of Vines no one can expect to have uninterrupted success in Grape culture. Next to a good border comes a suitable house, and for all practical purposes the lean-to form is the best, affording, as it does, a good long rafter. In order to secure the latter, a high back wall and a rather wide house are essential, conditions under which the best Grapes are produced. Good Grapes, I know, may be grown for a few years where both roots and branches are restricted, but I am alluding to Vines that may be expected to remain in a thoroughly satisfactory condition from twenty-five to thirty years.

With respect to the border, a very important point should be remembered, and that is that the depth must be in proportion to the width. If the width is only 10 feet the depth should be 3 feet, or, in other words, a narrow border should be deeper than a wide one. I prefer one 30 feet in width and 18 inches in depth to a narrower and deeper one, but if I could only secure a space 20 feet in width, I should make the depth 2 feet. In estimating the space I, of course, include the inside border, and I am decidedly in favour of planting inside, whether there is an outside border or not. Borders should never, however, be constructed altogether inside, unless there is every prospect of the roots getting all the moisture that they require. Inside borders need large quantities of water to sustain the Vines in a satisfactory condition for a number of years. Therefore, in all doubtful cases, it is best to have both an inside and outside border, and the front wall should be set on arches, so that by planting close to the wall inside the roots may go outside, where they will be independent of the cultivator as regards moisture. I am in favour of a rather large root-run, and then one need not be afraid to depend entirely upon a good loamy soil, and a fair proportion of brick-rubble to secure healthy growth and full crops of good fruit.

Charcoal is not of much use in borders, and I am not prepared to advocate a large outlay in bones or other ingredients of a like character. I do not say that I would not use a limited quantity of half-inch bones if they were to be had, but I prefer to place my faith in good loam, when it can be had in sufficient quantity and fibrous in character. I mix one cartload of brick and lime rubble with four times that amount of loam, and I have no reason to complain of the sustaining property of this mixture. Twenty years' experience has fully convinced me that loam taken from the blue lias formation is unsuitable for Vines; that taken from the red sandstone is best. The latter not only sustains the plants for a longer time in vigorous health, but their growth from the first is more satisfactory. A sufficient quantity

of some opening material should always be used along with the loam to keep it from getting into a close, sour condition. I do not, however, agree with using too much rubble, but a limited quantity is essential for keeping the soil in a healthy state. Vine roots do not object to come in contact with half a brick or a lump of old mortar; this is evident from the fact that the greatest amount of roots is found near such materials. Manure in Vine borders is unnecessary where a loam of a substantial character can be had; in fact it often does more harm than good, inasmuch as it encourages growth that is too strong to become hard or solid, and if used at all freely it sours the soil and renders it unfit for the roots. If the loam should be considered deficient in strength, a good layer of half rotten manure laid on the surface as soon as the border is completed will afford the roots all the nourishment they want in order to give them a good start, and the fertility of the soil may be kept up by repeating the application every winter. If turfy loam is used (and it is best), 6 inches must be allowed for sinking, and not less than 4 inches for other descriptions of soil.

As to draining borders, I maintain that Vines are more likely to suffer from draining too much than too little. Unless the position is very low and damp it ought not to be drained at all, and then only sufficiently to carry away any water that may soak into it from the surrounding ground. There are very few districts in England where the rainfall is in excess of the requirements of Vines; therefore to facilitate its departure from their roots is to rob them of their needful supply of moisture. Inside Vine borders should never be drained unless under very exceptional circumstances. Where it is thought desirable to lay down a drain for outside borders, one along the front will in most cases be sufficient, and that must have a proper outlet or it will do more harm than good. As regards the bottom of the border, what requires to be done to it must depend entirely upon circumstances. Where the subsoil is bad and within 2 feet of the surface it is desirable to put a layer of concrete over it to prevent the roots from penetrating it, but in the majority of cases it will be better to depend upon lifting the roots once in every eight or ten years, so as to be sure of their being kept out of the bad soil. This is not a serious undertaking; if half the Vines are lifted at one time, the loss in the crop will not be great.

The best black Grapes for early forcing are the Black Hamburg, and the best variety of this sort is the Frankenthal. There can be no mistaking this fine Grape when one has once seen it, for it produces large and evenly-shouldered bunches, and the skin of the berries has a hammered appearance. The Mill Hill Hamburg is a more hardy variety, but its bunches are usually short and too heavily shouldered to be handsome. The best white sort for early forcing is Foster's Seedling. It is a good-bearing and free-setting Grape, but it should only be planted in the proportion of one to three of the Hamburgs. For cool vineries the Black Hamburg and Buckland Sweetwater are the best. The last-mentioned is a fine Grape, but it requires to have a portion of its roots in an inside border. For an intermediate vinery the Madresfield Court Muscat is a valuable Grape when one can master its cracking propensity, which is rather difficult to do; otherwise it has a noble appearance, and is a delicately flavoured Grape. Alicante is an accommodating sort, and is, I think, the easiest of all Grapes to manage. It produces huge bunches of a jet-black colour, but in flavour it is only third-rate. The Muscat of Alexandria is the best flavoured of all white Grapes, and it is a fairly good keeper. The two best flavoured and best keeping black sorts are Lady Downes Seedling and Mrs. Pincee Muscat. The last is but little inferior in flavour to the Muscat of Alexandria. J. C. C.

Market Pears.—"R. D." tells readers of THE GARDEN that Beurré de Capiaumont is a dessert Pear of good quality. If he had said it was a good paying variety, he would have

spoken the truth. Further he adds that Beurré Diez is a dessert Pear of the highest quality, which it is not. I have sold both in Covent Garden Market, and grown both, and my opinion is that they are not even second class.—A PEAR GROWER.

OUTDOOR GRAPES.

THE danger incidental to any effort to popularise the cultivation of outdoor Grapes is, that some may be induced to regard it as a sound trade. That would indeed be a grave error. Compared with good, cool vinery Grapes at 1s. per lb., or of good imported Grapes at 4d. and 6d. per lb., the best home-grown outdoor Grapes would not fetch more than 2d. per lb., and even then only after good cultivation combined with thinning the berries, and the best crop that could be produced at 2d. per lb. could not pay for such expense and trouble. Those who know what the prices paid to growers will probably think that the grower of such outdoor Grapes would be fortunate if he obtained 1d. per lb., especially if 2d. per lb. is the retail price. If we compare the produce of any given south aspect house, wall, or wood fence—indispensable associations for the production of fairly ripe Grapes outdoors—with what a similar area will yield in Apricots, Pears, or even Tomatoes, and all these products first-rate in quality and saleable, we shall find that the latter far excel in value that of Grapes of any kind, and at the same time they are more reliable as croppers. If it be pleaded that outdoor Grapes may be profitably utilised in the making of British wines—and that may be so—it is evident at once that not only is the knowledge of wine-making domestically almost extinct amongst us, but also that even the best can hardly hope to compete with the cheap products of the Continent. Home-made wines are at the best acidulated sharpness, neutralised by ample quantities of foreign sugar, combined with the illusive sparkling of carbonic acid gas. Probably much foreign wine is no better, but it is hardly worth while to encourage such a domestic industry. Outdoor Vines may be grown with us for two reasons: first, to see how near it may be possible to induce certain kinds under highly favoured conditions to approach fruit-quality found in vineries; and secondly, as house, wall, or fence coverers. Vines have the advantage that they can run up and cover elevations not accessible to other fruit trees. Garden walls also have a very pleasing look where Vines run up the piers and along the tops of the intervening spaces, forming pretty frames in which are set Peaches, Apricots, Pears, or Tomatoes, or perhaps Camellias or Roses. These are purely forms of incidental cultivation. Without doubt, black Grapes are the most pleasing for such purposes, as the coloured bunches of fruit, even though not really ripe, are more pleasing to the eye in connection with the green foliage than white Grapes. Of course, we have no black kinds which ripen so thoroughly in the open as the White Sweetwater and Royal Muscadine do, excepting, perhaps, the little Black Cluster or the Parsley-leaved variety; but I have found Black Alicante, Hamburg, and Royal Ascot to colour admirably outdoors, the former fruiting with great freedom. Fruit of this kind, even though well coloured, is so excessively sharp, that it can in no sense be termed palatable, although perhaps equal to many of the Canadian Grapes. A. D.

"Veronica" and outdoor Grapes.—There has been a good deal said about Grapes in THE GARDEN of late. Those who say good Grapes may be grown in the open air in England would help their arguments greatly by telling one where good fruit may be seen. Those Leicester Grapes were probably encountered by "Veronica" at that period of vigorous sense when the crunch of a green Gooseberry is a welcome sound! If "Veronica" goes back to the reasons for calling Lee's nursery the "Royal Vineyard," he may prove much, but not throw light on Grape-growing on open walls in our own day. Really eatable Grapes should be grown in more than one favoured county before people generally are advised to plant. I think Mr. Marnock's opinion worth a good deal, and

Canon Ellacombe's too. I have seen many little Surrey and Kent gardens during the past few years, and never saw a really good Grape; but it is extremely rare to find that any attention is given to the Vines.—W. R.

UMBRELLA-SHAPED FRUIT TREES.

A FEW years ago this plan of training was very popular, but now one rarely meets with trees so treated. The fact is, a tree trained in the form of an umbrella is, to say the least of it, unnatural. Strong shoots spring up in the centre and starve the depressed and most fruitful branches; the fruits become speckled, small, and worthless, and although this was partly got over by removing the shoots in the centre, trees thus trained were not satisfactory. A few years ago I had some such trees come under my care, and the little fruit which they bore was so deformed and worthless, that it was difficult to determine to what variety the trees belonged. The first row happened to be Beurré Bose, one of the best of market Pears. In its case I left all the young shoots to grow for another season without any pruning, and by the end of the second year the trees had fine heads bristling with flower-buds. These we thinned out, and cut away all the old spurs and useless wood from the centre, and by repeating this process we have now some of the finest and most fruitful trees I have ever seen. The crop, both this and last year, amounted to about three bushels each tree, all fine marketable fruits without speck or blemish. Now, beyond not being pruned, thereby retaining a much larger amount of wood and leafage than hitherto, these trees received treatment not different from that to which they had previously been subjected. Their roots were neither lifted nor pruned. They were merely mulched, and the surface of the ground was lightly forked. Now they have made heads as large as we like to have them, viz., accessible in all parts from a pair of folding steps about 4 feet high. We now stop them in close, for all the shoots are of equal strength. It is surprising how such training as the umbrella form ever became popular. The shoots require no bending down to render them fruitful. J. G. H.

Forking amongst fruit bushes.—Much harm is often done by forking amongst small fruit bushes, the digger often considering it to be impossible to kill a Currant or Gooseberry bush, and at this season, when manure is spread over the soil above the roots, it is frequently forked or dug in regardless of the damage done to them. Indeed, I have known youngsters to be put amongst fruit bushes to dig when they could not be trusted anywhere else. There is, however, a right and a wrong way of manuring fruit bushes, and the right way is never to mutilate roots, or as few of them as possible. The finest small fruits I ever saw were growing on bushes where no fork or spade had been used for years. They, however, received a mulching of manure on the surface after they were pruned in winter, and this treatment is that which they like above all others. Raspberries, too, are very impatient of having their roots disturbed, and mulching them is the only safe way of dealing with them.—CAMBRIAN.

Raspberries in odd corners.—There is a continual demand for subjects which will grow and prove profitable in odd corners and waste places, and the Raspberry is better adapted for such positions than any other fruit with which I am acquainted. The rubbish heap here is a little way removed from the kitchen garden, and underneath trees. The soil is anything but good; nevertheless, some old Raspberry roots which had found their way into it have become established, and not only grow luxuriantly, but fruit profusely every year. I know of instances of the same kind elsewhere, and from the satisfactory manner in which they grow in such cases it is to be regretted that anyone should give up good ground to Raspberries. In some parts the woods abound with them; this is notably the case at Drumlanrig, as I can well remember when a boy there assisting to

gather bushels of fruit from them, and I have never seen any better coloured or more juicy Raspberries since then. When "doing up" Raspberries in the garden there are generally many suckers to remove, and if these are planted in odd and waste corners their owners will soon be astonished at the result.—J. MUNN.

ORCHIDS.

THE DOVE ORCHID.

It is mentioned in THE GARDEN that this interesting Orchid has lost favour with growers, because it does not bloom freely. With me it is the freest blooming Orchid I have, and I find no difficulty with it in any way. Last year I had a plant of it that the year before made three large bulbs. On these three bulbs I had five flower-spikes which stood 5 feet 10 inches in height and carried over thirty flowers each, which lasted three months. Those first opened were very large, but they got smaller towards the top. All, however, made excellent button-hole bouquets. I know of no flowers that last so long after being cut as those of this Orchid. I have often sent them through the post long distances, and yet they come out fresh, and have been used for button-holes for a day or two afterwards. I certainly should not advise plants of this Orchid to be grown in 6-inch pots, a size which some have recommended for it. Some of my bulbs would well-nigh fill such pots; still, it is interesting to know it will flower in such small pots. Until within the last year or two I had but one plant; I have now broken it up into some eight or ten plants, and they are growing well, but too late to make the bulbs which I should like them to make for flowering next autumn. I find that even the oldest bulbs will throw up growth either on the top of the bulb or at its base. I have bulbs which I know to be eight or nine years old that have thrown up growths. When I had two or three small bulbs sent me some ten or eleven years ago, I knew nothing as regards their cultivation, and cared little about them; they were potted much as I potted *Paneratiums*, with which they were associated, and no two plants in the stove have given me more satisfaction. The soil used for the *Peristeria* was perhaps a little rougher than that for the *Paneratium*. It was much the same as that used for *Phaiuses*. The latter were grown in 12 inch pots, and each plant gave me nine spikes of bloom, which I have not had since; but it must be remembered I have not grown them plunged in bottom heat. I know that I am not following the rules of those who teach us how to grow such plants, but it is a fact that *Phaiuses*, like *Eucharises*, do best in bottom heat until, at least, they have made their growth. I have not tried the *Peristeria* in bottom heat. Possibly it would suit it to start it in that way. I committed a mistake last year in regard to the soil in which I potted it; I used too much peat. My loam is very bad, and I thought I would try more peat, but the results are, that my plants have not done so well, and the bulbs are small. My plan is to pot high, place a heavy coating of Moss on the top of the soil, and to give weak manure water once or twice a week. I cover the big, white, worm-like roots as they make their appearance through the Moss with more of the same material. If the plant is in a large pot the bulbs get proportionately large. Never let the plant want for water at the roots, and give a gentle dewing overhead after bright days. Shade but moderately while the plant is growing, and do not be afraid of moisture around it; expose it to the sun and a drier atmosphere afterwards, and give less water, so as to induce rest. If I had to start a bulb just sent me, I should pot it in very rough soil consisting of two parts sandy loam, one part leaf-mould—not fine, but rough—one part Mushroom manure, some charcoal, and a few inch bones placed in a well-drained pot. I would give but little water until it had started fairly into growth. I would keep the atmosphere moist, but I would not syringe overhead until the foliage was a good size. If surfaced with Moss, as stated above, it will be found that the plant will grow all the better for it.—J. TAYLOR, *Huddrick Cottage, Shrewsbury.*

The excellent illustration of this interesting plant in THE GARDEN (p. 374) should, I think, in-

crease its popularity. In no case have I seen it better cultivated than at Belmont, near Taunton, where there is a large specimen of it, which flowers every year in a most satisfactory manner. Every year the bulbs increase in size and numbers, and the flower-stems rise to a height of 4 feet and 5 feet. This plant makes its growth in a high temperature in which it gets plenty of atmospheric moisture, and it should be given a liberal supply of water at the roots. Then follows a good rest in a lower temperature, with a reduction in regard to moisture both at the roots and in the atmosphere.—J. C. C.

FERNS.

VARIEGATED MAIDEN-HAIRS.

VARIATION amongst Ferns is chiefly confined to the forms of the genus *Pteris* and to species of Maiden-hair. Some fifteen years ago variegation was detected in *Adiantum cuneatum*. Part of a plant of it was streaked and splashed with pure white, and some of the pinnules were regularly marked. The variegation in this case being very pure, and the ground-colour on which it appeared being intensely green, the effect was very striking. The plant was put aside, but by some means or other disappeared, and, I presume, was lost. Some four years later a robust-growing variegated seedling of *Adiantum concinnum latum* made its appearance, but owing to the naturally pale yellowish green tint peculiar to the foliage of that species, the streaks, which were numerous, but of a creamy colour, were not sufficiently distinct to make it a plant worthy of attention. Next came a prettily-marked form of *Adiantum decorum*, the pinnules of which were all freely streaked with a greyish white colour; but, though very interesting while young, it assumed when old a certain dingy appearance, which precluded its being propagated and distributed. *Adiantum Veitchi* frequently shows symptoms of variegation, and I have often noticed in various places plants of that species whose pinnules were partially streaked with creamy white, but, notwithstanding the fact that in several instances these striped pinnules were carefully selected and their spores sown separately, none to my knowledge ever produced really variegated seedlings. Some five years ago I received from the Continent two fronds of *Adiantum formosum*, both of which were copiously marked with yellow. These markings, however, did not partake of the character of either stripes or spots; on the contrary, the fronds were more or less splashed with a sort of stone colour, and if the effect thus produced was not exactly beautiful, it was nevertheless very striking, and certainly quite unusual. This species of Maiden-hair being readily propagated by division of the fleshy underground rhizomes peculiar to this Australian species, I fully anticipated that, even if seedlings should fail to reproduce the splashed character inherited from the parent plant, we should ere this have seen this curious plant distributed, but I have heard nothing about it since. The variegated form of *Adiantum macrophyllum* raised at Montmorency, and alluded to lately in THE GARDEN, is, however, a much more striking plant than any of those named above. It is therefore to be hoped that it will reproduce itself true from spores, as in this case propagation by division of the crowns is a slow as well as a risky operation. The reason why I consider a variegated form of *Adiantum macrophyllum* of greater value than any of the other species just named is, because the pure white streaks on a bright green ground are sufficiently numerous to render the plant attractive, but not at all sickly looking; and also because its pinnæ, instead of being minute, like those of *Adiantum cuneatum*, *decorum*, *concinnum latum*, *Veitchi*, &c., are of very much larger di-

mensions, and therefore possess a degree of effectiveness which is not shared by species with small pinnules. When in a young and partially developed state, the foliage of the species from which this new form has sprung is very pretty, and deservedly much admired on account of a bright pink tinge which it has, and which is particularly noticeable in the variegated form. Let us hope that in this case the variegation, which is so bright and so distinct, will prove constant; and that, on account of its easy culture and rapid growth, this beautifully variegated Maiden-hair will before long be included in most collections, where it cannot fail to form a striking and pleasing contrast with foliage of Maiden-hairs of a darker hue. S.

FIRST IMPRESSIONS OF ALBANY, WEST AUSTRALIA.

THE following extracts from a letter written by my brother, who has recently gone out to West Australia, may possibly interest some of the readers of THE GARDEN: "The most glowing accounts which we had of this place were not in the least overdrawn. It was early morning when we dropped anchor, and so we missed the view of the outer harbour—King George's Sound. For the first few days we had unfavourable weather, cold and showery; but now (October) it is lovely—pure, bright sunshine, most gladdening and inspiring. No wonder this is such a paradise of flowers. I have likened the place to Oban, that is, of course, taking a general outline view of it. The town nestles at the foot of two, fine bold hills, with great granite rocks cropping out here and there. Large crags in profusion exist close up to the town. Except in Stirling Terrace, the houses are scattered here and there, and the vacant blocks of land are fenced in roughly with split Jarrah—everything is Jarrah: wardrobes and clothes-props, pews and telegraph-poles, kerbs (in the streets), and logs for the fire. We have not seen a coal fire since we left England. The rough fencing I am describing is universal; brick walls are unknown, so are iron palisades, and consequently these half-fledged towns have the untidy appearance peculiar to the colonies, but there are saving clauses. Out of the window I look across the main street, 100 feet wide. Half of it is a good, hard, well kept road; the other half is a grassy bank sloping down to the boundary fence; such a mass of great Arum Lilies runs along it as would open your eyes if you could see it. Great patches of them are plentiful all over the town; such beauties they are, too. There is a corner of two of the principal streets near where we are staying—such a picture. A great clump of these Lilies and a fine *Pelargonium* almost cover up the fence. *Pelargoniums* of different kinds take the place of Nettles. A lilac one is very common, and grows 10 feet or 12 feet high. One of our fellow passengers brought out a box of *Pelargonium* cuttings, which he tended with great care. He meant to introduce this useful plant to the colony. Imagine his disappointment, on landing at Freemantle, to find *Pelargonium* trees in all the back yards and out-of-the-way corners. Here they bloom all the year round, and grow in nothing but sand, too. I measured a bush of *Heliotrope* growing under the windows of the house next to the one I have taken and found it to be $4\frac{1}{2}$ feet thick and 5 feet high, and finely scented. Fruit trees, I am told, do not answer here. They have been tried and have failed. I have inspected some of them; they were put in as an experiment about fourteen or fifteen years ago, and it is admitted that they bore abundantly for some time. They are now full of bloom, but 'don't bear as they used to do,' and no wonder. They have never been pruned since they were planted, and have rambled up like wild Apples. The fruit does drop off, and can be picked up without much trouble, but as for pruning, good gracious! who is to do it? Fig-trees are a success and bear well. We look out upon a weird tract of partly civilised 'bush,' but far away in the distance we can just see very fine mountain peaks. Our garden, we are told, is famous for its productive powers. There are Peach, Apricot, Pear, Mulberry and other trees in it showing promise

of good crops. Peas and Beans are in full bloom. We have a few small Rose trees with fine foliage and good looking buds, a mass of a charming white climbing Rose, one or two specimens of a variety of Aloe or Yucca, evergreen Pelargoniums, and many beautiful flowers strange and new to us. People here do not care about gardens for two reasons—they won't take the trouble to put seeds in the ground, and all round about is a most exquisite garden, with flowers in endless profusion. At every step we take, even in the limited area we have seen yet, we come across a new Grass, or some queer, odd shaped blossom of a pretty shape or colour. It is, however, beyond my power to give you an idea, even of the flowers, which we have here." T. E. F.

FLOWER GARDEN.

SHOW AND FANCY DAHLIAS.

WHAT is a show, and what a fancy Dahlia? It is only those who grow Dahlias for sale or exhibition who can give answers to these questions. A Dahlia that has a white or bluish base, and has the petals tipped with purple, red, scarlet, &c., is classed with the show varieties; but one that has the ground colour purple, red, scarlet, yellow, &c., and is tipped with white is a fancy Dahlia. All flowers having stripes or flakes of colour on any ground are also classed among fancy flowers. One of the best definitions of a fancy Dahlia with which I am acquainted was given a quarter of a century ago, when the dividing line between the show and fancy varieties was more clearly demonstrable than it is in the present day. It ran thus: "To the composition of a fancy Dahlia, two (or more) distinct colours are essential, if the variegation is in the form of stripes or flakes, as in the case of Carnations. This arrangement of colours, whether the light or the dark preponderate, is in itself sufficient to constitute the sub-division distinguished as striped fancy Dahlias; but if the variegation consists in the edges or tops of the florets differing from the general or ground colour, then the relative position of the colours determines whether the individual is a fancy flower or otherwise. Thus a white, yellow, or any pale variety, edged, tipped, or laced Dahlia with a dark colour, after the manner of the Picotee, is denominated simply an edged, tipped, or laced Dahlia, and is placed in the show section; but when this disposition of colours is reversed, *i.e.*, when the florets of a dark flower are tipped or edged with a light colour, the variety so marked is termed a tipped fancy Dahlia." Whether this definition is sufficiently clear to be understood by readers of THE GARDEN is open to doubt; but it is understood by those who grow collections of both fancy and show varieties. The fact is, the development of the fancy Dahlia (the first of the type having originated in France or Belgium) is of a much later date than the show variety; and, for a time, they were inferior both in size and build. It was some time before they were recognised as up to show form, but when classes were made for them in schedules of prizes, it was found expedient to exhibit them by themselves. But mainly owing to the efforts of the late Mr. John Keynes, the fancy Dahlias, during the last fifteen years, have so increased in size, substance, and form, that they are now on a level of quality with the show flowers so called; more than that, the original lines of distinction between the two have become so obliterated in course of time, that it is now becoming difficult to say what is and what is not a fancy Dahlia, and if experts find it difficult to correctly classify flowers, the outside flower-loving public must be considerably at a loss to do so.

This fact is being so borne in upon the minds of some of the promoters of the National Dahlia show, which is held annually in September at the Crystal Palace, that at a meeting held at the Botanic Gardens, Chelsea, a few days ago, proposals were made to abolish the distinction between show and fancy Dahlias in the schedule of

prizes for next year. It was suggested that the show and fancy varieties should be fused in one group for exhibition purposes; and that they should for this purpose be formed into two main divisions—self and shaded and parti-coloured flowers. Some were for going a step further, and for putting aside all distinctions, leaving exhibitors to show what they pleased—show and fancy both, or only one of these. This proposal was largely supported by the trade growers, but it was by no means favourably entertained by the amateur exhibitors present. Eventually a compromise was arrived at, and it was agreed that the nurserymen's classes should be open to all varieties included under the head of show and fancy, and a new class was formed—one for seventy-two Dahlias, in not less than thirty-six varieties, and not more than two blooms of any one variety. This will enable those who take an interest in the matter to judge of the effect obtained through exhibiting show and fancy varieties on the same stand. There will be classes also for forty eight, twenty-four, and twelve blooms, in which any blooms can be staged. In the amateurs' classes throughout the schedule the old distinction between the show and fancy Dahlias will be maintained.

In order to further illustrate this new classification, open classes will also be provided for. Six blooms of dark Dahlias, distinct; six light ones, six tipped ones, and six striped ones; these will not only introduce what promises to be an interesting feature, but also enable those interested in the Dahlia to gather some idea of the best flowers of the particular types required. A new class is also provided for six varieties of Cactus, or decorative Dahlias; six blooms of each to form a bunch. The single Dahlias shown in bunches have proved such an attractive feature that it has been determined to create a new open class for twenty-four varieties, and that for six varieties, hitherto open, will be reserved for amateurs. The promoters of the Dahlia show at the Crystal Palace are to be commended for their courage in breaking away from the old traditional method of classifying Dahlias. Such a step was necessary; and it is to be hoped it will be carried still further another season. At many country shows, tipped flowers, whether show or fancy, are exhibited among the latter, and it is a course sanctioned by custom. This proves that the term fancy is not generally understood, and in the face of a clearer definition of the term than has yet been given, its entire abolition is decidedly necessary in schedules of prizes. But dealers in Dahlias are at full liberty to classify them in their catalogues in any way they please, and to divide them into as many sections as they see fit to do so.

Under the old classification, the following list, furnished by Mr. Harry Turner, gives the best thirty-six show Dahlias, fancies being, of course, excluded, *viz.*, Burgundy, Clara, Constance, Flag of Truce, George Rawlings, Georgiana, Goldfinder, Hope, Henry Walton, Herbert Turner, Imperial, Hon. Mrs. P. Wyndham, James Cocker, James Stephen, James Vick, John Bennett, John N. Keynes, John Standish, Joseph Ashby, Jos. B. Service, Lady Gladys Herbert, Miss Cannell, Mr. G. Harris, Mrs. Gladstone, Mrs. Langtry, Mrs. Harris, Mrs. Shirley Hibberd, Harry Keith, Mrs. G. Rawlings, Prince Bismarck, Prince of Denmark, Ruby Gem, Sunbeam, Seraph, T. J. Saltmarsh, and William Rawlings. For the benefit of cultivators of small collections of Dahlias, I give the following as the best twelve selected from the above, *viz.*, Clara, Constance, George Rawlings, Hon. Mrs. P. Wyndham, Mrs. Langtry, Mrs. Gladstone, Miss Cannell, Mr. G. Harris, Sunbeam, Prince of Denmark, Mrs. S. Hibberd, and Prince Bismarck.

And as the schedule of prizes of the next National Dahlia show at the Crystal Palace will contain classes, as stated above, for flowers of similar character, but distinct in variety, it is well to name a dozen good and constant self and shaded flowers as follows: Clara, George Rawlings, James Cocker, Imperial, John N. Keynes, Mr. G. Harris,

Joseph Ashby, Mrs. Gladstone, Prince Bismarck, Seraph, Prince of Denmark, and Sunbeam. As prizes are also to be offered for tipped Dahlias, it will be well to give a list of these, and the best twelve of the show class will be found in Constance, Goldfinder, Hon. Mrs. P. Wyndham, John Bennett, Miss Cannell, Mrs. Langtry, Mrs. Harris, Mrs. S. Hibberd, Ruby Gem, T. J. Saltmarsh, Henry Walton, and Mrs. G. Rawlings. The best twelve tipped fancy Dahlias are as follows: Fanny Sturt, Laura Haslam, Miss Browning, Mrs. N. Halls, Mrs. Saunders, Peacock, Jessie McIntosh, Lady Antrobus, Mrs. Carter, Maid of Athens, Mrs. Frisleton, and Miss Rodwell. As there is a class for striped Dahlias also, it may be remarked that these must be looked for exclusively among the fancy flowers, and the best dozen is as follows: Charles Wyatt, Duchess of Albany, Gaiety, George Barnes, Henry Eckford, Hugh Austin, Henry Glassecock, John Forbes, Rebecca, Rev. J. B. M. Camm, Professor Fawcett, and W. G. Head. In the class for light Dahlias, self, yellow, and white, and blush, buff, pale pink, and delicate lilac flowers can find a place, and a good selection of twelve will be found in Clara, Condor, Emily Edwards, Ethel Britton, Flag of Truce, Mrs. Gladstone, J. N. Keynes, Muriel, Seraph, and Sunbeam.

Nor must lists of the best fancy Dahlias be omitted. A first-rate twenty-four will be found in the following selection: Charles Wyatt, Duchess of Albany, Edward Peek, Fanny Sturt, Frederick Smith, Gaiety, George Barnes, Grand Sultan, Henry Eckford, Henry Glassecock, Hugh Austin, James O'Brien, John Forbes, Laura Haslam, Mandarin, Miss Browning, Mrs. N. Halls, Mrs. Saunders, Peacock, Professor Fawcett, Rebecca, Pelican, Rev. J. B. M. Camm, and W. G. Head. The best twelve, selected from the foregoing, are Charles Wyatt, Duchess of Albany, Gaiety, George Barnes, Henry Glassecock, Hugh Austin, John Forbes, Miss Browning, Mrs. N. Halls, Professor Fawcett, Rebecca, and Rev. J. B. M. Camm.

R. D.

NOTES ON HARDY PLANTS.

Stonecrops.—I grow about sixty varieties of Stonecrops in two small, square beds, and from July to the end of the flowering season they are literally alive with bees, large flies and painted butterflies. Whilst on Stonecrops, may I speak of two distinct and late-flowering kinds; first there is the charming, dwarfed, fat-leaved and mealy *Sedum brevifolium*, which has white flowers of a pleasing tint, somewhat in the way of that of *S. album*. This is not one of the hardiest of Stonecrops, but it will endure our lowest temperatures if kept dry, and therefore it is well adapted for growing in stony chinks where there are overhanging ledges, but wherewithal it should not be shut off from sunshine. The other variety is the one commonly known as *S. atro-purpureum*; this is a tall, big-leaved kind, not unlike *S. spectabile* in form and size of leaf, but the corymbs are not so flat. The flowers are very peculiar. I do not think that I could compare them to anything better than a shield of golden filigree. The corymb is nearly the size of the palm of one's hand. The leaves and stems are of a fine purple colour, suffused during summer with a glaucous hue. This is a Stonecrop, so far as I know, seldom seen; anyhow, I have never seen it except in one of the many collections I have visited. As a quaint and effective plant it may certainly be recommended, whilst the flowers, so singularly beautiful, are not only capable of enduring rough weather late in the year, but they form chaste material for personal adornment. The plant is as hardy as can be, but I should observe that before it can flower freely it has evidently to get well established at the root. During summer several parties made a note of this plant for bedding purposes, owing to the distinct form and colour of the foliage. To my mind, however, the somewhat top-heavy stems would not favour its use in that way, but still, by pinching, it could be kept dwarf.

Megasea purpurascens when in full leafy beauty is one of the brightest bits of colour in the garden; bronzy red, yellow and vermilion are

colours which may all be seen on one and the same plant, and where numbers of plants are grouped together the effect is most attractive. The red vies with that of the cardinal Lobelia. As I have said before in THE GARDEN, such results can only be had under special treatment. I may mention, however, that several clumps of the same stock are grown under other conditions, with the view of getting more rapid growth, bigger foliage, plump crowns and large scapes of bloom in spring. At present the foliage on those plants is as green as that of a Cabbage; the conditions of culture are deep, rich soil, a somewhat moist position, and a little side-shade from the mid-day sun. For bright autumn foliage the plants should be set in a thin soil, very porous, and be exposed to all the sunshine possible. Plants so treated, I need hardly say, do not flower like the others; in fact, though I have grown the variety for more than ten years, I never had a good scape of bloom on such plants as were grown in poor soil. I grow some seven varieties of *Megaseas*, and of these there is certainly not one to be compared with *M. purpurascens* for beauty and intensity of colour. It is, however, a shy bloomer unless very liberally treated.

Primula capitata.—I mean the true mealy, wrinkled leaved and finely-toothed species, and neither of the forms of *denticulata* nor of *esbmeriana* which are sometimes called *capitata* and supplied from trade sources. One of its most commendable qualities is that it flowers in succession until late in the year, but as to the size of the heads and pips which it is capable of producing, I must confess I was in ignorance until a flowering specimen was kindly sent me two days ago by Mr. Wolley Dod. The scape was as stout as an ordinary lead pencil and 15 inches high. The farina was abundant, and the scent like that of a bunch of *Polyanthuses*. Other scapes were in a forward state and many less developed. The plant had soil adhering—evidently a rich retentive loam and leaf mould. The specimen was not nearly a year old, seed having been sown last February. This is, without doubt, the way to cultivate *P. capitata*.

Cheiranthus Allioni is the name under which a most charming dwarf Wallflower came to me above a year ago; just at present I cannot give its history, but I hope soon to be able to do so. Having fully tested it both in the open garden and in pots fully exposed (which I always consider a more severe test of hardiness than open-ground planting), I can speak as to its capabilities to withstand such trials as those of last winter, and it seems as if it would be a good perennial. Compared with *alpina*, it has a less dense habit, fewer leaves, but they are much longer, distantly and distinctly toothed, and of a deep green hue. It is about the same stature, but more slender. The flowers are a deep orange-yellow and not variable, at least not in the dozen or so of plants which I have flowered. Compared with Marshall's variety, the flowers are far deeper in colour, but they are arranged quite differently, not clustered, but in lax spikes more like those of the common Wallflower. I may add that the colour nearly resembles that of the brilliant annual, *Erysimum Peroffskianum*. It is a spring bloomer, but there was a good sprinkling of flowers all summer on the stronger plants.

Tropaeolum tuberosum.—When I wrote about this rampant grower blooming sparsely I did so from a specified standpoint—that of cultivating the plant under such conditions that it might be wintered out of doors. In Yorkshire, unless grown in a hot and dry situation and in poor soil, my every year's experience is that the flowers are few and late compared with the amount of growth made. I can well believe that plants in partial shade, and growing in heavy clay, as stated by "Greenwood" (p. 468), might, in a dry summer like the past, flower well, for is it not the case that, under and near trees, the land is invariably in an extra droughty condition when the weather is at all dry? And likely enough the tops of the plants would find their way up to the sunshine.

* * The plant flowers freely in many parts of the southern counties.—ED.

Aster spectabilis.—This, I think, is a good variety in all respects. It is in the style of *Amellus* and its varieties; if the heads are less than those of *Amellus*, they are much more highly coloured, or the purple has less red in it. I do not know another *Michaelmas Daisy* so blue, and I have been seeking for the highest and most distinct coloured varieties for three years. The one sent me as "*Mr. Dod's bluest*" is truly handsome, but it does not approach *spectabilis* as a blue flower, and, indeed, is a very different *Aster*.

Hepaticas.—It is all very well to grow these into large clumps, and nobody can question that, in that condition, when in flower, they are most effective, but it is just as certain that where *Hepaticas* do well, they outgrow their healthy condition in a few years. We often speak of clumps a foot across; when we do so, I suppose we mean that the flowers and foliage form cushions of that diameter. The actual clumps or cluster of crowns of such clumps may not be more than from 6 inches to 8 inches across, and under suitable conditions they may grow to that size in four years. At the end of that time, however, it is a question whether it is wise to leave them undivided; besides, all *Hepaticas* have a habit of growing too high above the surface, and it is well to place them deeper at intervals. It has long been our rule to do this, and we always see our finest *Hepaticas* on two-year-old divisions.

Christmas Roses.—It has frequently been argued as to which is the best time to divide and replant *Christmas Roses*. If we would permit ourselves to be guided by what we may observe in the way of root-action, I do not think we should hesitate in doing the work at a time which, I daresay, to many will appear somewhat unreasonable—*i.e.*, just previous to the flowering period. I know well that many would object to cut up their plants at the moment they were anticipating a floral treat. That, however, is not the question; the question is, as to when the roots may not only be safely, but better divided for their subsequent healthy growth. If the roots are examined at the present time, there will be found a set of young succulent roots bristling from immediately below the junction of the leaf-stalks. These are the parts we want to catch, and, without breaking, place in new and well-prepared soil. If we succeed in doing this, we shall not be annoyed with plants remaining dormant for a year or more afterwards; but, in most cases, if the divisions have been judiciously made, there will not only be a good plant, but the flowers will come forward in a natural way. It is unwise to attempt such operation, except with the healthiest plants. I have just had occasion to remove some divisions that were planted only a fortnight ago, in order to clear a space for the men to dig out some large shrubs, and it was pleasing to see what vigorous root-growth there had been in that short space of time. I daresay we could hardly have had finer weather for the season during the period—plenty of moisture, a fair share of sunshine for November, which, with the leaves off the trees overhead, had its full effect on the *Hellebores* in the freshly-dug soil. J. W.

Three good wall plants.—The walls of the flower garden at Penrhyn Castle were lately rendered particularly attractive by the number of flowering shrubs with which they were clothed. Three of these, including *Lapageria rosea*, *Abelia rupestris*, and the small-leaved *Myrtle*, were grand in the extreme, and assisted in a marked manner to impart a gleam of floral sunshine, so to speak, to the wintry landscape. Not long since I counted quite a hundred flowers and more on the *Lapageria*, and they hung in such an easy and conspicuous way, that even the most unobservant of visitors were tempted to stop and admire them. The pretty, deep green, five-nerved leaves, too, showed off the large, campanulate, deep rose-coloured blooms to perfection. The *Lapageria* may, I think, be considered to be almost perfectly hardy, for it has stood in its present position at Penrhyn for a number of years, and quite unprotected. The Chinese *Abelia rupestris* likewise makes a good ornament for any garden wall, its pretty pairs of pinkish white flowers and reddish tinged

calyx-lobes rendering it of special interest. Whether or not it is to be considered hardy, I cannot say, but here it does well, and when in flower rivets the attention of most passers-by. It is perhaps unnecessary for me to allude in terms of praise to that charming shrub, the small or Box-leaved *Myrtle*, but I do so in the hope of extending its culture, for certainly as an ornamental and neat wall-coverer it stands in the first rank amongst such plants. To see it as it has been for the past half-year or so is a treat both rich and rare. I fancy somehow that this small-leaved form is a later flowerer than the typical plant; such, however, is the case here. Let everyone who wants a good and pretty wall shrub, plant this *Myrtle*.—A. D. WEBSTER.

THE PAMPAS GRASS IN SUSSEX.

A STately mass of Pampas Grass in full plume is always a beautiful sight in a garden, and particularly if so placed that the surroundings heighten its effect. In such a position is the noble specimen in Mr. Gatehouse's garden at Chichester, who kindly sent us a photograph of it, taken last season by Mr. Malby. It was then exceptionally fine, the great mass of plumes being nearly 10 feet high. It is planted in a part of the garden snugly surrounded by trees. Close to it is a stone-edged water basin and fountain, so that this corner is a pretty feature of the garden. The ring of flowering plants around the base of this Pampas is decidedly a mistake; such a stately plant as the Pampas needs no embellishing, and it never looks better than when seen rising from a lawn with room to spread out its Grass in a graceful way. The soil about the plant can be now and then enriched in the same way as when a circular bed is made around it. Mr. Gatehouse's Pampas is of the best variety, the one that produces large spreading white plumes. There is such a great difference between the good and the bad varieties of the Pampas, that care should be taken to get the best form, seeing that the plant always forms an important permanent feature of a garden, if it succeeds, and one that takes a long time to develop, and which is so difficult to replace.

Carnations and Picotees.—Anyone having a collection of young plants of Carnations or Picotees in a cold frame should look over them occasionally, to see that all decayed and decaying foliage is removed, and it is good practice to occasionally lightly stir the surface soil, *i.e.*, if not frost-bound. Mr. E. S. Dodwell, in his book on the Carnation, lays down the following rules for the guidance of young beginners in winter: "Give plenty of air; never, indeed, close the frames or house day or night, excepting during the severest frosts; and thoroughly cleanse every plant from decaying foliage and dust. In my experience, no severity of cold has been injurious to Carnations or Picotees unless the plants have been previously made tender by injudicious confinement, but guard sedulously against cutting icy winds. During long-continued severe frosts, one, or at most two, mats will be ample protection. These should be allowed to remain on during the daytime to prevent excitement from the brighter light usual at such seasons. Do not, however, exclude air; tilt the lights of the frames and open the windows of the house on the leeward side." In potting up layers, it has been discovered that a small whitish maggot, not unlike in appearance the Apple maggot, but much smaller, is doing serious damage to many of the plants. It would seem from appearances that the eggs, or whatever it may be from which the marauder springs, are deposited in the leaf, and when the pest emerges into activity it bores its way through the sheath of the leaf, and eats its way along the centre inside. It appears to enter the shoot of the plant in much the same way, and gradually finds its way to the base, completely destroying it, as it rots off at the collar close to the soil.—R. D.

GLADIOLI IN AUTUMN AND WINTER.

I CANNOT agree with "Delta" when he says that he would rather grow Gladioli in the east than in the west of England, and especially when he says that they ripen earlier and better in the east than in the west. My experience is that early ripening is not advantageous, but the contrary. It is my belief that Gladioli are weakened more by being kept out of the ground too long than from any other cause. The impatience which the bulbs display by starting into growth, when stored in dry sand and kept in a cool place, shows that it is not natural for them to rest so long. When thus treated they begin to make roots, and even leaves, early in February, although not harvested until the middle of November, and often later than that. I have even had them exposed to 10' of frost before they were lifted, and without any harm being sustained. This tendency to start into growth so early is, no doubt, against them when transferred to cold, damp ground in spring, yet it evidently points to the conditions which they require. I am aware that "Delta's" advice to store them in paper bags is the proper way to keep them dormant, and thereby prevent the necessity of planting until late in spring, but that plan of storing does not appear to me to be Nature's way. In this opinion I am supported by the behaviour of bulbs left all winter in the ground and efficiently protected. These are always the first to make their appearance in the spring; they produce larger flower-spikes, and keep healthy and vigorous all the summer. I shall not soon forget the luxuriant condition of a large bed of Gladioli which I saw at Powderham Castle, near Exeter, in early autumn three years ago, and on previous occasions. The plants were in the most robust health, and producing grand spikes of flower, with very few, if any, failures. If I remember rightly, Mr. Powell told me that he only took up the bulbs when they wanted dividing. They were wintered in the ground under a thick layer of leaves and litter. We must not forget, too, that the climate of Devonshire differs a good deal from that in other parts of the country. At the same time, such an instance serves to show that the more natural the conditions under which we can keep the bulbs in winter, the better. I do not mean to say, however, that they can be kept safely in the ground in any but the most favourable soil and climate; they cannot be trusted even here in Somerset unless well protected, and then more rot through damp than actual cold. With regard to soil, I am of "Delta's" opinion that they do better in a fairly heavy soil than in a light one; the ground,

too, should be lightly manured with rotten hotbed or farmyard manure early in winter, and deeply dug up so as to get the surface well pulverised before the planting season comes round. J. C. C.

White Everlasting Peas.—In reply to Mr. Poc's enquiry (p. 563) as to the certainty of these reverting to the pink form, allow me to state that there could be no doubt about the matter, as they were planted in a small enclosed garden separated

summer can ill afford to dispense with it, and therefore some little trouble taken to keep it true is well repaid.—J. GROOM, Gosport.

REMARKS ON HELLEBORES.

It is to be expected, and also wished, that Hellebores should at this season once again claim some notice in THE GARDEN. Two such notices appear in last week's issue (p. 580). "G." is fully justified in all he says concerning the beauty and value of *H. niger maximus*. I would remark only that the roseate tint on the sepals ought not to be made an invariable accompaniment, but that, beautiful as that tint may be, the most perfect growth produces pure white. Secondly, he would omit *niger* in his nomenclature, but I think that would be a mistake, since *niger* is as essentially descriptive of one group as *orientalis* of another, and *viridis* of a third, &c. The next notice is by "O." I do not remember that "O." has hitherto taken any part in the many discussions concerning Hellebores of recent years, but he must excuse me if I suggest that he ought to give some authority for differing from those who have come to an agreement as to species, names, colours, &c. First, as to crosses. I am not aware that crossing has been generally restricted, as he says; a much more general crossing than he mentions has been carried on with most interesting results—persistents with non-persistents, as well as like with like; but when he particularises a cross between *orientalis* and *niger*, I am sure all Hellebore growers would be glad to hear of anyone who has been successful in obtaining appreciable characteristics of *niger* by crossing with any other Hellebore. I pass by the idea of making *niger maximus* rather than *niger* the type of the group, but I must say a word in favour of *niger minor*, which is not only very pretty, but valuable, as being by far the earliest in bloom. Then, again, *H. orientalis* is not deciduous, but truly persistent in its foliage. *Abchasicus* is not green, but purple, with a white variety; whether or not *atrorubens* is the same plant is doubtful, but both belong to the persistent group, and *purpurascens* is different in every particular, belonging to the non-persistent section. I make no comment upon the time of flowering, as that depends on locality and season. My only motive in making these remarks is to save those who are only commencing to grow Hellebores from being more and more confused by those who write on the subject. South Devon, T. H. ARCHER-HIND.

Pampas Grass in Mr. Gatchouse's garden at Chichester, Sussex. Engraved from a photograph for THE GARDEN.

by walls from any other of the Pea tribe. They all produced white flowers the first season after I purchased them. If they had been seedlings, I should not have been at all surprised, as it is pretty conclusively proved that seeds of the white form produce a rather large percentage of red-flowered plants. The white is such a desirable plant, that those who require white flowers in

Dracæna indivisa out of doors.—Although this plant is so largely grown under glass, I am

enabled to say that it is quite hardy in our southern and western counties; at least, we have some plants of it that have stood out of doors fully exposed, without any protection whatever, during the past three winters. The soil around their roots has been hard frozen on several occasions, yet not a leaf has been browned. This *Dracena* is elegant in habit, and well adapted for forming central objects in large beds, or groups in the flower garden, or for single specimens on Grass. Anyone having plants of it that are getting too large for indoors should plant them out in May, so that they may make their growth out of doors and get well acclimatised before winter sets in. Sheltered nooks in shrubberies, or rather recesses on the lawn, make capital places for single specimens of this kind of plant. Tall examples that have long been indoors are exceedingly useful for backgrounds to groups of sub-tropical plants, such as Tree Ferns, Palms, &c., plunged out in summer. They may either be left out altogether, or brought into the conservatory in winter. Large specimens may be kept in good health in comparatively small pots by giving them occasionally a little concentrated plant-food, either in a liquid or dry state; and I need scarcely add that such vigorous-growing plants require plenty of root-moisture, for on the green healthy look of the leaves depends the effect which they produce.—J. G., *Hants.*

5536.—**Daisies on lawns.**—Nothing is better or surer for extracting Daisies than a common three-pronged kitchen fork. Stretch a line across the ground when soft, and root up the Daisies over a given breadth, and roll well after weeding. My lawn-tennis ground was almost a sheet of Daisies. I found when they were extracted that the Grass soon filled up the bare spots. A few Daisies are sure to be left and can be taken up whenever seen. Hurry's Extractor is useful for isolated weeds, not when they grow in patches. Watson's Lawn Sand is a rich manure; it kills nearly all the Clover and some Daisies. Long-rooted weeds, like Dandelions, are only enriched by it; it certainly gives the Grass a beautiful colour. Vitriol dropped on each Daisy kills it, but is apt to poison the ground and prevent the Grass from filling up the blanks.—J. H. W. THOMAS, *Bolton, Carlow.*

— For killing Daisies I can confidently recommend the new destroyer, *Belleide*. It not only destroys Daisies, but other offensive weeds. It is in the form of a powder, and is applied by means of a dredger; it is found by experience that it is best used during moist weather, but if used when it is dry the spot where it is applied should be sprinkled with water five or six days afterwards. In the case of strong plants of Daisies it is best to cut away the leaves and apply the *Belleide* to the stumps; two or three dressings will soon kill the stoutest leaves. In applying it, it is best not to allow it to become sprinkled upon the Grass surrounding the weeds, but should this happen, and the Grass is burnt a little, it will soon recover, for the *Belleide* fertilises the surrounding Grass though it destroys the leaves; and the powder should be kept perfectly dry until it is used. I have seen the *Belleide* used with such good effect at Gunnersbury Park, that I have no hesitation in commending its use. It is by no means an expensive preparation.—R. D.

The Neapolitan Cyclamen.—This is the name of a plant that is invariably found doing duty for *C. repandum* or *C. hederifolium*. The latter name is perhaps the commonest in gardens, and is partly right, but, according to the latest authority on this genus, it was made to include both the spring and autumn-flowering kinds, and in consequence has been dropped altogether, neapolitanum being substituted for the autumn-flowering species and *C. repandum* for the spring one. Several good distinctions of a permanent character exist by which they may be readily recognised; *C. repandum* has the leaves developed when the flowers appear. The latter are rosy red with a bright purple spot at the base, and without an auricle at the mouth; *C. neapoli-*

tanum produces its flowers in autumn before the leaves appear, and it is not until they are going off that the leaves begin to develop. The segments are distinctly auricled at the base, and they are white or reddish coloured and have a violet or purple spot. It is a very charming plant when grown in quantity, and just the thing for a woodland walk. Indeed, it has been naturalised in some parts of the country, and notably in Cornwall, Kent, &c., where it is said to produce enormous tubers a foot or more in circumference, each producing one or two hundred flowers. It has numerous synonyms—*autumnale*, *pyrenaicum*, and *ficariaefolium* being those that are best known. *C. africanum*, another autumnal flowering species, is somewhat rare, but as it is a native of Algeria and produces its leaves just when our hard weather sets in, it would probably not prove hardy in exposed places. *C. europeum*, a well known garden plant and perfectly hardy, flowers from August to October; the leaves are produced along with the flowers, which are usually bright red and very fragrant. It is useful for the rockery, where in sheltered places it flowers profusely. The soil should be free, as also the drainage, and care should be taken at planting time to see whether the tuber is entirely covered or the upper surface left exposed. Some of them root only on the lower half, while others root all over their surface.—K.

PLANTS SUITABLE FOR WALLS.

THE removal of an old shrubbery in order to form a herbaceous border, some three years ago, laid bare an old wall that answered as a background for the border in question, and as it was advisable to clothe this wall as quickly as possible and make it an attractive feature, climbers were planted thickly against it, and allowed to ramble for two or three seasons almost at will. The effect of this last summer, now that nearly all are at the top of the wall, has been excellent. One or two mistakes were made in the choice of subjects, and these have led me to conclude that climbers might with advantage be divided into three or four classes as follows, viz., for flowering and general effect, for cutting and general decorative purposes, and solely for hiding bare and unsightly places. Plenty of flower as well as foliage was required on the wall just alluded to, and the mistake made was in using with other things Banksian and Maréchal Niel Roses. Maréchal Niel does not take kindly to outdoor culture with us, and the Banksians are too strong to mix well with other things. For covering purposes they, however, have no rivals, making yards of annual growth, evergreen to all intents and purposes, and flowering freely when well established. Nearly the same remarks apply to *Ceanothus*, the flowers of which are produced in profusion all through the summer months. The evergreen *Honeysuckle* is also a capital plant for the same purpose. Two plants that are very dense in habit, and also very useful for cutting from, are *Escallonia macrantha* and the variegated *Alaternus*. I would give the last-named a corner wherever there was one to spare, as it is one of the most useful plants we have for vases, and all the year through it is a mass of glorious variegation. It grows very fast, and is in every way a most desirable wall plant. We did not care for deciduous things, but worked a few in carefully and at wide intervals apart. Amongst these were *Chimonanthus fragrans*, *Benthamia fragifera*, and *Forsythia suspensa*. *Deutzia crenata* fl. pl. is a great favourite, and one whose flowers do admirably for button-hole bouquets. In naming a few things that may be planted, I may say that the general effect will be greatly enhanced by allowing them to ramble and intermix both flowers and foliage. Stray branches of *Ceanothus* mix well with *Safrano* and *Gloire de Dijon* Roses, and the white and red *Pyrus* look well mixed together. Another good combination is the variegated Japanese *Honeysuckle*, making itself at home amongst the branches of an old Judas tree. All the above are of easy culture, and by means of them flowers

would be found on walls from very early spring until late in the autumn. With hardly an exception, climbers do best in a moderately stiff loam. The growth is short-jointed and stocky, the foliage more dense, and the flowers produced in greater profusion than in light soils. No hard-and-fast rule can be laid down for pruning these plants. When once planted, the object is, of course, to clothe the walls as quickly as possible, and to attain this end all strong shoots should be laid in their entire length each year until they have reached the top. After treatment must necessarily be influenced by the circumstances of the case. They should have their own way as much as possible, and the knife should not be used more than is absolutely necessary. E. BURRELL.

GARDEN FLORA.

PLATE 577.

ITALIAN BELLFLOWERS.

(WITH A PLATE OF *CAMPANULA ISOPHYLLA*, AND WHITE VARIETY.)*

LITTLE need be said in praise of a genus represented by some of its various forms in almost every cottager's garden, and abundant in our meadows and copses. The section, however, to which we now wish to direct attention is confined to sunny Italy, and is not so common in gardens as the natives of colder climates. In speaking of these Bellflowers, Mr. Moggridge says: "It is a curious fact in the distribution of plants that all the species belonging to the section of *Campanulas* with erect seed vessels, and usually rotate or salver-shaped flowers sixteen in number, are almost all limited to Italy, Greece, and the immediately adjacent regions, except *C. argentea*, which extends as far as Armenia and *C. macrochiza*, a huge, peculiar-flowered species, native of Spain." Besides those just mentioned, there are *C. trichocalycina*, *elatinoidea*, and others, all equally beautiful, and deserving the attention of all hardy plant growers. Other characteristics of the Bellflowers of this region are the abundance of milk and the brittle or succulent character of the plants generally, and also the semi-arborescent habit of a few of them. Although natives of Italy, however, they succeed well on overhanging ledges on the rockery. The sunnier the position the better the result, and during the growing season especially water should be given unsparingly. The following represent those in cultivation at the present time:—

C. ALLIONI.—This is a very rare, although an exceedingly beautiful, dwarf Bellflower. It appears to be grown in most gardens with indifferent success, and is annually becoming scarcer. In Mr. Ewbank's garden in the Isle of Wight, however, it seems to find a congenial home, and not only keeps alive, but increases, and I am told flowers freely. It increases by means of succulent underground stems, and unless plenty of room be provided and fresh soil in which to push its newly-made roots, it will not succeed well, as when restricted as regards space it forms quite a network of roots and soon exhausts the soil. It forms little rosettes of leaves close to the ground, and produces from each stemless flower, resembling both in shape and colour those of the common Canterbury Bell. It should be grown in a light, porous soil free from limestone, and kept continually moist during the growing season. It flowers early in spring, and is a native of Mount Cenis and other parts of Italy.

C. FRAGILIS (Brittle Hairbell).—This is a beautiful little dwarf species, with a very descriptive name, as all who have had anything to do with it know. The stems, and even the leaves, are extremely brittle, and if not carefully handled break like slender pipe-stems. It is a near ally of *C.*

DEIGNED FOR THE GARDEN BY MISS LOWE, at Woodcote, Wimbledon.

HIBISCUS ...

isophylla, from which it differs chiefly in having more slender, slightly ascending, often procumbent stems, smaller ovate lance-shaped stem leaves, and sepals with a prominent midrib twice as long as that of the other. It is also very abundant in milk, and although this is a characteristic of the Order, it is quite a striking feature of this particular species. It is perfectly hardy

Campanula fragilis.

on the rockery, although we invariably lose it on low or flat beds; its thick leathery leaves render it capable of withstanding any amount of drought. Its stems are ascending or procumbent, from 12 inches to 15 inches long: glabrous, or, in the variety hirsuta, hairy, the hairs being the main difference between the two. The lower leaves are set on longish stalks, kidney-shaped, with toothed margins, dark and shiny green. The flowers, which are numerous, are large, open, somewhat bell-shaped, pale blue, and in a rare variety white. It is often used for hanging baskets. It is a native of Naples and Sicily, and flowers with us during the summer months. It is increased by means of cuttings, taken off with a heel or by division of the root. C. Barrelieri is synonymous, or at best only a slight variety.

C. ISOPHYLLA.—This is a charming and profuse flowering species, and, although a native of the sunny shores of Italy, it is quite capable of withstanding the severe cold of our climate. It was introduced to cultivation some few years ago by Mr. Traherne Moggridge, and is figured in his "Flora of Mentone" (tab. 80). It is now pretty widely distributed in English gardens, and makes a most ornamental rock plant. In order to see it to the best advantage, however, it should be planted so as to overhang dry sunny ledges, or else allowed to scramble freely on slopes with a

Campanula Rainieri.

southern exposure. As a hanging basket plant for the greenhouse it is now being extensively used in gardens, and the effect of the two forms, blended as they are seen in the accompanying plate, is in every way excellent. Its flowering season, as indeed that of most of its congeners, extends all through the summer months, and, in the case of indoor plants, much longer. The

stems are often sub-erect, though generally quite procumbent, woody, and perennial. The leaves are roundish, cordate, with crenated margins and set on longish stalks. They are slightly hairy and of a more or less succulent character. The flowers, which are collected into compact terminal heads, are salver-shaped, large and very handsome, lilac or white. This Bellflower is found on a promontory of Caprazoppe, between Noli and Finale, and, as regards distribution, presents a very curious case of restricted area, being found only on a small strip of coast, about two and a half miles in length, between the places just mentioned. "It is difficult," says Mr. Moggridge, "to understand why this Campanula should be so restricted in its area, and the more so as it produces large quantities of seeds, which germinate freely, and are so minute that they could be transported any distance." In cultivation seed is also produced freely, by which means it is readily propagated. It is also increased by means of cuttings taken off about the end of July or August, and placed in a cool pit or frame. It thrives best in a rich open soil, flowering most freely when exposed to full sun; indeed, so freely are the flowers produced under the above conditions, and so fresh does it look all through the summer months, that we consider no garden, however small, should be without it. A synonym of it is C. floribunda.

C. LOREYI (Lorey's Hairbell).—This is also called Pollini's Bellflower in the *Botanical Magazine*, on account of that author having first described it in the "Catalogue of the Verona

Campanula Loreyi.

Garden," in 1812. It is a hardy annual, with a fine graceful habit. It grows from 9 inches to 1 foot in height, and produces large bluish violet blossoms in the greatest profusion. As a hardy annual it well deserves a place in the mixed border, where it should be sown in large masses, as then it shows itself off to much better advantage than in small patches. If allowed to scatter its seeds spontaneously they will germinate, and produce young plants in the autumn, hardy enough, in most cases, to stand the winter, or it may be sown in the open ground along with other annuals in spring. Its flowers, which are large, are blue-violet, and in the variety milky white. The calyx divisions are very narrow, and show themselves between the divisions of the bell (see annexed illustration). The leaves are few, narrow, crenated, or toothed round the edges. It flowers all through the late summer and autumn months. It is a native of Mont Baldi, in Northern Italy, and was first introduced, it is said, by Fischer, when at the Gottingen Botanic Gardens.

C. RAINIERI (Rainer's Bellflower).—The form of this species, represented in the annexed illustration, and the one generally grown in English gardens are, according to our experience, difficult to manage. The ordinary form is very dwarf, the leaves rarely rising an inch above the ground, while the flowers, which are large in proportion, little exceed them. It rarely flowers freely,

although in the open perfectly hardy. The other form attains from 4 inches to 6 inches in height, and forms a cushion which produces a profusion of flowers all through the summer and early autumn. The leaves, as well as the flowers, are much larger than those of the type, the whole plant being more robust, and in all its parts larger. It should be disturbed as little as possible, as it takes a considerable time to recover even when moved carefully. It, however, strikes freely from cuttings. It makes a charming rock plant in a rich, light soil, with plenty of sunlight. It is a native of Northern Italy.

C. VERSICOLOR.—This plant was first figured under this name in Andrews' "Repository"; since then slight forms of it have been described under the names of C. Rosani and Tenori; indeed, under the latter name one often finds this plant in gardens. It varies greatly in the colour of the flowers; in some they are pale blue or lilac; in others darker with an indigo or violet coloured eye; this form is called bicolor in nurseries. It is, without doubt, not even excepting C. pyramidalis, one of the most showy species belonging to this extensive group. On rocky places in Italy it forms a grand sight, clinging, as it does, to the rocks by its thin stringy roots, upholding large masses of stem and leaves together with innumerable flowers. It grows very well in the ordinary border, in which it assumes an upright habit. The stem and leaves resemble those of C. pyramidalis; the latter are thick and leathery in texture, however, and with distinct flowers produced on short stalks. It is little more than biennial, but ripens seeds freely in warm summers. It is a native of Italy, and flowers in July and August.

D. K.

FRUITS UNDER GLASS.

STRAWBERRIES.

WHERE Strawberries in name only are wanted in March and April, one or two batches of plants will now be under treatment, but where Strawberries in reality must be forthcoming, the first week in January is quite early enough to make a start. Preparations for housing must, of course, be put in hand some little time in advance, as I take it for granted that these insect-breeding plants are to be brought forward in pits or Strawberry houses in preference to early vineries and Peach houses. Just now a white frost of unusual duration and severity has got more or less into the surfaces of the balls, and it will not be prudent to attempt top-dressing or cleansing the pots until they are thawed, as the slightest bruise may prove injurious to the crowns. But the plants having been fixed upon, they may be removed to a place from which frost is excluded, and when free they may be dipped in sulphur water and top-dressed ready for placing on the shelves. In modern Strawberry houses the crown of every plant is placed close to the glass, and gentle warmth from the pipes produces a temperature quite high enough to commence with under a free circulation of air, but in these structures even a good ridge of fermenting leaves or short manure is a great help, as it does away with the necessity for constant syringing to counteract the drying influence of the hot-water pipes. In places of this kind 40° should be made the minimum on frosty nights, 45° to 50° when the weather is mild, and 52° to 10° higher may be allowed through the day. No hard-and-fast line must, however, be adhered to, as few plants better repay patience, and none with which I am acquainted so completely collapse under undue haste through the early stages of their growth. The cardinal points to be observed are careful watering with tepid water, as the roots must never be allowed to become dry, gentle syringing on bright, fine days, and a constant circulation of air that will prevent the possibility of the foliage becoming drawn before the plants come into flower. Once the spikes are clear of the leaves and days become longer and lighter, early closing with sun warmth—it is too early to call it heat—will favour their elongation, when the chances will run for rather than against their production of

bold, perfect flowers, followed by a good set of fruit. When very early plants are perched upon lofty shelves in Peach houses, it frequently happens that the flower-scapes stop short and unfold a few flowers close to the crown. Warm diluted liquid from the start may help them, but ammonia from fermenting materials, which feeds the foliage as well as the roots, is the best of all stimulants, and for this reason alone a separate house or pit should always be devoted to them. When forward enough, the Chrysanthemum grower's vigilance should be devoted to the removal of all weak, superfluous flower-buds; the foliage should be pressed down with the hand to let in light and air; and the atmosphere being sweet and buoyant with a little more fire-heat and air, the camel's-hair brush will do the rest. It is not now the time to recommend the best sorts for forcing, as stocks, good, bad, or indifferent, are established in the fruiting pots; but it is more than gratifying to find the craze for endless variety is passing away, and fruit as well as plant growers are paying more attention to well proved sorts which, under good management, can always be depended upon. It is not, however, too late to look ahead, as strong maiden plants, where this important part of culture has been neglected, may still be planted in mild open weather for producing runners next season. It is not, perhaps, the best time, but one of our best Strawberry growers, Mr. Douglas, has said plants may be put out whenever the ground works well; and having myself worked up stocks in a very short time, I can endorse his valuable opinion.

Successions.—From this time forward batches consisting of one or two kinds should be taken in every fortnight. If space is limited, they may be placed in light, shallow pits or frames containing a little latent heat, such, for instance, as exhausted Cucumber or Melon frames, from which the linings have not been removed. The warmth, it is just possible, may be imperceptible, but yet it may be sufficient to give the roots a start. Then, again, there are few country places in which Oak, Beech, or Chestnut leaves cannot be obtained, and gardeners who make the most of everything are well acquainted with their value. These, placed beneath the pots or used outside for linings, in many gardens do one-third of the forcing; but the most complete substitute for a Strawberry house is a sharp-pitched Melon pit with a flow and return pipe running along the front. A pit of these kinds we have just fitted with shelves 16 inches from the glass. Fresh-raked Oak leaves, thrown rather loosely in until they touch the shelves, serve for bottom-heat and moisture, and the plants thrive and fruit admirably in it. When they commence flowering, all the most forward are drawn and placed together at the warmest and driest end, unless we have better accommodation, and when set they are transferred to the hottest structure at command.

Late kinds intended for giving heavy crops in May and shaking hands with early sorts out of doors should now be safely plunged in cold pits, where they are to remain until their work is finished. Space being limited, the plants may be plunged almost close together, when every alternate row can be drawn out for keeping up the supply in the forcing houses; but those intended to ripen their fruit in the pits should not be disturbed, as the moisture contained in the leaves draws out the crock roots during the winter, and, it is needless to say, these are of immense value in the spring. When pot plants are well plunged they do not require much attention with water, particularly where the lights are thrown off every day in mild weather and well tilted when heavy rain is falling; but being so highly sensitive under the damaging influence of drought, mistakes should always be made in favour of exposure and moisture.

THE ORCHARD HOUSE.

Very early trees started in November will now be showing the colour of their flowers, and a tolerably correct opinion can be formed of the way in which they are likely to pass through the most

important, if not the most critical, stage of their culture. If the blossoms are bold, plump, and plentiful, it is reasonable to suppose the roots are satisfactory, and they have not felt the want of water. On the other hand, if only a few are swelling, and the wood buds are pushing forward, the prospect of a full crop of good fruit may be considered the reverse of promising. The first set of trees will now stand a slight rise by day, but no alteration from 45° to 50° must be made through the night, and the syringe may be more freely plied on fine mornings. The second must be coaxed forward by very slow stages, and upon the principle that half a crop, or a late crop, is better than a failure. Meantime, an effort should be made to find out what matter of detail has gone wrong, in order that the loss of a season may not be repeated. If the earliest trees have not been fumigated, two moderate smokings should precede the opening of the first flower. Fly may not be in sight, but it is a subtle enemy which springs up when fumigating would prove fatal, and for this reason this trifling operation should never be neglected. Fermenting material being in favour, this also must be renovated, for, much as Peaches need periods of rest, they always set best in a slightly increased temperature with a nice circulation of air. Fire-heat, of course, will do all that is required, but warmth and moisture playing about the crocks and rising through the branches not only economise, but counteract its drying influence. Moreover, it is now a well known fact that forced fruits of all kinds often suffer through being kept in too dry an atmosphere when the delicate organs of fructification are parched up under its life-shortening influence. Watering through all the early stages, especially during the dark dull months, requires extra care. The water used should be quite equal to the maximum temperature of the house, and whenever a tree is watered it should have enough to thoroughly moisten every particle of soil. A few days may pass before the operation will have to be repeated, but one person should always perform this part of the work, and whilst guarding against making the balls wet and sour, on no account should the roots ever feel the want of water.

Succession houses with a few may be the earliest with many; in either case, the first week in January is a favourable time for making a start, and having the season with instead of dead against Nature all the best mid-season, together with a few whose chief merit is earliness, may be introduced. If the house has been used for Chrysanthemums, I should suggest smoking before the plants are removed, as these and aphids invariably go together. A thorough washing of the glass and woodwork should then precede housing. The trees having been plunged in the open air, they may be free from the larva of insects; but, prevention being better than cure, they should be carefully laid on their sides and well washed with soap and water. The pots also must be well washed, as nothing looks more slovenly than a dirty pot, and examine to see that worms have not been busy amongst the crock roots. If autumnal top-dressing has been neglected, it may now stand over until the trees are in position. Not so the material, as this should be mixed, the better to incorporate the stimulants, some time before it is wanted. Good rotten manure, stiff loam, burnt earth, and bone-dust supply all the trees need until the fruit is set, and this in a dry state cannot be too firmly pressed into the pots. A good watering will then unite the old and new, and the house, after being closed for a week or ten days, may be kept at 45° by night and 50° to 55° through the day; not with closed ventilators and windows, be it understood, but with a nice circulation of air to strengthen the flowers and prevent the wood-buds from getting too forward. Peaches and Nectarines, it may be assumed, will form the chief, if not the entire, occupants; but if it be a mixed collection, Plums and Cherries must have the coolest and most airy quarters. Strawberries, too, may be introduced, provided they can be placed close to the glass, near to the ventilators, and where they can be freely syringed. Cleanli-

ness in the preparation of these must be strictly enforced, and a portion of the rich top-dressing recommended for stone fruits will greatly help them.

PEARS.

Where these are grown in the orchard house none but the best varieties should be introduced, and those principally which do not attain their fullest flavour in the open air in ordinary seasons. If space admits, Williams' Bon Chrétien, Jargonelle, and a host of first-class early and autumn Pears may be grown on until the end of June, when they should be placed out of doors to swell and ripen. But space being available, the amateur may inquire why they are to be turned out. Simply because the chances are ten to one against the fruit being worth eating if they are kept under glass until it is ripe. Those who doubt this theory may convince themselves by comparing fine samples of Bon Chrétien taken from a south wall with medium-sized russet-coated fruit from a pyramid or standard. Indeed, they may test still later sorts, like Marie Louise and Pit-maston Duchesse, by the same rule, and they will find medium-sized fruits from pyramids and espaliers infinitely superior to large, waxy-looking specimens from south walls, especially in hot, roasting seasons. The orchard house under good management ensures a set of fruit and protects it until spring frosts have passed away; but this danger over, the most suitable position is a warm, south border, where, plunged to the rims, well mulched, and liberally watered, the crop will not only be early, but unique in flavour. Passing from the early to the late sorts, one might select a number of varieties which rarely mature their fruit properly in nine-tenths of the gardens north of London, but give them a place in the orchard house, or, better still, a house to themselves, and the quality of the fruit grown would be equal to that of the fine samples imported from the Channel Islands. Take, for instance, Easter Beurré, the old Brown Beurré, Bergamotte d'Espereu, Chaumontel, Passe Colmar, Passe Crassane, and Duchesse d'Angoulême, all of them old varieties, which few of the new ones can surpass in flavour; yet how seldom do the majority of growers find them good enough for the dessert. A good dessert variety is undoubtedly useful for stewing, but knowing that these sorts are capable of standing against all comers when properly ripened, an effort should be made to raise them to their proper position. Other varieties there are which come fairly good in good gardens, but then, sites for half the gardens in the country have been selected for convenience, not for successful culture, and the owners of these might safely include Beurré Diel, Beurré Rance, British Queen, Doyenné du Comice, Josephine de Malines, Madame Millet, Knight's Monarch, Winter Nelis, Thompson's, and the old Glou Moreau. All or nearly all these varieties do well on the Quince, especially when double grafted, and handsome pyramids loaded with blossom buds can be obtained at a very moderate price. Autumn, no doubt, is the best time to pot, but trees of this class can be lifted with balls and potted at any time before the buds burst. The most suitable pots for Pears, which should always be plunged to the rims in the soil, are those now made with perforated sides, and for the following reason, once established in them they can be kept in a fruitful state for years. Being perforated, it is almost impossible to over-water; consequently, whilst giving copious supplies of diluted liquid, the soil never becomes sour and unhealthy. Being perforated, numerous fine roots or rootlets find their way into the friable loam in which the pots are plunged, and although they never produce a gross habit of growth, they force up a never-failing supply of food when the fruit is swelling. The compost for Pears in pots cannot be made too rich; therefore good loam from the red sandstone, old mortar or hair plaster, bone dust, and well rotted cow manure should be thoroughly incorporated some time before the trees are potted. It should be well rammed when dry and watered home, when, the border being ready, the pots may be plunged and mulched for

the season. Although Pears that are thoroughly established will stand a fair amount of forcing, always with plenty of air, newly potted trees should not be subjected to this treatment, as the early growth would be taken out of the system and the crop would be lost. On the contrary, late Pears, like late Plums and Cherries, should have full air throughout the winter and spring, daily protection from cutting draughts when in flower, and gentle fire heat in dark, dull weather to prevent the pollen from becoming pasty or the petals from perishing. When set and past the dropping stage daily syringing and afternoon closing with moderate solar heat will be essential to size, but, the finest quality being the main point, full air must be admitted in hot weather and throughout the autumn months. W. COLEMAN.

Eastnor Castle, Ledbury.

NOTES.

OLD DOUBLE WALLFLOWERS.—One of my earliest of gardening experiences was admiration for the old double Wallflowers, crimson-brown—almost black, indeed, and of rich velvet-like lustre—and yellow, which an old villager in Leicestershire used to grow splendidly years ago. He had served under Wellington at Waterloo, but when I first knew him he was king of the Cabbage family in our locality, growing plots of all sorts of Cabbage plants, &c., for the supply of the local markets, farmers, and cottagers in the neighbourhood. So noted, too, was this old pensioner for his fine Wallflowers, that I never heard him called any other name than that of "Old Gilliver," or now and then "Gilliver" Hubbard, if more than ordinary respect was intended. I long laboured under the erroneous, but pleasing, impression that his toothless old wife was the "Old Mother Hubbard" of the dog and the bone fable. Even when disenchanted by an older boy who jeered me out of my faith, I remember I was none the more happy—indeed, felt all the poorer, although my historical knowledge was undoubtedly improved. Old Hubbard grew his Double Bloody and Golden Drop Gillivers (*i.e.*, Wallflowers in this case) under a sunny old mud wall, and a shilling a dozen was his price for well-rooted young plants. As "T. G." says, the modern double German Wallflowers are coarse and lumpy, and by no means comparable with these ancient cottage garden or English double Wallflowers when well and strongly grown. We have now in flower another double yellow which we call the double Rocket Wallflower, which rarely, if ever, goes out of flower. It has smaller and paler yellow rosettes than the old Golden Drop, and as one flower decays another succeeds it on the same axis, so that each of the little side stalks of the spike produces three or four flowers in succession. On warm, dry soils it flowers very freely in November and December, or later during mild weather.

NEW CHRYSANTHEMUMS.—The Continental growers intend making hay while the sun shines, and one grower alone, viz., M. Simon D'elaux, of Toulouse, has just issued a list of about a hundred new varieties. As a rule, we are now having at least 200 new varieties sent to England every year, and the most difficult point is to determine which of these are really distinct and useful additions, and which are not. No one amateur can afford to throw away his well-tried old favourites and to grow even half of the new sorts which are pulled so extravagantly by their raisers; hence the question arises, what is to be done? As it is, there seems no help, even the much-talked-of Chrysanthemum Society being powerless in questions of this kind. Of course, one can wait until the varieties are grown and shown by the trade growers, and then select only such as are certificated, or such as are seen to be really fine; but

in this way one loses time, and so pays dearly for the knowledge gained. One well-marked sign of the times is that a larger and larger proportion of the Continental seedlings are coming out under English names, so that unless some record be kept, it will be difficult to know the origin of the French kinds. Long ago with Chrysanthemums, as with Roses, a French name, as a rule, meant that the variety so named was a French seedling, but in neither Chrysanthemums nor in Roses does this now hold good. The raiser's name helps us now-a-days more than anything, and deserves careful record—a labour which belongs to the Chrysanthemum Society more than to any other body. As it is, both their catalogue and their medal might be much improved. Only yesterday I asked a friend if he would join the Chrysanthemum Society. "No," he replied; "it has too much of the trade about it for an amateur like myself;" and I am afraid a good many amateurs are of the same opinion.

THE FREESIAS.—Our first little batch of these lovely flowers is now in blossom, that is to say, the earliest buds are expanded, and I am a little puzzled by them. Last year we had only the pale sulphur-tinted variety which came to us as F. Leichtini, and this year all so far have produced white flowers, like those of F. refracta alba. Has anyone else observed Freesias to change their colour from year to year? These bulbous plants are so delicate and beautiful when strongly grown, that the wonder is they are not more often seen. Certainly their flowers are nearly as fragile as they are lovely, but when they are cut and placed in water at once, every bud on the spikes opens out fresh and fair, so that although the individual blossoms are rather short-lived, a spike goes on opening its flowers for a fortnight or longer in a warm room. We have hitherto failed, by growing the bulbs too thickly in the pots, but this year, with six or eight bulbs only in a 6 inch pot, the results are better, the spikes being very strong and branched several times. A little weak manure-water and a little extra heat, just as their flowers appear, help them wonderfully, and they like all the light of this murky season. I wish some one who knows the genus well would tell us how many species or varieties there really are, and what are their distinctions as seen in the garden.

THE BUTCHER'S BROOM.—This is a plant well worth growing in quantity, for its fresh dark green growths, which endure for weeks or even months, if need be, when cut with long stalks and brought indoors. It is by no means a quick-growing shrub, but when planted in quantity in woods and plantations it yields abundant supplies of its dark green sprays. In Italy, and also in the south of France, I am told the peasants cut the tough, flexible stalks of this plant, and utilise them as withies for securing their Vines. One of the finest of all the hardy species of *Ruscus* is *R. racemosus*, which has of some been supposed to be the victor's Laurel of the ancients. It grows well in Devon and in Cornwall, as also in Ireland, yielding glossy Bamboo-like growths, 3 feet to 4 feet long, and these as cut and placed in pots or bronze vases form very lovely ornaments for the house. It is usually called the Alexandrian Laurel, while the larger growing *R. androgynus* is the Greater Alexandrian Laurel, wild in Madeira and the Canary Islands. Our own species (*R. aculeatus*) is the Butcher's Broom, a name suggestive of its former uses, but, plebeian as its name may be, its sprays, when covered with dark red berries, are very beautiful, and endurable to boot.

CHRISTMAS ROSES.—One can withstand a good deal at this festive season, but at p. 580, your

correspondent, "G.," as I think, treats the beautiful *Helleborus atrofolius* a little unfairly. He says, "When pure and unsullied, there is no more lovely flower for the decoration of the hair than this Christmas Rose, and not one in a ball-room would ever suspect its humble origin!" I am sorry that the pretty old custom of wearing flowers in the hair is not now thought fashionable by ladies generally, and I fail to see the point of any suspicion as to the origin of this Christmas Rose. Probably "G.," like many others, yet clings to that old and exploded notion that no hardy flowers are or can be thought so fine as are those of the hothouse! Is not the origin of all plants the same? Are not all plants, whether Austrian Hellebore or Indian Dendrobe, Eucharis of South America or Philippine Phalenopsis, every lovely species in the world, indeed, are they not absolutely wild somewhere or other, and thus is not their natural origin the same? "Humble origin," indeed, as if there could be any real difference of origin between one wild plant and another. Hardy flowers may be different from tropical ones, for the culture of which hothouses are unfortunately necessary in our climate, but each has the same origin, and the question of their beauty is not to be governed by climate, nor by hothouses being essential to their culture here in England. There are a good many amateur gardeners in England to-day who value their Christmas Roses as highly as they do their Orchids or Eucharis flowers, and there are ladies who wear them bravely, or who use them beautifully, without a thought as to their origin, except it be that they are grateful that so much of flower beauty is obtainable from the open-air garden.

THE PATCHOULI PLANT.—All amateurs who are fond of sweet-scented foliage, and possess a warm house or plant-stove, should add a plant of *Pogostemon Patchouli* to their collection. It is a dwarf shrub, with rough leaves somewhat like a *Salvia*, and when crushed slightly in the hand yields a delicious whiff of perfume. It is most pleasant, like Sweet Brier, when a faint whiff catches one unawares, and if its leaves be touched in the morning, its fragrance may be detected throughout the day. A single plant placed near other scented flowers, such as Orchids, Freesias, Roman Hyacinths, &c., gives a tone to them, and adds quite a new charm to their sweetness by half-concealing its source. A Lemon leaf crushed in the hand does the same, and is more generally liked than any other perfume. If the leaf of a Lemon is not handy, then there are two or three plants which may be used as substitutes, viz., the Lemon Grass, the old Lemon-scented Verbena (*Aloysia*), or the leaves of the Citron-scented Blue Gum (*Eucalyptus citriodorus*), or even some of the Lemon-scented Pelargoniums. The true Allspice tree is much liked by some, but is too pungent, so to speak, for many people of keen sense of smell, who find it to be disagreeable. The Patchouli was one of the favourite plants of the late Miss F. J. Hope, of Wardie Lodge, Edinburgh, who alludes to it in her interesting book on "Gardens and Woodlands." VERONICA.

Azaleas planted out.—With reference to Mr. Cornhill's remarks on this subject in THE GARDEN (p. 573) I may state that I only know of one instance in which this plan is regularly practised, and that is at Yeovil, by Mr. Davis. Twelve months ago last autumn when I called upon him he showed me his stock that had been planted out all summer in a specially prepared piece of ground, and no plants could be more satisfactory than they were; they had made good growth, the leaves were abundant and of a dark green colour, and flower-buds had begun to form at every point. The compost consisted of peat and a liberal

sprinkle of sand, and the surface of the bed was a little lower than the surrounding ground. I understood Mr. Davis to say that he had practised the same plan for several years, and that he had better results by it than by keeping the plants in pots. Plants much cut in through furnishing cut flowers make as much progress in one year under the planting out plan as they do in two in pots, and they never fail to yield good crops of flowers annually.—J. C. C.

INDOOR GARDEN.

LEAF MOULD, MANURE WATER AND SULPHURING PLANTS.

ALLOW me to ask you two or three questions respecting matters with which I am unacquainted. (1) What is the best way of making good leaf mould? I have plenty of Oak leaves ready. (2) What is the best manure water for (a) *Cinerarias* (b) *Primulas* (c) *Roses* in pots or planted in a greenhouse? How can one tell about the strength it should be? (3) When sulphur is sprinkled on plants to cure mildew, how long should it remain there before it is washed off?—M., *Eton*.

* * (1) The hard fibry leaves from Oak, Beech, and Spanish Chestnut make the best leaf-mould for potting purposes. Select a quiet secluded spot in your shrubbery, but not too near the hungry devouring roots of old trees, and make a firm square stack of the Oak leaves, of which you say you have plenty. Lay a few sods of turf or branches on the top to prevent disturbance by wind and time will do the rest. Repeat this operation every year and you will have a continuous supply of the best leaf-mould that man can make. If fermentation takes place you may commence using at the end of six months, otherwise the stack will contain the greatest quantity of fertilising matter when a year old. (2) The drainings from farmyard manure heaps, cowsheds, and piggeries cannot be surpassed for horticultural purposes generally, and the plants you name will thrive on it amazingly. If one or all of these sources exist, make an underground tank and conduct all the drainings into it, but guard against the admission of flood or storm water. The tank, it is hardly necessary to say, should be made of bricks laid in cement or well puddled beneath and round the sides to prevent the egress of the liquid and the ingress of spring water; it should also be covered for safety and to keep in the ammonia. Many people defeat the object they have in view by using their stimulants too strong, but your animals being well fed a fair and safe proportion will be one of liquid to six of pure soft water. Try it this strength on a few inferior plants, and if they thrive give it once or twice a week all round. It may be well to put you on your guard against the too free or frequent use of the drainage from stables, the strongest and most dangerous liquid the amateur can take in hand; therefore, this being allowed to mingle with the other, one in eight will be found quite strong enough. We save all the drainings from our houses in air-tight tanks, and use one pint of the liquid to four gallons of water. Excellent liquid can be made by putting one to two pecks of the excrement from sheep or deer into a bag and sinking it into a fifty-gallon cask with the head knocked out. When exhausted and the water becomes colourless, replenish and dilute the first supply, as the great secret of success in the use of all stimulants is bound up in the two words little and often. (3) If sulphur is properly applied to plants, *i.e.* dredged or distributed with the sulphurator evenly over the upper and under sides of the leaves of the plants affected, it will destroy the spores of the fungus in a few hours. Its presence if unobjectionable will, however, do no harm; therefore, your plants being badly affected or the house being subject to mildew it may remain for twenty-four hours or more, when it should be syringed off and repeated at intervals if necessary. But why allow fungoid growths to enervate your plants? Ventilate freely, avoid a cold stagnant atmosphere, do not let your plants suffer from a deficient supply of water at the roots,

and syringe every part of the house occasionally with clear sulphur water. Still following the old adage that prevention is better than cure, dredge dry flowers of sulphur beneath the plant stage, on the pipes, but not on old-fashioned flues, anywhere out of sight, and there let it remain.

Eastnor Castle, Ludbury. W. COLEMAN.

Italian Hyacinths.—Seldom is anything said respecting these for house decoration. I, however, find them to be very useful for that purpose, especially the white and double rose, every bulb of which is sure to throw up two spikes. I decorate the house or conservatory while the first spike lasts, and the second always comes in nicely for cut bloom. My Italians follow close on the heels of the Romans, but the Italians come away together better than the Romans. They have more foliage, but require a little tying up. Of *Scilla sibirica* I grow a goodly quantity, it is so valuable for putting round a short spike or two of either Roman or Italian Hyacinths in small glasses. I could never make any use of it in pots, but, grown in 3 inch pans and planted rather thickly, it throws up a lot of bloom for cutting. Nearly every bulb last year threw up five spikes each. I gathered them weekly just as I wanted them. Mine are now beginning to push up some odd spikes. Some Hyacinths, such as Robert Steiger, whose foliage is curled outwards, are much more elegant for rooms than stiff, upright-leaved ones.—WEST HALL.

The genus *Hovea*—This is an old and much-neglected genus, consisting of beautiful greenhouse shrubs, the flowers of which are, in nearly every instance, blue or purple. They are plants of rather straggling habit, which the cultivator must rectify by constant finger-and-thumb pinching during the growing season in order to induce the production of laterals, and thus lay the foundation of a bushy plant. The best soil for *Hoveas* is a compost consisting of three parts peat, one part light loam, and a fair proportion of sand. As in the case of all other hard-wooded plants, the drainage must be effective. Amongst species the following are the most showy: *H. Celsi* is a free-growing plant, which requires much attention in order to induce it to form a handsome bush; its beauty, however, well repays any amount of labour that may be necessary to accomplish this end. Its leaves, which are alternate, are very deep green on the upper side, but paler below. The flowers, which are pea-shaped, are of a beautiful blue colour, with the exception of a white spot at the base of the standard. A well-managed specimen of this plant is a grand object, either on the exhibition table or in the greenhouse, and its flowers last long in beauty. They are produced in April, May, and June. *H. pungens* is a more twizy species than *Celsi*, but not less beautiful. The leaves, which are linear, are furnished with numerous large, bristle-shaped stipules at the base. The flowers are axillary; the standard rich blue, shaded with violet, and there is a white spot at the base. The wings are brownish purple. It blooms during May and June. *H. purpurea* is a robust-growing plant with downy stems. The leaves, which are alternate, are ovate-lanceolate, about 1½ inches long, dark green above, clothed beneath with a light, brownish-coloured down. The flowers, which are axillary, are numerous; the standard is purple, and the wings are tinged with brown. It blooms during May and June. *H. villosa*, which is nearly allied to the preceding, has shaggy leaves on the stems and branches. The leaves, which are alternate, are linear, dark green above, and clothed on the reverse side with a dense covering of long, shaggy hairs. The flowers, which are axillary, are lilac-coloured. It blooms during April and May.—W. H. G.

Canary Islands. The writer (a botanist) purposes spending February at Tenerife and Grand Canary, and will be glad of any information as to the habitats of rare plants in these islands. Webb and Berthelot's "Flora" is now fifty years old and probably very imperfect, but there may be more recent lists of plants scattered through botanic periodicals. Should any such exist, the writer will be glad to know where they are to be found.—F.

THE GREAT SNOWSTORM.

THIS year Christmas departed after all with a crown of hoar-frost on its head. Sunday opened with fitful showers that collected their forces into a steady downpour of rain throughout the afternoon and evening. Between seven and eight o'clock the rain crystallised into soft, floppy flakes of snow, which hardened into greater dryness as the scarcely perceptible and silent east wind dried them as they fell. The snow, however, fell on a wet, sloppy base as it succeeded the rain without any interval. Neither was there any perceptible or audible wind. The snow fell heavily in huge flakes on a still earth out of a heavily laden sky, and it fell so fast, that about ten o'clock it lay on branch and bough and over the rain-soaked ground to a depth of about 6 inches. And still it snowed and snowed faster and more persistent, and in larger, heavier flakes than ever. Soon after midnight the wind arose, and it blew during the night with such force, as to drift the heavy and soft snow into large drifts a yard or more in depth. The wind also proved the salvation of many a tree and shrub—for though in many cases it failed to dislodge the snow, which hugged them closer and closer the more it grew in weight, and in consequent destructive force, yet the wind, which reached a full half gale at times, did shake off the crushing weight from not a few trees in exposed positions, and thus saved them from the impending destruction that overtook many others that failed to get rid of their sudden and crushing burden. In the morning the snow in the open reached a thickness of 10 inches. It was then thawing rapidly as well on the surface as at the base; so it is safe to reckon that at least a foot of snow fell here—an almost unprecedented fall in the time. Nor does the mere thickness of the snow exactly measure its destructive force, for there is a great difference between the weight of snow of differing characters. Frozen flakes seem light as feathers, as well as to resemble them in other qualities; but sloppy snow, compared to these, may almost be said, without hyperbole, to be as heavy as lead; and hence possibly the snow on the evening of the 26th and early morning of the 27th may probably be found amongst the most destructive that has ever occurred to trees and shrubs. The disfigurements of both are the most marked features in the garden and pleasure grounds; but in the park it has dealt some very destructive blows to the Cedars of Lebanon. A good many boughs are also snapped off various Conifers in the pinetum. Most of these are snapped straight across, as if they might have been rods of glass. Not a few branches of deciduous trees and shrubs are also broken off sharp across, as if they had been sawn off; and a very curious example of the force of the snow on deciduous shrubs is furnished by a tall Lilac, which is borne right down and torn up by the roots through the sheer weight of the snow on its leafless top.—D. T. FISHER, *Bury St. Edmunds*.

— We have sustained much damage from the snowstorm, which has been very destructive. Trees of every size, shape, and species are broken down, twisted, and in some instances quite dragged out of the ground by the roots through the weight of the snow. Several of our great Cedars have large limbs broken off. An old tree of *Pinus Mugho* is broken right in half; few trees indeed seem to have wholly escaped, but evergreen species have suffered the most; in almost every case they are quite weighed down to the ground with snow or broken off. I fear it will be a long time before we recover from the damage done in so few hours. Yesterday (December 26) it was raining most of the day, but towards six o'clock it commenced snowing, and kept on until daybreak this morning. The snow is fully 7 inches deep and of a very heavy character.—W. HOLMAN, *Redleaf, Panshurst*.

— The early part of Sunday (Dec. 26) was almost incessant rain, followed, about half-past three in the afternoon, by snow, which continued to fall till late in the night, by which time there were between 1 foot and 2 feet of snow on the ground; and, owing to its being very soft, it ad-

hered to the branches of trees and shrubs, so as to be early in the evening quite dangerous to pass beneath trees of any kind. In the morning it was deplorable to see Elms, Oaks, Birch, and many other forest trees sadly broken in the park, and many uprooted. Laurels, Rhododendrons, Yews, &c., were bent to the ground; some were uprooted; but the destruction did not end with timber trees. On visiting the pleasure grounds the sight was truly alarming. Several handsome old Scotch Firs situated here were almost wrecked, as were also some evergreen Oaks situated near them; large limbs were broken down to the ground, and others were split by the weight of the snow, coupled with the high easterly wind which accompanied it. Several Cedars of Lebanon situated in the garden and in the park adjoining were sadly disfigured, many large limbs being torn off at the base, and many smaller ones split, thus disfiguring them for a very long time to come, if indeed they ever perfectly recover.—C. WARDEN, *Clarendon Gardens, Wilts.*

— One of the heaviest and most violent snow-storms which we have experienced for some years occurred on Sunday afternoon and evening last. A cold, sleety rain had been falling all the morning. At three o'clock snow began to fall, and the wind rose to a regular gusty gale and continued to do so until past midnight, at which time the snow also ceased to fall. Fortunately, the cold was not severe—the thermometer did not fall below 31 at any time during the night. The morning revealed sad destruction amongst trees and shrubs, especially Evergreens. Young Conifers were lying flat on the ground, and huge branches of Cedars had been broken off by the weight of the snow. Pyramidal-shaped trees suffered least, Wellingtonias having scarcely a branch injured. Laurels, Hollies, Sweet Bays, and Arbutuses have suffered a good deal. It is difficult to measure the depth of snow, owing to the drift, but I think 8 inches may be set down as a good average.—TARNTON, *Somersetshire.*

— The snowstorm of Sunday night did us grievous damage: the snow was of that sticky kind that holds on and loads the tree. We saw it coming on at dusk and feared greatly. About nine o'clock it was heartrending to hear the poor trees breaking in all directions; outside of human troubles this is one of the most piteous things I know, and of an interest almost human. It is like seeing people drown and unable to give help. Next day saw dreadful wrecks among the poor Scotch Firs, many absolutely done for, and hardly any without more or less of mutilation.—J., *Swrby.*

— After a pouring wet morning snow began to fall here on Sunday at 5 p.m., and increased so rapidly that the ground was soon covered. At 10 p.m. it was 6 inches in depth, and the storm continued in full force till midnight. The average depth to-day (the 27th) is 14 inches, and everything presents a very wintry appearance. I never saw such havoc wrought amongst Conifers as has been wrought on this occasion. One of the handsomest Cedars in North Bucks, which has adorned the grounds here for many a year, has been wrecked, and a grand old Stone Pine in the rectory grounds, which had been braced together to preserve it, has lost two of its best limbs. Bays, Laurels, Junipers, and all kinds of Evergreens have also been more or less injured.—G. BLOXHAM, *Buckhill, Blotchly, Bucks.*

QUESTIONS.

5540. **Woodlice on fruit.**—Can some reader of THE GARDEN suggest anything to prevent woodlice and other insects injuring fruit which stored away in a cellar? Chase's Beetle Poison is of no use for that purpose.—R.

5541. **Moss on lawns.**—My lawn has got covered with Moss. Would ashes or bones put on it destroy the Moss? and what time of year is the best to attack it? There are great quantities of flower roots planted on the lawn, and I do not wish these destroyed.—W. M. D.

5542. **Christmas Roses.**—Can "O." (p. 586) afford any proof of his statement that cross-bred Helleborus have ever been raised between *H. orientalis* (Lenten Rose) and *H. niger* (Christmas Rose)? I have repeatedly tried this and similar crossings, but could obtain no result, and I know of at least

two other growers who assure me that in no case could they obtain crosses between the two sections of the genus Helleborus. *H. guttatus*, *H. atro-rubens*, and *H. orientalis* inter-cross freely, and we have many seedlings now coming into flower.—F. W. B.

TREES AND SHRUBS.

UNSIGHTLY ARAUCARIAS.

PERSONS often seek information as to the best means of restoring to health diseased and consequently unsightly specimens of *Araucaria imbricata*. The cause of this now too common malady is imperfectly understood, and the best means of coping with the disease is consequently just as imperfect. Having had a rather wide practice amongst trees, I may be allowed shortly to state my opinion of the evil, as well as suggest means of restoration that have been found of great avail, in numerous cases at least. The first and principal cause of the *Araucaria* so frequently turning unhealthy in our gardens and grounds is due to planting in unsuitable soils and under the shade and drip of other trees. Far too frequently it happens that in planting the *Araucaria* little or no attention is paid to the soil in which it is placed. A hole is dug, a barrowful of what is termed good soil placed in it, and the tree planted; and, what is as bad, if not, indeed, worse, a wrong impression that the *Araucaria* requires coddling and shade, causing it to be placed in too close contiguity to other trees. If you want to plant an *Araucaria* that will reflect credit on the planter in years to come, choose, first of all, an open spot away from all trees and big growing shrubs, and if the soil is not of a free, rich nature, and perfectly unsaturated with excessive moisture, make it so by, first of all, thorough drainage, and, secondly, by substituting an open sandy loam for whatever the objectionable soil may be. Travel where you will throughout the country, meagre-looking *Araucarias*, with half of their branches dead and dying, frequently confront one. The cottager must have his *Araucaria*, although attached to his house there is not more than a couple of square yards of available space; and, indeed, town-folk are but little behind in this matter, for, whatever else adorns their miniature garden, the *Araucaria* must be first on the list, the position or suitability of the soil being in most cases of only secondary consideration. I have just examined about half-a-hundred specimens of the *Araucaria*, and find that where an open situation and free, well-drained soil is present the *Araucaria* does well, but let the ground be stiff, plastic, and excessively damp, and the tree planted beneath the shade of others, then the disease and its consequent unsightly appearance in the foliage is sure to follow. By far the finest *Araucarias* I know of are growing in a disused gravel-pit, the holes in which they were planted being dug large and wide, and having a couple of cartloads each of road-scrappings and decayed vegetable refuse intermingled with the rather roughish gravel. They have been planted upwards of forty years, and to see them in the perfection of health, with wide-spreading branches and lofty heads, does the tree lover good, and forcibly reminds him that, circumstances being equal, the Emerald Isle is better suited for certain species of Conifera than any other part of our country. In the woodlands of this estate the *Araucaria* does only middling when mixed up with the general run of our forest trees, for if in the least crowded, the lower branches assume a brown and diseased appearance, and the whole tree lacks the rich, healthy tone that is so characteristic of it when grown under favourable circumstances. We have been thinning an old Oak wood in which, owing to the wide distances apart at which these trees stood, a number of the Douglas Spruce, Weymouth and Cembra Pines, Lebanon Cedars, and the *Araucaria* were planted, more, perhaps, for ornament than under the supposition that they would ever become a remunerative crop. Excepting the *Araucaria*, all the other trees have done well, for the soil was a kindly, friable loam, which rested at no great depth on a shale rock, and the situation well sheltered and warm. Wherever the *Araucarias* were overtopped by the Oak branches there signs of ill-health are apparent, although where open and exposed they look well. *Penrhyn.*

Weir's Cut-leaved Silver Maple.—Mr. Ellwanger says that, though but little known, this is one of the most beautiful and remarkable trees with cut or dissected foliage yet introduced. Its growth is rapid, shoots slender and drooping, giving it a habit almost as graceful as the Cut-leaved Birch. The foliage is abundant, silvery underneath, and on the young wood especially, deeply and delicately cut. The leaf-stalks are long and tinted, with red on the upper surface. We believe it will rank at once among the most interesting and attractive of lawn trees, and may be easily adapted to small places by an occasional cutting back, which it will bear to any degree necessary as well as a Willow. It will doubtless eventually become vastly more popular than the Birch, owing to the ease with which it may be propagated. It grafts or buds readily on seedlings of the Soft Maple. A favourite way of working it is to bud or graft it at a standard height on the strongest growing seedlings; this plan adds greatly to its pendulous habit.

The Weeping Ash should not be forgotten by planters. It is a well known weeping tree of vigorous habit, its branches spreading, at first horizontally, but gradually drooping towards the ground. Its strong, stiff growth does not render it as graceful and ornamental as many of the trees of this class, but planted singly on a large lawn it forms an interesting object. It is one of the best trees for forming an arbour. *Fraxinus excelsior pendula* is a variety of the preceding, but scarcely quite so strong growing, and it is characterised by the yellowish bark of the young branches which gives the tree a peculiar appearance. *F. lentiscifolia pendula* is a pendulous variety of the Lentiscus-leaved Ash, and forms a fine ornament in a sheltered situation. It requires to be grafted some 6 feet in height, in order to show off its true character to advantage, as its branches are very slender and Willow-like compared with those of *F. excelsior*. They are, however, produced in great abundance, this variety of Ash making an excellent pendulous umbrella-headed tree.

Darwin's Barberry in wet soils.—Few know how well the beautiful *Berberis Darwini* thrives in drained bog soil. It does well in most soils, but seldom have I seen it equal to a few plants of it which we have here in a bog soil, where it makes finely branched shoots from 8 to 10 feet long in one season; and when in spring these are smothered with bloom, and surrounded by masses of Rhododendrons in all shades of colour, from white to a deep crimson, the contrast is most pleasing; the colour is so rich and telling, so entirely its own, that there seems nothing wanting to make the picture perfect. It should be planted well back or it is liable to bury things behind it of dwarfer growth; and do not forget after it has done blooming to head it well in. It makes, too, here and there grand isolated specimens. I hope this account of it will induce others who have bogs to plant it largely. It seems to thrive even where the Rhododendron looks sickly through too much wet and hard frost during winter. Why not also miles of hedging planted with it? It is both handsome and effective, and, on account of its spines, quite equal in the way of defence to Thorn or Quirk, which do not do well in bog.—T.

The Copper Beech in Hampshire.—This tree is still unvalued in the contrast it presents to the eye in the landscape, but there appears to be a difficulty in the grouping of it, so as to give sufficient effect to the contrast. Most specimens I have seen are evidently in the wrong place for this purpose. It is plentiful throughout this county, as there are very few lawns or pleasure grounds without a specimen of the Copper Beech. A departure from the ordinary routine in planting it was made some few years ago at Brookwood, by Colonels William and George Greenwood, who planted a line of them on either side of the road from Winchester to Petersfield, commencing at Woodcote and extending eastward for nearly a mile and a half; but as I have not seen them for some time I forbear giving a description at present. The finest specimen I have to record is in the rectory grounds near the house at Over Wallop, about three miles south of Gabley Railway Station; it has the large circumference of 9 feet 1 inches, and has otherwise attained the dimensions

A. D. W.

of a large tree, but unfortunately my notes give no further dimensions. Soil, clay on the chalk. Measured in 1880. There is another tree in Amport pleasure grounds, near Andover, which is a good specimen, with a girth of 6 feet 8 inches. Soil, clay on the chalk. Measured in 1880. There is a third at Boanbridge House, near Winchester. This has assumed a beautiful weeping habit, and stands alone on the lawn in front of the house. It has a fine effect, and is almost the only one I have seen rightly placed. It has a circumference of 6 feet 1½ inches. Soil, alluvial; subsoil, plastic clay. Measured in 1880.—R. S. J.

THE ORIENTAL PLANE IN GREECE.

The Oriental Plane attains to a very large size and to a great age, and more especially so in the eastern parts of Europe, where there are many and numerous instances. A very noble example may be seen growing in the village of Vostiza, in Greece, on the Gulf of Lepanto, which girthed (when I was there in 1842), at 5 feet from the ground, 37 feet 4 inches. I had visited and measured this same tree six years previously, viz., in April, 1836, when I made the girth to be exactly 37 feet at the same height. Whether in the six years it could have increased in growth 4 inches I could hardly venture to say—the difference of measurement might possibly have arisen from some excrescence on the bark unnoticed at the time, but, be it as it may, the measurements both times were carefully made with a tape line.

This tree, situated in the middle of the village, on a gradual slope, standing on a raised platform of flat stones, evidently for protection to the roots, is a striking object on entering the village, and especially noteworthy, as existing in the days of Pausanias, the Greek historian, who, living in the second century, makes mention of it in his travels (see Burgess' "Greece"), and the tree must have been of considerable size and age at that time to have made it worthy of remark, its age probably dating considerably before the Christian era, making it more than two thousand years old, and yet, when last seen by me in 1842, it was in full vigour and health, the trunk, apparently, for some way up, perfectly sound, though many of its larger limbs and branches had succumbed to age and storm. I had no means of measuring its height, but at a rough guess I should say it could not have been less than from 130 feet to 140 feet, or perhaps more.

Should this meet the eye of any of your readers who may have travelled in that part of Greece, and have noticed this tree in more recent years, or any who may hereafter visit it, and were they to record their observations as to its state and appearance at the present day, should it be still standing, which, unless it may have met with some untoward accident from the elements, I have every reason to hope it does, being much revered by the inhabitants, notes on the subject would be of the highest value. There are many other parts of Greece and also Turkey in which I have noticed the Oriental Plane of remarkable size and beauty, but I will only mention one or two places, and one of the more notable of these is along the banks of the stream running through the vale of Tempe into the plains of Thessaly at the foot of the Olympian range, where many magnificent and stately specimens fringed its banks for many miles, and were growing in the greatest luxuriance, when visited by me in 1846.

The Oriental Plane seems naturally to luxuriate on the banks of streams, and I was especially struck with the magnificence of a grove of these trees in the island of Crete, where, in a vale at the foot of the white mountains in Sfakia, a few hours' ride from the town of Khania, watered by a copious stream, and probably getting its name Platanus, as well as giving it to the whole vale, from the number of trees of this species growing there, the beauty of which is much enhanced by many of the largest and finest trees being held firmly in the grip of gigantic vines entwining their trunks for some feet above ground, as it were, with a huge cable nearly the thickness of a man's body, and afterwards stretching out in long rope-like folds, through and over the branches to their very tops, and hanging down in long pendent

festoons of bright leaves and fruit, and yet the trees seemed in good health, though they must have been held for many a long year in the grasp of these monsters. While on the subject of these trees, I may here remark, for the benefit of those who may be ignorant of the fact that there still exists in the island of Crete, or did so some few years ago, an evergreen variety of Plane tree, mentioned by Pliny and others, and authenticated by Admiral Spratt, whom I had the pleasure to accompany in one of his numerous visits to the island, but, though near the spot with him, he had not then re-discovered this rare and possibly very local production of Nature.

KITCHEN GARDEN.

CHICORY AND MUSTARD AND CRESS.

WITH plenty of these no one need care much whether they have many good Lettuces and Endive at mid-winter or not, as with Chicory and Mustard and Cress, salads of the very highest quality may be made, and they can be easily grown in quantity, let the weather be what it may. Witloof was introduced some years ago as an improvement on Chicory, but I have not found it to be so, and have, therefore, ceased to grow it. Chicory is hardy, grows freely, and when forced produces a large quantity of delicate leaves. The seed should be sown annually in May in rows thinly, and the young plants soon produce Salsafy-like roots without much attention. These are taken up in November, placed almost as close as they will stand in 8-inch or 10-inch pots with some ordinary soil round them, and they are then ready for forcing. We wheel a few barrow loads of fermenting material into a dark shed, plunge a few pots in this, and in a fortnight or little more the roots throw up a tall cluster of cream-coloured leaves of the finest salad-making quality possible. A few potfuls are introduced into heat now and then, and in this way there is no difficulty in keeping up a constant succession. When wanted for use the crowns are cut right through, and if the latter be kept in heat after that, they will push out side-growths which will come in for use afterwards. Chicory may also be forced under a stage in a warm pit, and where no other means of keeping it in the dark exist, another pot, of the same size as the one it is in, may be turned upside down over it. Mustard and Cress, as we all know, are easily grown. Some time ago I found a patch in the shallow boxes, which we use for producing them in winter, die away here and there prematurely, and on making an examination to ascertain the cause, I found that some parts of the soil were very firm and others were loose, and it was in the latter the plants had failed. After that I ceased to use old soil of any kind to fill the boxes, and substituted leaf-soil, making it very firm all over. I sowed the seed on the surface, and did not cover it in any way, finally placing it in a temperature of 60 degrees. Here growth was rapid, and in ten days each box was an even mass of beautiful green Mustard and Cress. In leaf-soil it grows uncommonly well—better, indeed, than in anything else we have tried, and uniform firmness retains the whole in excellent condition. Our winter Mustard and Cress boxes are those which we use for bedding plants in spring. They are 3 inches deep, 1 foot wide, and 2 feet 6 inches long. By sowing from two to four of these weekly, a regular and plentiful supply is kept up, and if frost chances to catch Lettuces or Endive, they are not much missed.

J. MUIR.

The best Potatoes.—The suggestion made by "E. B." (p. 573) that readers of THE GARDEN should give the names of the sorts of Potatoes which they find to be of good table quality in different soils is an admirable one. There are some who disbelieve that soil has any influence on the quality of Potatoes, but that is not my opinion. I have given all the American sorts a fair trial, but none of them are to be relied upon. In a dry summer Early Rose and Beauty of Hebron are fairly good, but never first rate. I should mention that our soil is cold and heavy, and that it gets

more manure than is good for Potatoes. Nevertheless, the old Ashleaf, Myatt's Ashleaf, Covent Garden and Porter's Excelsior are to be depended upon. Magnum Bonum and Scotch Regent are also good. But such sorts as White Elephant, Cosmopolitan, and Woodstock Kidney are very inferior as regards eating quality, although excellent croppers. The old Fortyfold was grown by numbers of cottagers in this district last year, and produced excellent crops. As many of your readers doubtless know, there is no better eating Potato grown than this. But it is only suitable for rich land, and is very very liable to become diseased. I am surprised that Covent Garden Perfection has not become more popular than it is. It is a capital cropper and second to none as regard eating qualities.—J. C. C.

CELERY IN WINTER.

IN many gardens, especially small ones, Celery is the only salad plant to be found in winter, and, apart from its value in this way, it is also most acceptable as a culinary vegetable. No labour should therefore be spared to make the supply of it as plentiful and good as possible, but Celery which might be in prime condition in August and September will not be of much value now, as it becomes soft in the centre and not so crisp and firm as when it is approaching full size. The best Celery for winter use is that which is now only about three parts grown, and spring Celery need not be more than half grown at the present time. The winter Celery crop should extend from November until March. Its most injurious enemies are damp and frost. Deep trenches on each side of the plants will help greatly to drain off superfluous moisture from them, and where there are only one or two rows together a good bank of soil put against them (as is done in earthing up) will prevent a great deal of rain from reaching the plants, as it will fall on the sides and run off. A quantity of finely sifted ashes if placed round the plants at the last earthing up will prevent them to a great extent from decay, as the ashes do not cling to the leaves like sticky soil. All earthing up of winter Celery should be completed as soon as possible, and it is most important that the soil be prevented from falling into the centres of the plants. This is injurious at all times, but more particularly now, as damp earth will cause the interior of the plants to quickly decay. If each plant is tied up firmly with a piece of matting before earthing, and it is afterwards removed, earthing up will be more easily and safely done than when untied. I do not approve of lifting a large quantity of Celery and keeping it stored away for use. This plan is convenient if practised before a protracted frost sets in, but it does not possess any other advantage. The plants should be well protected in the trenches at such times, and this may be done by putting a good band of hay or straw round each, but it is not safe to allow this to remain on when there is no frost, as it may cause the plants to perish from damp. Timely protection is the secret of successful preservation; there is little or no use in covering them up after the leaves have been almost reduced to a pulp by frost.

J. MUIR.

Margam.

New flower cups.—Anyone who has had experience of flower shows where cut flowers are exhibited cannot fail to have noticed the want of harmony or symmetry that is often seen on the stands of competing flowers. In some schedules of prizes it is required that the stands or boards on which the flowers, such as Dahlias, Chrysanthemums, Asters, Roses, &c., are staged should be of uniform size and colour; but when this is the case the flowers are set in them at different levels of elevation, and the whole has an irregular and confused appearance, distasteful to the eye. To obviate this, Mr. Benjamin Field, of Swan Place, Old Kent Road, has brought out what he terms his Jubilee Flower Cups, for exhibiting cut flowers in, and more especially for Chrysanthemums. The cup which contains the flower is made in three sizes, for large, medium-sized, and small blooms; the widest are 3 inches, the smallest 2 inches, and they fit into the water-tube in a telescopic manner, so that the flower can be raised at any

desired height from the board. The tube, which has the cup at the top of it, has an inner tube of a smaller size, for the stem of the flower to fit into, and there is a wire loop at top and bottom to keep it secure. They are made of zinc, are nicely finished off, and will last a long time. A lady said, in our hearing, when she had examined the tubes: "What excellent things they are for placing in glass and other vases to keep flowers in an upright position for the decoration of a sitting-room," and this appears to be an end these tubes are well calculated to serve.—R. D.

PEARS AND THEIR HISTORY.*

I HAVE been asked to give some account of what I know about Pears. There is, of course, much to be said about a fruit which more than any other attracts the attention of the cultivated pomologist from the extraordinary development it has attained in our own time, the ancients having been contented with fruit certainly unequal in flavour to that which we enjoy. M. André Leroy, in his dictionary of pomology, has taken the trouble to make very learned researches regarding antique Pears, and enumerates four Greek and thirty-five sorts of ancient Rome; but he does not fix the time when these ceased to be catalogued, and gives only twelve sorts of Italian Pears between the fifteenth and sixteenth centuries, the varieties cultivated in France from Charlemagne to Louis XIII. numbering 260 kinds. Pliny names twenty kinds. Varro, Palladius, Cato, Columella, and Virgil are also pomologists and Pear lovers. The latter is very urgent in the matter of grafting Pears, but seems to have been aware of the modern axiom that "he who plants Pears, plants for his heirs."

In 1665, John Rea published the "Flora, Ceres, and Pomona," in which he gives a list of twenty-one Pears, described as being very good, one of them rejoicing in the extraordinary name of Dead Man's Pear. He describes the Winter Bon Chrétien as one of the most excellent, but requiring to be grafted on the Quince stock and trained to a wall. He also says, "that there are several good sorts of Wardens and baking Pears." In 1693 John Evelyn published a translation of the works of Monsieur de la Quintinye, a very voluminous, exact, and twaddling French author. In advising the setting out of a plantation of dwarf Pear trees, he begins with the choice of a dwarf tree to be planted alone—*Le*, the Winter Bon Chrétien, giving several reasons for this preference. "1. Because of its antiquity, and that by its singular excellence it gained the admiration and courtship of the world, the great monarchies, and principally that of old Rome having known and cultivated it under the name of Crustumium. 2. It was baptised at the very birth of Christianity itself, and consequently it should have the veneration of all Christian gardeners. 3. It should be considered of itself and with respect only to its own proper merit, which alone can entitle it to a preference." This is, at all events, a very proper decision to arrive at, but the Winter Bon Chrétien has not kept the high rank assigned to it. De la Quintinye indulges in the most extravagant expressions of esteem: "That it grows to the weight of 2 lbs., that it is considered a handsome present to persons of quality, and that it is a Pear the beauty of which has caused the ablest gardeners to labour for it with the greatest passion." I have had a good experience of Pears, but I have never known this precious Pear except by name, but it may have degenerated, or we of the present time are more particular in our tastes. Of the other varieties named by Mons. de la Quintinye, the Autumn Bergamot, the St. Germain, the Colmar, and Crassane have survived to our own time, but without holding rank as first-class fruit; he, however, highly commends the Beurré Rouge, classing this as a synonym of the B. d'Amboise and Isambert, which he says "possesses the first degree of goodness—*viz.*, a smooth, delicious softness with a fine delicate pulp," wasting many good epithets on the Winter Bon Chrétien which would have been more properly applied to the Beurré Rouge. The Autumn Bergamot is not highly commended, although our friend says, "that it has a numerous and formidable party, and, indeed, that a thousand people assert that for its tender and melting pulp, its sweet and sugary juice, and the little smack of perfume which

accompanies it, that is more valuable than all other Pears in general," remarks which a great many ignorant people make at the present day. De la Quintinye names some ninety or hundred sorts of which some of the names are expressive, as Greedy Guts, Chew Good, Daughter of God, or Fille Dieu. Some few of the sorts remain, among them the Rousselets, Chaumontel, and St. Lezin. De la Quintinye's reasons for the enjoyment of Pears are curious. He states that "the rigorous cold which lasts from November to March enjoins our placing ourselves near the fire, and that to counteract the external foreign heat then taken in, Nature has provided us with Pears to prevent the great infirmities which might happen to us from the enjoyment of so much heat. So precisely at this time she has given us an admirable quantity of tender fruit such as Bergamots, Louise Bonnes, Les Chasseries, Amberts, Virgonlees, Epines, and St. Augustines." This garrulous author provides for the plantation of a thousand trees, but states that "the planter of so many would be a curious gentleman, for how could he dispose of 12,000 Pears unless he gave them away or made perry of them?" This difficulty would not be felt now. He concludes his remarks on Pears by a list of fifty good, forty-four indifferent, and sixty-six bad sorts.

In 1729 Batty Langley, in the "Pomona," gives the names of fifty-seven Pears. Those which are named by him and still cultivated are the Brown Beurré, Autumn Bergamot, Hamplen's ditto, Crassane, Epine d'Hiver, Jargonelle, Swan's Egg, and Windsor, and among baking Pears the Black Pear of Worcester and Catillac. Mr. Langley is not enthusiastic about Pears.

Switzer enumerates eighty Pears, advising the planting of the English Bergamot, "because of its goodness and antiquity, it being not impossible that it has been an inhabitant of this island ever since Julius Cesar conquered it, and that possibly it was the Assyrian Pear of Virgil, and was, as may be deduced from this, a part of the celebrated Gardens of Alcivous." A tree of this sort in the Sawbridge-worth Nurseries is said to be 300 years old. The Pears selected by Switzer appear certainly to have been the best of that time, and he testifies to the extreme goodness of the Winter Bon Chrétien.

Philip Miller, in his "Gardeners' Dictionary," 1759, begins his list with Petit Muscat, and passes on to the Chio, Citron des Carmes, La Bellissime, bearing two crops in July and September, Jargonelle, and Cuisse Madame. The Cuisse Madame of the French is classed as a good Pear, and the Jargonelle as third rate; but Mons. Leroy describes the Cuisse Madame as a small inferior Pear, ripening about the end of August, considering it as one of the few historical Greek Pears which have come down to us. The Poire d'Épargne or Jargonelle of André Leroy does not correspond with the outline of our Jargonelle, and he does not praise the fruit, calling it good only for the season. Our true English Jargonelle when ripened on a wall is exceedingly good, juicy, and refreshing. Probably the spurious Jargonelle, which undoubtedly exists, has been introduced by those who have imported this sort from France, having been misled by the name, not being aware that the Jargonelle of the French nurseries is not the kind which passes under that name with us. Leroy says that Miller has muddled the Jargonelle, and that the confusion caused by him has lasted to our own time, the mischief arising from the Jargonelle and Cuisse Madame being classed by Mills as synonymous.

Miller names eighty sorts, and states that he has included in his list many sorts that are not worth planting to please those who are fond of a great variety. He is aware of the eccentricity of the ripening period of Pears, for he says, "I have known the fruit of a Pear tree in one year all ripe and gone by the middle of October, and the very next year the fruit has not been fit to eat until the very middle of December." All of us can endorse Miller's remarks. I have found it a very difficult matter to fix the date of ripening, and the variations noticed in 1759 find their equivalent in 1886. In reference to this matter, Miller says that "if we look back to the best French authors of fifty years ago, they put down the times of ripening of Pears a month or six weeks later than

now, and that in London it is much about the same, the time of ripening in London being quite as forward as Paris." This remark does not seem to indicate that the climate is becoming colder, as many are inclined to think. There are many writers on pomology after Philip Miller, but as far as the names of Pears are concerned we may step from 1759 to 1831, when a book was published by George Lindley and edited by Dr. Lindley, entitled "A Guide to the Orchard and Kitchen Garden." The list of Pears is here brought down nearly to our own time, 150 dessert Pears being enumerated, among them many of our old friends of 1665, 1693, 1729, 1731, and 1789, and adding to the list a number of new sorts raised from seed by Van Mons, Nelis, and others. According to Lindley many of these are not worth much, the Duchesse d'Angoulême and Beurré Diel being credited with special praise, the Marie Louise, however, not being very highly commended. In 1842 the Royal Horticultural Society published a list of 412 sorts, and Dr. Hogg, in the fifth edition of the "Fruit Manual," 1884, describes 732 sorts. André Leroy, in the "Dictionary of Pomology," has 915 sorts, and the cry is, "Still they come." The new sorts that have been constantly introduced showing that the highest standard of excellence has not yet been reached, and that no fruit is so susceptible of high development as the Pear, as it advances step by step with the higher cultivation of man; this advance being by no means rapid, as it has taken many centuries to produce a Pear of the quality of the Doyenné du Comice, this fruit being far superior to any of those noticed by Lindley in 1831.

It is curious that Shakespeare, country bred, should never have mentioned Pears by name, save once, in "Romeo and Juliet," when he alludes to the Popperin Pear, now known in Worcestershire as the Poplar Pear, still one of the common perry Pears of the county. It is evident from this meagre notice of Pears that Shakespeare's tastes were not gratified by good fruit. In "The Merry Wives of Windsor" he uses the phrase, "crestfallen like a dried Pear." The plump and juicy Pears of our century when fallen rot before they wither, but the tough perry Pears wither before they rot. Worcestershire abounds with Pear orchards, and Shakespeare, had he seen these orchards in full bloom, would surely have expressed his admiration. There is no allusion in any of his plays, poems, or sonnets to the beautiful spectacle of a Pear tree sheeted with its snow-white blossoms. Another country poet, Robert Herrick, although enthusiastic in praise of Strawberries and Cherries, never alludes to Pears. Herrick spent the best years of his life in Devonshire, which must have been almost destitute of Pear trees. Sir John Suckling celebrates the charms of a young lady in his lines—

Her cheeks are like the Katharine Pear,
The side that's next the sun.

Batty Langley notices two Katharine Pears, the Royal and the Queen.

Standard Pears are utterly unsuited for small gardens, and should be grown in orchards only. Those who are blessed with old and decrepit standard trees may renew their vigorous growth by heading them down. In three years young, healthy, and fruitful branches will replace the old and useless wood of generations. A difference is sometimes observed in the conduct of trees on the Pear stock. Some will be more fruitful and bear larger fruit than other trees of the same sort and age. This arises from the influence of the stock upon the graft. All Pear stocks are raised from seed, and great variety of course exists. The difference sometimes seen in the produce of trees growing side by side is often so great as to cause doubts of the identity of the fruit. The seeding Pear stocks imported from France are raised from the pips of perry Pears, and of these two sorts are distinguished, one with smooth bright leaves from the district of Le Mans, and the other, woolly or sage-leaved, from the province of Anjou. I believe the pips of the wild or forest Pear are employed in Germany for raising stocks.

Garden trees on the Pear stock should be either trained as espaliers, wall trees, or pyramids. Root-pruning will cause unfruitful trees to bear, and those who

* A lecture by Mr. T. Francis Rivers, Sawbridge-growth.

have them will do well to practise it. The Pear stock is not fastidious about soil. My own experience of the Quince stock convinces me that it is the most useful stock for all styles of garden training, it is adapted for espaliers, pyramids, bushes and cordons. Cordon training, although known and practised in England for some time, has been brought more prominently into fashion during the last thirty years. It is, perhaps, the most simple and productive of all sorts of training. An oak fence, 7 feet high, planted with diagonal trees, 18 inches apart, in four years will produce a large quantity of fruit, and a wall from 12 feet to 15 feet high in five to six years will produce like results. I have found that pruning twice a year (June and October) is sufficient to keep the tree in fruitful order. In the June pruning the young shoots must be stopped at the fifth or sixth leaf, and in October every spur must be pruned as close to the main stem as possible, avoiding any injury to the fruit buds, which are, of course, easily detected, diagonal cordons may also be trained to wire trellises, and treated in the same fashion: this is a very interesting and ornamental style. The single horizontal cordons and the double horizontal cordons, trained at 18 inches from the ground, form a neat and fruitful edging to side walks. The five-branched vertical cordon has five upright shoots springing from a common horizontal base. These may be planted 4 feet apart. The horizontal cordon has the branches trained at regular intervals from a main vertical stem, this form is admirably adapted for espaliers by garden walks, and is very tractable and pleasant to manage. Vertical cordons planted in the open ground 4 feet apart will give large crops of fruit. Two forms of cordon training seem to me to be very unpractical—*i.e.*, vase-cordon and the plan of training over an arched trellis, the former is more trouble to manage than a bush tree and gives no better results, and the latter is contrary to common sense, part of the tree being grown in the shade. All cordons require the same system of pruning. Pyramid and bush trees on the Quince stock are charming garden trees; the pruning is somewhat different to that practised for cordon trees; the side shoots should be pruned in June, and the leading shoot untouched until October, superfluous shoots being occasionally removed during the summer to admit the sun; the unpruned leading shoot must be shortened back in October.

Garden trees require root management, and a modified system of root-pruning should be practised with all. A circular trench about 3 feet from the stem of the tree should be dug annually if the room for the tree is restricted, in the autumn the soil in this trench should be refreshed with manure and fresh soil, and a surface dressing of artificial manure applied during the spring. For the latter purpose soot, superphosphate of lime, and guano are probably the most useful. The trench and the manure will render the planter independent of the soil. If Pear-growing is to be made a certainty, cultivation under glass must be adopted. A glass house is of course a prime necessity; it may be as plain as possible for the purposes of protection. During the spring the trees can be packed closely, for in the early period of growth they do not require much space; about the end of May, or when all danger of frost is past, many of the trees should be put out of doors, leaving enough in the house to stand 3 feet from each other. The trees taken out of the house should be plunged in a border prepared for them, and the trees inside sunk in the soil up to the rim of the pot, the sides of the pot should be perforated, but that is not an absolute necessity. The trees should be surface-dressed with manure, and watered with manure water twice or three times a week, when under glass abundance of air must be given. Culture under glass makes a crop a certainty, and requires no more attention than is given to Melon or Cucumber growing.

Protection to cordon trees trained about 1 foot from the ground may be given by planks on each side placed on edge supported by short stakes and covered with mats during severe frost. Ground vineries also form very efficient protection, but they are not so cheap as the planks.

Raising seedling Pears is always interesting from the uncertainty which attends the pursuit. I have raised some hundreds from the best sorts known, which

I have crossed in every conceivable fashion. The "Conference" Pear, which gained the suffrages of the Committee of the Pear Congress of 1885, came from a baking Pear, the Leon le Clerq de Laval, the pips of which I planted without any special design. All pips intended for seed should be taken from the finest and best developed fruit.

The sorts of Pears of recent introduction selected by the Pear Congress of 1885 were the following:—

Beurre Gifford	Emile d'Heyst
Clapp's Favourite	Ben red Anjou
Summer Beurre d'Arenberg	Marie Benoist
Madame Trevoe	Pomme de Jonghe
Beurre Dunois	Rose Crassant
Pitumston Duchess	Duchesse de Bordeaux
President d'Osmanville	Olivier de Serres
Madame Andre Leoy	Nouvelle Pulvie
Conference	l. Inconnue

And for orchards and market gardens:—

Reaon	Marie Louise d'Uccle
Fertility	Burondeau
Souvenir du Congrès	

The improvement in Pears will no doubt continue, and in 1886 amateurs will wonder that we could be contented with fruit so inferior to that which they will enjoy, even as we are no longer satisfied with the fruits which charmed De la Quintinye and his friends.

NOTES OF THE WEEK.

Lily of the Valley fruiting.—One day lately when visiting a friend near here who has a very snug garden, I was surprised to find that this Lily had produced fruit. Every spray on which there were flowers in spring was bearing berries where the flowers had been. They were largest at the bottom and smallest at the top; bright transparent red in colour, and really very pretty.—J. Muir, *Maryon, Glamorganshire.*

Masdevallia tovarensis.—At various times correspondents of THE GARDEN have objected to the system of leaving old flower-stems on this Masdevallia, as by so doing it prevents a full crop of young spikes coming forward. In this I concur, but, at the same time, I like to leave a few old stems, for while the young spikes produce two and three flowers each, the old ones furnish five or six. I enclose you two spikes left from last year, each bearing six flowers.—FREDERICK BEDFORD, *Straffan House, Co. Kildare.*

Eupatorium odoratum.—I send you a small piece of this cut from a plant on the west end of a lateinery, where it stood with impunity the whole of last winter unprotected. It has been covered with its white blossoms for these two months past, and has afforded a good quantity of cut flowers. There are also still a good many to open if the weather is sufficiently mild. Coming in at this season it is especially valuable, and would well repay a little protection in colder localities than this is.—JOHN GARLAND, *Killerton, Etc.*

National Rose Society.—It is proposed that some sort of recognition of the Queen's Jubilee should be made next Rose season by this society. At a recent meeting of its members, the proposal was made and a special committee formed. It was decided that the first £100 of the subscriptions should be devoted to the purchase of two challenge trophies, to be competed for at the provincial shows of the society, one for thirty-six blooms, open to all nurserymen, and one for twenty-four blooms, open to all amateurs. Subscriptions were announced in sums varying from one guinea to five, amounting to upwards of £40, and circulars will be shortly issued to all members, inviting their co-operation.

New hybrid Cattleya.—A drawing of a beautiful new hybrid Cattleya has been sent to us by Sir William Marriott, Down House, Blandford. It is the result of intercrossing *C. Mendeli* and *C. guttata* Leopoldi, and was raised by the late Dr. Harris, of The Grange, Lamberhurst, Kent. Prof. Reichenbach has named it *C. Harrisii* in compliment to the raiser. The flowers are similar in size to those of *C. granulosa*; the sepals are of the clearest amethyst, dotted over the surface with numerous small purple spots; the labellum is of a very deep purple-crimson, while the centre is lighter coloured. In growth the plant more resembles *C. Mendeli* than its other parent, and

some of the bulbs have borne two leaves each, about 2 inches wide and 7 inches long. The bulbs are rather flat and furrowed. The drawing sent was made by Miss Harris, who must have found a difficulty in representing the brilliant hues of the flower.

Cotoneaster affinis.—I send you a few small branches of this Cotoneaster heavily laden with berries, with which the whole of the plant, which is about 35 feet high and as much or more through, has been quite covered. The long branches are full of fruit-bearing spurs, and are laden with berries as well as the wood of last year's growth, all drooping under their heavy weight of fruit, which is produced in large clusters. As Holly berries are scarce with us this year, we have been using those of this Cotoneaster for Christmas decoration. As you will see, the plant has retained its leaves quite green up to this time, although on several nights the thermometer has been down to 20° Fahr., and some days has not been higher than 32°. It is a shrub admirably adapted to plant on the outskirts of plantations and game preserves, as it produces every year enormous quantities of fruit, of which pheasants especially are fond.—JOHN GARLAND, *Killerton, Etc.*

Pæonia Whitleyi.—"D. K.," in his excellent description of *Pæonia albiflora* and its varieties in a recent number, describes *P. albiflora* var. *Whitleyi* as double. I have a variety called *Whitleyi* single, which he does not appear to mention. I believe it is a variety of *P. albiflora*, and is known as *Whitleyi* single in several English nurseries. In a good season, such as the last, this variety is magnificent, the flowers being pure white, with a cream-coloured centre. The plant grows from 2 feet to 3 feet in height, and blooms about the same time as the other herbaceous *Pæonias*—that is, towards the end of June. Perhaps this variety may be identical with one of the varieties "D. K." has described; if so, it would be well to know that, as confusion may arise.—D.W.

Covent Garden Market.—The supply of flowers sent to this market this week has been both large and varied. Amongst the host of the good things which we noted were the red and white-bracted forms of the Mexican Flame-leaf (*Poinsettia*), exceptionally fine; white Azaleas, Chinese Primroses, both double and single, the latter extra good, especially the coloured varieties. Associated with these were also the yellow and white Marguerites, the white being perhaps the best plant grown for room decoration, producing a chaste and elegant effect in any situation. Chrysanthemums, chiefly whites, are still in good form; also Lily of the Valley, Roman Hyacinths, and Tulips of several shades. Some pretty combinations may likewise be seen, such as Lily of the Valley, red Tulips and Ferns, Roman Hyacinths, Ferns and red Tulips. Persian Cyclamens are also well represented, from pure white, through various shades of pink, rose and purple, to crimson. Various kinds of Heaths are numerous, especially the winter Heath (*Erica hyemalis*), which has seldom been seen more floriferous than it is this season. Berried plants consist chiefly of Solanums, which should sell well this year, as the Holly is but thinly berried. Cut flowers comprise Chrysanthemums in various shades of colour; Roses in abundance, Arum Lilies, Eucharises, Camellias, Narcissi, Hyacinths, Bouvardias, zonal Pelargoniums, pink, white, and scarlet, both double and single. Amongst Orchids are fine examples of *Calanthes*, *Princess Alexandra Odontoglossums*, *Lælia autumnalis*, *anceps*, and *albida*; the beautiful *Odontoglossum Rossi* in several varieties; *Oncidium Jonesianum*, *Rogersii*, and *varicosum*; the scarlet *Sophronis grandiflora*, and the Violet-scented *Dendrobium heterocarpum*. *Lycaste Skinneri*, with its large, bold, wax-like flowers, is especially noticeable, whilst *Cattleya marginata* blooms are very abundant. Fruits are numerous and good, especially the Smooth Cayenne Pine from the Azores, Custard Apples from Madeira, and Lychees and Jaffa Oranges. Pears and Apples are numerous and good, particularly American Baldwins and Ribstons. Asparagus, Sea-kale, and Rhubarb are plentiful; as are also Truffles, and small salading is in great variety and abundance.

Twin-flowered Cypripedium (J. H.).—Not an unusual occurrence, numerous instances of which occur every season.

WOODS & FORESTS.

ENGLISH FIREWOOD.

THE brightness of the glowing logs upon the hearth is one thing; the snow covered trunks upon the ground outside is another. When we see some of our finest trees and shrubs, the glory of the garden and pride of the wood, reduced by one night's storm to the value of ordinary firewood, one is a little tempted to hate the very name; it seems a poor finish for some glorious Rhododendron or specimen tree which may have attracted much notice or been of great beauty hitherto. Still, it is something to feel that one may be of use even in one's ruin, and such must be the consolation in more than one instance. The writer of the article in last week's number did not allude to one of the best woods for burning, viz., Birch, nor to the worst, Spanish Chestnut. We have fires going through the whole of the winter of nothing but Birch, and it has the advantage over Oak and several others on account of seasoning more quickly, and not retaining the sap so long when left in the log unsplit. The rough bark when dry always makes a cheerful blaze, and, in fact, the whole of the Birch is good for burning, from the smallest twig to the biggest stem. Spanish Chestnut, on the other hand, should be well guarded against; it slips in sometimes among the other cordwood, and then woe betide the hearthrug and the carpet; the finest fireguard does not seem proof against the spluttering of the sparks from it, and really serious damage may sometimes be done if no one happens to be in the room at the time. It is a good plan to have a special store of wood from any of the Cedar tribe, from which a piece or two may be thrown on the fire occasionally. It burns very brightly when dry and with a pleasant smell, often serviceable to counteract that arising from cooking, when the latter, under the guise of an accident, presents itself "even in the best regulated families." I suppose that most people know that the success of a wood fire often depends on the ashes being allowed to accumulate; but it appears necessary sometimes to give injunctions against their removal.—C. R. S. D., *Sussex*.

— Having for many years had to burn a good deal of wood for ordinary fuel, I give the preference to goodsound Oak that has well matured its growth; the size is of not so much consequence as the age. I do not include in this consideration fagot-wood, but such as is ordinarily used in the place of coal. The merits of the Oak, or, for that matter, any other sort of tree as furnishing the best firewood, depends entirely on its age. The wood of a young tree twenty-five years old and less is inferior both in heat-giving and lasting qualities to that of fifty or a hundred years older. But in all its stages the Oak is unquestionably the most valuable. The Ash stands next in the point of merit as regards heating and lasting qualities, and it has the advantage of being more easily prepared. It is this feature which I think has made the Ash so popular as fuel, but it is inferior to the Oak in any stage of growth, and particularly when it is declining in age. The bole of an old Ash tree that is much decayed is, in my opinion, of but little value for heat-giving, although it may ignite quickly and burn rapidly. I place the Elm next on the list, because in a half green state it burns freely and gives out a good heat. It requires less to ignite it when it has laid by twelve months if kept quite dry, but it is quickly consumed, and in this condition its heat-producing qualities are not remarkable. Beech I consider to be disappointing; its appearance would lead one to believe it to be a long-lasting and heat giving fuel, but it is not so as compared to Oak and Ash, and the older it is the less value it is for fuel, as in that condition it does not burn very freely. The Sweet Chestnut and Sycamore I think are of about equal merit; they are both light woods which when in a dry state burn freely, but do not last long. The above named woods are available in a greater number of places than any others we can name, if

we except the districts in which Fir plantations are numerous. In my opinion none of the Fir tribe will bear comparison with any of them; as a matter of fact, they cannot be used with safety in any living rooms on account of the sparks of fire which they send out. With regard to Apple and Pear tree wood, I should place them as equal to the Ash when in a condition fit for burning, but neither of these woods are of much value if the tree has lived long enough to die away in a gradual manner, but the wood of either from a tree that has been blown down when in its prime, and prepared and burnt six months afterwards, leaves little to be desired, as the wood burns steadily and throws out a steady stream of warmth. If I was asked to name the wood that gives the greatest heat over the longest time, I should put the Yew first, then the Holly, and next the White Thorn, but these only being available in limited quantities, in the majority of cases cannot be considered as of special value as firewood trees. Oak is in its best condition for fuel within the first twelve months after the tree is cut down; Ash is better used within nine months, and Elm six months.—J. C. C.

* * * The Ash has a precious and rare quality in burning well and brilliantly immediately after being cut. We want more light on this interesting question, and we invite further discussion upon it.—Ed.

WOODLAND NOTES.

GAME COVERTS.—These should never consist of dense masses of Evergreens, although such is the prevalent idea, for game as a whole detest in a marked degree such plantations as are surfaced with underwood. What they like best is clumps, thick as you like, of Evergreens placed at such distances apart as will allow of their feeding and sporting in the full sunlight that warms up the open ground between the various patches of covert. To meet this want we always, in forming game coverts, mark off the various clumps at irregular distances apart, and, if possible, so as to look best and most natural from adjacent walks and drives. The clumps should not be too large, say, to contain from sixty to one hundred plants in each, be irregular in outline, and at irregular distances apart. At first, and more particularly where immediate effect and covert is required, plant the Evergreens doubly thick, and when the outer branches begin to encroach upon each other remove every alternate one, thus giving the remaining ones plenty of room for full development. In the case of the Laurel and Laurustinus, pruning after a year or two had best be resorted to, for if these, more particularly the former, are allowed to grow at will, a dozen years hence will find them but bare poles with a tuft of foliage at the top, and totally unfitted for the purpose intended. To remedy such errors in game coverts is, however, not impossible, for if the long branches are pegged down firmly in a circle around the parent stem, they soon throw out numbers of shoots and in two years form excellent covert. Pruning should, however, be engaged in at least every second year, the long top branches being cut back to, say, 4 feet from the ground, thus throwing the whole strength into the production of numerous fresh shoots and so rendering the covert a perfect hiding-place for the game. Privet as a game covert rarely receives the attention it should, for most persons are under the very wrong impression that to form coverts of this plant you have only to plant and leave alone. This is not so, for in order to have profitable Privet coverts, annual pruning, and in most cases pegging down of the outer and stronger shoots, must be resorted to. Another point in the formation of game coverts that must by no means be passed over is that, in order to be successful in the management of such, plenty of light and air must be admitted to the woodlands, and to have such well-thinned out woods and plantations are all-important.

COLLECTING AND STORING TREE SEEDS.—Tree seeds in general should always be collected from healthy, middle aged specimens, not such as are crowded together or grown in a low-lying, shady nook, but from those that are fully exposed and growing at a moderate elevation. In collecting, do not cut the

branches containing the seeds from off the trees, but either gather them from a light ladder or by ascending the tree and drawing the branch towards the hand by a hooked pole. In the case of cones, the better plan is to ascend the tree to a few branches above those on which the seeds are, and by gently drawing the branch upwards with the hooked rod the cones can readily be removed without either damage to the branches or cones. See collecting by contract should never be permitted on any estate, unless, indeed, under the most careful and strict overlooking, but should be performed by the nurserymen or others acquainted with the work. A light ladder of about 20 feet long is of great value in seed-collecting, as it not unfrequently happens that the seeds are at the very tips of the longest branches, and quite out of the reach of the person who climbs the tree. In such cases one person holds the ladder with its top end resting on the branches, while the other ascends and collects the seeds into a bag or apron provided for the purpose. Now, as to storing: My advice, from a rather intimate knowledge of such work, is, do not store the seeds away in bags; there are exceptions to this rule, but they are few; but in the case of such hard woods as the Birch, Sycamore, Plane, Ash, Elm, Alder, Lime, Poplar, and Willow, place the seeds, after being thoroughly dried, if possible, in the sun-heat, in shallow boxes, and store away in a dry, airy loft till wanted for sowing. The objections advanced against storing quantities of seeds away in bags is, that dampness too frequently permeates the mass, and the vitality of the seeds is endangered thereby. Cones of the Pine tribe may be placed in baskets or boxes, the seeds being allowed to remain in them until wanted for sowing. In the case of *Abies nobilis*, *A. grandis*, *A. magnifica*, *A. Nordmanniana*, and, indeed, most of that section, the cones fall to pieces when removed from the trees, and the seeds consequently require storing away until sowing time comes round. We treat these similarly to the hardwoods above described, unless, perchance, in the case of very rare seeds, when perhaps a little extra care is bestowed. Berries of all kinds require to be placed in sand previous to sowing—at least, such is the usual method of treatment; but from this method we are now departing fast, for if ground is at all plentiful, we sow Holly berries, as well as those of the Yew, *Eunonymus*, *Skimmia*, *Cotoneaster*, and most others when collected. Of course, by so doing but very few plants appear the first season; but never mind that; the second year, if your seeds have been good, will find plenty and to spare.

SEED BEDS AND THEIR MANAGEMENT.—In certain soils the raising of seedling forest stuff is easy enough, the most difficult task being to retain them after they have been raised, and while still in the seed bed. Worms, by burrowing beneath the roots, commit much damage to young seedlings, particularly those of the Pine tribe, while frost not unfrequently raises the young plants quite out of the ground, thus causing serious injury to the tender rootlets. As an antidote to both of these evils we have of late been very successful by using fine river sand for scattering over the beds, and which when washed down amongst the soil has a wonderfully deterring influence or effect in staying the underground operations of worms, as well as preventing, to a great extent at least, the upheaving of the ground by frost, the fine particles of sand soon falling back into the ruts and grooves caused by the frost. Some two or three beds of Conifers were badly treated by worms boring under the young trees, lifting them, in some cases, bodily out of the ground, and thereby killing many. Various would-be preventives were resorted to, but nothing has so effectually stayed further molestation than a half-inch coating of fine sea sand that had been allowed to lie fully exposed to the weather for a year before being used.

ORNAMENTAL HEDGES.—In our home nursery we have tried most shrubs that, from their habit of growth, could be considered as suitable for the formation of hedges. Amongst all these, nearly thirty kinds, the Yew, Box, and Laurustinus still hold their own, and are particular favourites. What a pity it is that the poisonous qualities of the Yew preclude its use for farmers' fences, for its neat habit of growth, non-impoverishing tendency, ease of culture, and amount

of shelter it affords are all first-rate qualities in a hedge plant. For ornamental grounds or, indeed, anywhere that farm stock cannot browse on its leaves, the Yew is invaluable, and should be used largely. The Box forms a capital evergreen, ornamental hedge that is of great value for dressing grounds, the nursery, or the garden. It bears cropping well, forms a dense, stiff hedge, and is anything but fastidious about soil or exposure. As a really ornamental hedge perhaps few shrubs surpass the Laurustinus for the formation of such. Unfortunately, during severe winters it is apt to get cut down, but if pruned back in early spring, it soon recovers, and sends out numerous strong shoots, which in less than three years have attained to the size and luxuriance of their predecessors. Other shrubs that from experience we can highly recommend for hedge-making are the Portugal and common Laurels, the Barberry, Euonymus, Holly, and Arbor-vitæ.

EVERGREEN COVERT.

THE above term is commonly employed to denote such trees or shrubs as grow naturally, or are planted for covert under the shade of the taller forest trees. The kinds that thrive in such situations are not very numerous, for there are not many trees that grow well in the shade, and some of those that do grow, those depredators, the rabbits, frequently destroy in hard winters. Besides, there are some kinds of forest trees under which scarcely anything will grow, owing partially to the density of their shade and their habit of rooting near the surface of the ground.

In Oak and Ash plantations, however, there is always plenty of undergrowth, and in mixed plantations generally there is not much difficulty in getting up a good covert. Oak woods, or woods consisting principally of deciduous trees, have a naked and dreary aspect in winter if they be not relieved by evergreen undergrowth of some kind, and it is not often they are furnished to any extent in that way. Sometimes a few Spruces or Scotch Firs afford here and there a little shelter, and impart a warmer aspect to the scene, but some have an objection to these, and they are the first to be removed when thinning takes place. When travelling by the train miles and miles of woods may often be seen in which hardly a green leaf is visible during the winter months. How different the aspect of things when the wood happens to be well sprinkled with green Holly trees; and there is no better subject than the Holly for relieving a wood of its nakedness in winter.

A wood may be completely transformed in its winter aspect by planting it with Holly. When the tall trees are leafless, and the Bracken brown and dead, the Holly shines out green and glistening in all its beauty. Besides, it has a recommendation from a sportsman's point of view. The Holly is a warm tree, and the birds flock to it in winter, especially the sparrows. When snow is on the ground, if there be a bare or warm spot in the wood, it is under and around a Holly tree. The snow always melts away near it, and at such times you are almost certain to start two or three pheasants from amongst its lower branches if there be any pheasants in the wood; this we have observed many a time ourselves, and gamekeepers will tell you the same story.

Where game is reared, therefore, we should say the Holly is one of the very best subjects to plant as underwood; there are none more suitable, for it stands shade better than any other Evergreen. The common Laurel grows tolerably well also, but straggling, and it should be cut down occasionally; rabbits do not eat it, and it affords them excellent shelter. The Rhododendron, of course, is well known for being almost rabbit-proof, and it also grows under the shade of other trees, but it must not be expected to flower freely in such quarters. The Yew is another tree that grows pretty well in the shade, though it gets thin in the branches in course of time. Nothing approaches the Holly, however, and it soon grows to a large size.

Unfortunately, rabbits often bark the small plants, but I have not seen them meddle with anything but the outside branches of the older trees. Where rabbits are to be feared, planting should always be

deferred till April or May, when all danger from their attacks is over; besides, that is the best season to plant Hollies. Tolerably large plants with bushy bottoms are preferable to those of other shapes for planting in the woods. For this purpose the best plan is to grow the trees in the home nursery for a year or two, giving them plenty of room, and afterwards remove them to the woods. They may be planted anywhere under the trees, but at the same time the most favourable spots as regards light should be selected for them. S.

THE WOOD OF THE BEECH.

THE Beech, says a writer in the *Timber Trades Journal*, is one of the most useful British timber trees, although others are much more costly. It is well adapted for indoor work, but is less suited for use out of doors. In its natural state it is largely used for cogs and where hardness is required, and when properly treated in felling, drying, and preparing, it is not superseded by any other kind of English wood. The Holly, the Hornbeam, the Thorn, the Crab, &c., are often substituted for the Beech, but if treated in the following manner it maintains a decided superiority over these: When the Beech is to be used as mentioned, it should be felled during the months of December and January, but a few weeks prior to felling, several gaps should be chopped in the tree near the roots, in order to allow it to get rid of its sap freely. As soon as possible after felling it should be cut up as required, and put under cover in a perpendicular position. Often it is utterly spoiled by being laid aside horizontally, in which position it cannot dispose of its sap; consequently its hardest properties are destroyed, and it is thereby rendered practically useless for the best purposes for which it is required. The growth of the Beech is very rapid, and it attains its prime in about from sixty to eighty years. Up to this age it is seldom deceptive when grown in plantations. If, however, it is permitted to grow much older than this, it often becomes black-hearted, and this condition is followed by rotteness and shakes. In this state the wood is worthless for manufacturing purposes.

The Beech is generally deceptive when hedge-grown, the reason being that its early growth requires great tenderness and protection. Grown thus, it is exposed to blemishes of various kinds, and these turn black, the stain remaining in the wood ever afterwards. When stains occur the wood is valueless for steaming. About three-fourths of the Beech is now steamed, as this process greatly improves its colour. The more sap it contains the better it will steam, and a skilful person can give the wood a very bright hue by careful steaming. If it is allowed to lie several months after being felled it can seldom be used for the best purposes to which steamed Beech is put. Steaming does not improve its strength as it improves its appearance; it rather reduces this quality, though strength is seldom required where steamed Beech is used. We may here mention that joiners, when buying planes, frequently ask for red, or, as they call it, "male" Beech, in preference to the white or "female" Beech; but if they were better acquainted with the process of steaming they might possibly reverse their preference, for it is by this process that the red hue is produced.

The Beech develops a great quantity of sap, and feeds itself very much from its leaves. During a dry spring it will scarcely move its bud, but after a shower of rain it is soon in full leaf. Its growth always ceases early in the autumn. When required for steaming it should not be felled when in full leaf, but in the months of October and November, and again in April and May, when it contains most sap.

The best qualities of Beech are grown on red or light land, and when protected by other stronger kinds of timber trees. The quicker it is grown the larger it is bated, and the finer it is flowered and grained. It seldom attains to a large size in the open, and on account of the smallness of its roots it is more liable to be felled by the forces of Nature in open situations than most other trees would be. In cutting up Beech timber when fresh and full, half an

inch to 1 inch should always be allowed for shrinkage. There is only one other English timber, the Lime, which shrinks so much in drying. There are two kinds of Beech; one kind bears fruit and the other does not, and in the opinion of some the fruit-bearing tree is the softer of the two.

UNDERWOOD PLANTATIONS.

IT is only in exceptional cases that underwood is to be recommended in plantations grown for profitable timber. In some districts, according to a writer in the "Scottish Arboricultural Transactions," a considerable revenue may be derived from underwood, but when thoroughly looked into, it may be found that the gain is merely apparent, being to a great extent obtained at the expense of the timber crop. On the other hand, there are many neighbourhoods where there is comparatively no demand for underwood of any description; and where such is the case, the growing of underwood adds to the expense of management, and is detrimental to the standing trees. It is certain that ground cannot carry two crops at the same time without one of them suffering. Where there is a heavy crop of underwood, it must absorb much nourishment from the soil, and deprive the timber trees of a great portion of the food necessary for their healthy development. Further, the roots of underwood form a network in the soil, which should be left entirely for the spread of the roots of the trees. The same reason may be adduced in favour of nursing hard-wood trees with Firs instead of hard-woods, as the latter not only throw out growing shoots from the stools, but their roots continue to spread, and thus deprive the trees of the full benefit of the ground in which they are planted. Another objection to the growing of underwood amongst hard-wood trees is the amount of shade caused thereby, shutting out in a great measure sunlight and air, and thus defeating the objects of thinning plantations. In these observations I do not condemn the growing of underwood under all circumstances, but merely in conjunction with a crop of hard-wood trees. It must be admitted that there are exceptional cases where it is advantageous to grow underwood in hard-wood plantations, as in very exposed districts; but then only round the margins, and in well-selected masses throughout the plantation. Underwood may be grown for cover in game preserves, or in clumps for ornamental purposes, and along the sides of drives or rides, but for the reasons above set forth in most other cases it is open to serious objection. It has been said that the ground should be thoroughly drained before planting, especially where there is any tendency to wetness. In most cases open ditches are preferable in hard-wood plantations. They should not be less than 2 feet deep nor more than 30 feet apart. Open drains should also be run along the sides of all plantation roads and drives. All open drains require to be inspected periodically, as they are soon filled up by the falling in of the sides, growth and decay of herbage, &c., and it is especially necessary to overhaul them after every thinning, as many will be choked by the branches of the fallen trees. The distances at which hard-wood trees should be planted depend upon the soil and situation of the proposed plantation. In all cases it is necessary to calculate the size they are likely to attain in such soils and situations. Trees, if planted at too great distances apart in exposed situations, are liable to severe checks from cold winds, &c., and do not attain the height they would do if planted more closely, and sheltering one another. Thick planting is the safest method to adopt, provided thinning is attended to in proper time, before the trees injure one another.

Timber measuring.—"A. P." is correct in the simple method of measuring a cylinder. But are all trees of a cylindrical shape? If I understand rightly, the definition of the word "cylinder" is a roller-like body, solid or hollow, of uniform circumference. Therefore if this be true, we cannot call many hard-wood trees cylinders, and as for cross-cutting trees to meet this rule it would be a useless consideration. Therefore, in my opinion, we had better adhere to Hoppus's "Practical Measurer."—YOUNG FORESTER

No. 190. SATURDAY, Jan. 8, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART IS-SELF IS NATURE."—*Shakespeare.*

PROFITABLE ASPARAGUS CULTURE.

It is stated that Asparagus was one of the first of culinary vegetables whose growth was accelerated by artificial means, and that before the middle of the seventeenth century the London markets were supplied with forced Asparagus at a very early period of the year. About sixty years ago, a good authority stated that at that time Asparagus was brought into Covent Garden from the beginning of November onwards in greater perfection than to any other market. At that time the supply was probably exclusively English. Cheap and ready means of transit from continental countries was not then thought of, and the demand for it was very limited indeed compared with what it is now. Fresh, sweet Asparagus, forced or otherwise, is one of the most esteemed of vegetable productions, and it ought to be better known than it is that Asparagus requires a less degree of heat to produce it in perfection than almost any other vegetable. Of course, the method of forcing it is very different from that of Seakale; for instance, we can force the latter in the Mushroom house, in a warm cellar, or wherever there happens to be heat and darkness, but we cannot in that way deal with Asparagus. It is, nevertheless, very easily forced, but those unaccustomed to deal with such matters may easily do irretrievable damage to the roots. I have been tempted to take up this subject because of its importance to cultivators of small gardens. There has been of late a strong feeling in favour of allotments for cottagers and others, but all such changes must be gradual; I have, however, no doubt that any labourer anxious to obtain ground to cultivate would find no difficulty in doing so. I have known labourers who have managed a large plot of garden ground and done well with it, but they carried the produce to their customers themselves; their highest attempt at producing vegetables was early Cauliflowers, Celery, and out-of-door Cucumbers. Nothing seems to be grown except such as would produce immediate profit. This Asparagus will not do, and consequently it is not grown in small gardens. I have, however, a notion that where land is cheap Asparagus culture might be made profitable even in a small way. Each allotment garden ought to be furnished with two or more frames with glass lights. It is certain that those who possess such frames have a great advantage over those who have to depend for their own and market supply of vegetables wholly from the open ground. Asparagus is easily raised from seeds, and three-year-old plants when well managed will do well for forcing. Anything older, up to thirty years, will do equally well.

I am not about to allude to any expensive system of forcing by heated pits, &c., but merely to point out the value of ordinary garden frames for the purpose of keeping up a supply of good Asparagus. The best fermenting material, if it can be obtained, is a mixture of equal parts of manure and leaves; but either of them may be used separately. The heap should be built up to a height of 3 feet, or more; but if the manure is fresh, it ought to have been turned over twice, at intervals of five or six days, before building it up in a heap. If it is likely to get too warm, it is necessary to wait until the first violent heat has subsided; after that level the surface and tread down. The next process is to place over

it a layer, 2 inches or 3 inches deep, of ordinary garden soil; on this pack closely the roots, which have been carefully lifted from the ground. From 100 to 600 roots may be packed into a three-light frame according to their size. Some fine mould should again be shaken over the crowns, covering them to the depth of about 3 inches. I would like to add here that where turf can be cut, it may be laid over the manure with the grass side down.

It is a good plan to sow over the surface some Radish seeds, and in this way the frame will produce two crops at one time. It will depend a good deal upon the heat in the bed whether the glass lights should be kept close or tilted at the back, which is the best way to admit air if necessary. If there is not much heat the buds will come stronger than they otherwise would do, and the frame may be kept close, except for a few hours at mid-day in fine weather, when the lights may be tilted an inch or so at the back. It must not be forgotten that air and light are essential in order to give strength, colour, and flavour to the shoots. Air is also very beneficial to the young Radish plants, which will grow very rapidly, and may be almost as valuable as the Asparagus. On frosty nights mats may be thrown over the glass; these will make a difference of quite 5° or more in the temperature of the frame. In some cases the heat of the bed subsides suddenly, and growth is thereby much retarded. I have found it to be an excellent plan to build the manure over a layer of fagots a foot thick; in the event of the heat unexpectedly subsiding, linings of hot manure a foot thick placed round the frame and carried up the wood of it will bring the heat up again. The heat also works in amongst the fagots and upwards through the manure.

When Asparagus is forced in frames it is easily blanched, if need be, by covering the glass night and day with thick mats, but in that case small salads, such as Radishes, cannot be grown in the same frame. The almost universal taste in this country is for the buds, as they are termed, to be well coloured by exposure to light, and, as much as possible, to fresh air daily. In cutting the shoots, it is well to remove the soil a little with the fingers, in order that the buds which have not yet appeared above ground may not be injured. Water is seldom required at mid-winter, but in the early spring months it may be necessary to water the beds, if they are likely to become over-dry. Those who may obtain large garden allotments would do well to turn their attention to Asparagus, not only for forcing on hotbeds, but as a paying crop from the open ground. There cannot be any reason why we should not be able to compete with French growers in this matter. This is on the assumption that each grower should be his own salesman.

If a supply of good Asparagus was forthcoming, it is likely that a good demand for it would follow. As a rule, country towns are very inadequately supplied with good vegetables, and such as are to be obtained fetch good prices. The reason is obvious: large growers send everything to London. Small growers would not do this; they would dispose of their bundles of Asparagus either to private customers or to the greengrocer in the next town or village. London has been and always will be supplied by the large growers. The holders of allotments will therefore have to make a market for themselves, and this can only be done gradually. J. DOUGLAS.

Quercus Daimyo.—This is one of the noblest of all Oaks, and one of the rarest among the species cultivated in this country. It surpasses all others in the size of its leaves, which often

measure over a foot in length and half as broad as long. The leaf is deeply lobed, broader at the top than at the base, and of a pale green. Being Japanese it cannot be strictly called a hardy tree except in the southern counties, but even in the most favoured parts of the country it will probably never grow into a big tree. But the foliage is so large and handsome that it is worth growing even if it only got a few feet high. It is best to plant it in a sheltered nook where it would show off its great leaves and yet be protected. It retains its old leaves till the spring, and some would think this a drawback, as the foliage has a rusty look in winter. It is catalogued by a few tree nurserymen under the name of *Q. Daimyo*, though its correct name is *Q. dentata*.

ORCHIDS.

THE CIRRHOPETALUMS.

THESE constitute a somewhat large family of small growing Orchids, some of which are exceedingly beautiful, although they appear to have lost favour to a great extent with Orchid growers. A few years ago many of them were to be found in our plant stoves, the Kew collection being specially rich in good examples of plants belonging to this genus. They are all dwarf in habit, and thus occupy but little space, more especially as they thrive best in small hanging baskets, and in such a position their umbrella-shaped trusses of singular flowers are displayed to the best advantage. The baskets in which these plants are grown should have a few pieces of light drainage material (such as charcoal) placed in the bottom, and the remaining space should be filled with fibrous peat, from which all the particles of fine mould have been shaken. Over this should be spread a thin layer of growing Sphagnum Moss, upon which the plants should be firmly pegged. They enjoy an abundant supply of water; during the growing season the plants must even be taken down and dipped in water two or three times during the week. But in winter very little will be sufficient for their requirements; indeed, we have found them benefited at this time of year by entirely withholding water from them for a short time. Great care must, however, be taken to avoid the shrivelling of the pseudo-bulbs, or the plants will be permanently injured. They enjoy heat and moisture, and if well exposed to the sun's rays they are sure to bloom freely. Before the flowers expand they should be moved to a shady situation in order to prolong the beauty of the blooms, which are thin and fragile in texture, whilst the leaves are thick and leathery. Amongst the most beautiful kinds that we have grown are *C. chinense*, which has a creeping rhizome or stem, and small ovate pseudo-bulbs, each bearing a bluntly-oblong, thick and fleshy leaf. The umbel of flowers measures from 3 inches to 4 inches across; the upper sepal and lip are purple; the lower sepals much lengthened and bronzy-yellow in colour. As evidence of the singularity of its blooms, a writer, in first describing this species, thus expresses himself:—

We have here a plant from China, one of whose lobes is so like a tongue and chin, and so unstable, as to be in a state of continual oscillation. The flowers are arranged in a circle, and all look outwards, and on whatever side the umbel is regarded, it still presents to the eye the same row of grinning faces and wagging chins.

C. cornutum is another grotesque kind, the flowers of which are yellowish white and purple, tinged with emerald-green and dotted with purple. They are usually produced in early autumn. It comes from Northern India and thrives in a cooler atmosphere than any of the other kinds, but does not object to a high temperature during summer. *C. Cumingi* is a small-growing and somewhat delicate plant, but the extreme beauty and peculiar structure of its reddish purple flowers well repay the extra care which it requires to maintain it in a healthy condition. The blooms appear about midsummer. It comes from Luzon. *A. fimbriatum*, from Bombay, usually blooms in spring; the pseudo-bulbs are clustered, not set

upon a long, creeping stem; the petals and upper sepal are red in colour and beautifully fringed; the prolonged connate lower sepals are greenish yellow. In *C. nutans* the flowers droop; they are sulphur-yellow in colour, and appear in great profusion towards the end of summer. It comes from Luzon. *C. auratum* is another elegant species from the island of Luzon, and produces its flowers in spring; these are pale yellow, suffused with crimson, and bordered with golden yellow; its large, umbrella-like trusses of flowers are produced very freely. *C. Macraei* is a species with small, clustered pseudo-bulbs, its umbels of bloom being produced during July and August; the upper sepals and the petals are reddish brown, tinged with purple, the lower sepals being yellow flushed with purple. It comes from Ceylon. *C. Thouarsi* produces a creeping stem, and its umbels of flowers appear in July and August; the small upper sepal and the petals in this case are yellow dotted and freckled with reddish purple; the lower tongue-like sepals are of a bronzy orange hue. It comes from Java. *C. Pahudi*, another Javanese kind, is a bold, robust-growing plant, the crown-like truss of flowers of which is much larger than that of any of the previously-named kinds, and from the peculiar manner in which the long upper sepal and the petals are turned back, it has a very striking and singular appearance. The colour is reddish brown, dotted with deep red and purple. It blooms about mid-summer. *C. Meduse* is more curious than beautiful. It is a free-growing plant, and one which should be grown in a pot; the scape is erect, bearing upon its summit a large, dense, globose head of flowers, which are pale yellow, freckled with pink; two sepals of each flower are lengthened out into thread-like filaments, several inches in length, a circumstance which has caused it to be called the Medusa's Head. It blooms during the summer months, and comes from the neighbourhood of Singapore. W. H. G.

Angræcum bilobum Kirki.—This is a little gem among Orchids, combining quaintness and beauty in a remarkable way. The following description from a plant now in flower in the Kew collection may interest Orchid growers. It is stemless, the leaves about 4 inches long, forming a tuft of about half-a-dozen. At the ends they are split, so as to form two distinct lobes; hence the name. The flower-spike is short, and there is only one flower on the Kew plant. This is about an inch across and pure white; the spur is 2 inches long, slightly twisted, as slender as a mouse's tail, and fawn-coloured. Sir John Kirk sent home this variety from Zanzibar a few years ago, but the original *A. bilobum* comes from New Guinea.

New variety of *Lælia anceps*.—In Baron Schroeder's Orchid collection at The Dell, Egham, there is now in flower an exceptionally fine new variety of *Lælia anceps*, which, so far as is known, has never been equalled in size of flower or splendour of colouring by any among the multitude of forms that have flowered in this country of late years. In form of flower it most resembles that unique variety *Dawsoni*, which is always regarded by orchidists as an ideal flower, as regards shape. This new form, however, eclipses *Dawsoni* in size of flower, and looks more like *L. elegans* in this respect. The sepals are deep rose-coloured, deepening towards the tips to an intense crimson, a colour which also extends to the lip, the splendour of which is enhanced by a clear yellow blotch in the interior. This is the first time in which this plant has flowered since it was imported by Messrs. Sander among a large number, and it is doubtful if another so remarkable will be flowered from the same importation.

***Cypripedium tonsum*.**—Probably only a *Cypripedium* fancier would look upon this newcomer as an acquisition. To speak plainly, it possesses no great amount of beauty, but it is distinct. It is different from any other *Cypripedium* with which we are acquainted. It most resembles that new variety of *C. Lawrenceanum*

which lately appeared in a Belgian garden, and named *Hyeannum*. *C. tonsum* has a very large flower and handsomely mottled foliage, even equal in that respect to *C. Lawrenceanum*. The dorsal or uppermost sepal is broad sap-green in colour, lined with a deeper green and edged with white. The lateral or side sepals are green also, and marked irregularly along the centre with a few dark, almost black, spots. The pouch or slipper is brownish red, lined with the same colour, but brighter. It is, we believe, a hybrid, and, if so, we should guess *C. Lawrenceanum* and *C. Dayanum* are its parents. It has been certificated, we believe, by the Horticultural Society of Ghent, but what merit the committee could have seen in it compared with others of a similar stamp is not clear, judging by the specimen of it which we saw in bloom a few days since.

***Catasetum longifolium*.**—This is one of those strange-looking Orchids in whose flowers one fancies he sees a resemblance to some kind of animal. In looking at the specimen in bloom in the Orchid house at Kew the other day, the spike of flowers looked to me like a shoal of small brown fishes facing me with open mouths. There are a score or so of flowers on a spike about a foot long, and each bloom consists mainly of a distended pouch with an open mouth of a sort of coffee-brown colour, and the short, erect sepals of the same colour look like ears, and the fringe which surrounds the pouch adds to the unflower-like appearance. This singularity would not be thought much of, perhaps, by those who like showy flowers, but the interest attached to it compensates for lack of high colour. It is one of the many weird denizens of the Demerara forests.

The pink *Sophranitis*.—The rose-coloured variety of *Sophranitis grandiflora* ranks, in the estimation of Orchid growers, on a par with such rarities as the pure white *Cattleyas* and albinos of other coloured-flowered Orchids. Until we saw it in bloom in the Handsworth Nurseries the other day we thought that Mr. Peacock, of Hammer-smith, was the only possessor of it. It needs no description, as it is the exact counterpart of a fine form of the scarlet *S. grandiflora*, except in the colour, which is a delicate rose. Artists perhaps would describe it as a rose-madder. It is one of the daintiest little Orchids we have seen for a long time, and the effect of several flowers on a plant, as at Handsworth, may be better imagined than described. It is singular that this rose variety has not turned up oftener, considering the large quantities of *S. grandiflora* that have been imported. An excellent coloured plate of this variety was given in *THE GARDEN*, drawn from Mr. Peacock's plant. It is singular that no mention is made of this variety in Williams' "Orchid Manual."

***Ansellia africana*.**—One might visit a dozen Orchid collections at this season and not see this noble African Orchid in flower; yet one cannot term it a rare species, but for some reason it is not grown successfully. At Kew, where, we believe, it receives no special attention, several plants of it are among the best things in bloom in the warm house. It is a stately growing plant having thick stems a yard or more in height, each furnished with a few long and strongly ribbed leaves and terminated by large, loose panicles of flowers which droop gracefully owing to the number of the flowers, often as many as half a hundred. The flowers measure about 1½ inches across, the sepals and petals being yellowish white heavily spotted and barred with dark brown, almost black, in fact, while the lip is of a bright yellow. It is an evergreen species and more of a ground Orchid than an epiphyte; hence, needs a substantial compost like other terrestrial Orchids. It is an old introduction and was named by Lindley over forty years ago. It is said to grow wild on Palm trees in Sierra Leone and Sir John Ansell, after whom Lindley named the genus, discovered it at Fernando Po. There are two varieties of it natives of Natal, named by Reichenbach *gigantea* and *lutea*, but these we have not seen. A third variety is that named by Baker

nilotica, which is even finer than the type, having larger and more richly marked flowers; this variety is extremely rare and we believe it only exists in the Kew collection.

***Sophranitis grandiflora*.**—For brilliancy of colour this little gem has still few equals, especially as now seen in some of the London nurseries. Another Orchid now in bloom remarkable for exceptional colour is *Ada aurantiaca*, the nodding racemes of rich orange-coloured flowers of which have a character and charm peculiarly their own.

***Cattleyas* at Chelsea.**—Amongst the best of winter-blooming *Cattleyas* which are now enlivening the Orchid houses in Mr. Bull's nursery are *C. Trianae*, of which there is almost endless variety, and all beautiful. Especially good amongst them are the forms called *vesta*, *picta*, and *alba*. Of *C. Percivaliana*, a variety called *marginata* is a decided acquisition. The numerous forms of *C. chocoensis* are also rich in colour, but, owing to the partially closed lip peculiar to this section, the brilliancy of the markings is somewhat hidden—a fault from which *C. Walkeriana* is exempt. The blooms of this, however, seem out of place at this particular season.

***Lady's Slippers* at Holloway.**—These appear to be favourites with Mr. Williams, seeing that they are grown here in such abundance. Amongst them the following are perhaps the most useful, viz., *C. insigne*, an old acquaintance, but one which still holds a foremost place as regards utility; the best forms of it are *Maulei*, *albomarginatum*, and *punctatum violaceum*. The variety of *C. venustum* called *spectabile* is also very attractive. Next comes that gem amongst Slipper-worts, *C. Spicerianum*, with chaste and prim flowers, in some instances two being upon one stem. *C. Harrisianum* appears to increase in beauty from year to year. *C. Boxalli* unites the beauties of *C. insigne* and *C. villosum*, for whilst the dorsal sepal resembles somewhat that of the former, the pouch-like lip and the peculiar varnished appearance over all put one in mind of *villosum*. Other kinds which are indispensable are the beautiful scarlet-pouched *C. Sedeni* and its equally pleasing variety *candidulum*, whilst *C. Schlimi*, with its charming white and rosy flowers, although somewhat small, is ever welcome. In the grand flowers of *C. selligerum* we have combined the beauties of *C. barbatum* and *C. levigatum*. Amongst other kinds noted here were *C. calophyllum*, *Dominianum*, *Leeanum*, *Sallieri*, and *Lindleyanum*.

***Spiranthes colorata*.**—This bright winter-flowering Orchid is probably best known under its older name of *Stenorhynchus speciosus*. It is not a common plant, nor is it one of the stock plants in nurseries, but as a beautiful January-flowering plant it is, we consider, most valuable, and as it may be grown as easily as any ordinary greenhouse plant it is the more desirable. It does not look much like an Orchid, and in an Orchid house it looks out of place. It is a dwarf plant, with broad roundish leaves of a pale green. The flower-spikes rise about a foot high, and the blossoms are borne in a dense cluster at the top. The flowers are small, but the bracts which envelop them are, like the flowers, of a pretty coral-red colour—a colour distinct among Orchids. The plant lasts in beauty for several weeks, and, being a cool-house Orchid, is none the worse for a long stay in the conservatory, or even in the drawing-room. It is easily grown, likes a fibry, loamy soil to grow in, as its fleshy roots require strong food and abundance of water during summer. There are two forms of it: one, which is considered the type, has unspotted leaves, while the variety *maculata* has its leaves blotched and lined with silvery-white markings, and this variety we think the most beautiful. It is now one of the brightest plants in the St. Albans Orchid Nursery, and also at Kew. A coloured plate of it was given some time ago in *THE GARDEN*, drawn in Sir Trevor Lawrence's garden, where it is a favourite and grown to perfection. It comes from South America.

COOLHURST, SUSSEX.

DESCRIBING Coolhurst from recollections of a June day's visit is refreshing at this dreary season. The first impressions of this delightful place as it appeared on a bright summer morning, are still strongly imprinted on the memory. The garden was then gay with colours of every hue, sweet with fragrance, and alive with the song of birds and the hum of insects. From the masses of brilliant colour the eye stole through the glades and vistas, beneath noble trees or rested on the broad expanses of lawn not yet browned by the midsummer's sun. The garden is, in every sense, in harmony with such a quiet country home as Coolhurst is. It is one of the oldest and best residences among the many sprinkled about the weald of Sussex. The caprices of modern fashion in gardening have not been followed here; you see the garden to-day probably as it existed fifty or a hundred years ago. Its present owner, Mr. C. Scrase-Dickins, will doubtless still preserve it in this state.

Here are no pretentious terrace gardens, and the only "bedding-out" is done in a little stone-edged parterre garden and quite in good taste with the rest of the place. The house is Elizabethan, not old, but the creamy white stone is so lichen stained as to give it an antiquated look, and the Welsh Poppies, yellow Fumitory and wall Ferns that grow about the crevices at the foot of the walls make the place look more venerable than it really is. The house looks well from all points, and on every side is surrounded by trees. On the front the lawn gradually slopes to the park, from

which it is separated by a Ha-ha, and so skilfully has this fence been made, that from the house one does not suspect its existence. The park falls gently to the lake, beyond which is a dense wood, chiefly Oak, and this ever-changing wood as regards colour forms a beautiful mid-distance feature. The lake view, too, is charming. Its surface was crowded with Water Lilies, both white and yellow (Nuphar), but, lovely though they are, they are apt to become troublesome weeds when they increase so rapidly, as they do here. The most interesting feature belonging to the park is the many fine Hawthorns which it contains, picturesque old trees long since past their prime, but still capable of adding great beauty to the park in May and again in autumn by means of their crops of ruddy haws. Most remarkable among them was a tree of the variety named pendula, whose branches droop on all sides, and when in bloom produce a grand effect.

The interest of Coolhurst depends much upon

its trees—not native trees, but trees introduced from every country whence we get trees. Coolhurst is probably the most richly planted estate in Sussex, and ranks with such celebrated places as Syon, Highclere, Fulham Palace, Westonbirt, and other places where foreign trees were planted extensively during the last century. The Coolhurst arboretum is probably indebted for its tree wealth to the famous "tree-planting bishop," Dr. Compton, who was related to the Coolhurst family, and who doubtless helped to enrich it. Bishop Compton was the means of introducing some of our noblest North American trees, such as the Tulip Tree, the Magnolias, the Hickories (Carya), Acers, and Thorns. The foreign trees at Coolhurst are mostly North American. Among the finest are False Acacias (Robinias), whose huge gnarled-barked stems form an interesting feature on the lawn. Among others are the Black Walnut (Juglans nigra), the Hickories (Carya), deciduous Magnolias, such as *M. cordata*

vigorous than *S. pentagyna*. Of Conifers there are, of course, crowds of fine specimens; the Canadian Hemlock Fir thrives to perfection, and so does the Californian *Cupressus macrocarpa*; *Pinus insignis*, too—trees which about London are not satisfactory. There are some very fine trees of *Cryptomeria japonica*, which appears to thrive best of all the Conifers. In the wood beyond the pleasure grounds some specimens were pointed out to me that would tell a tale in a timber yard, and it is Mr. Scrase-Dickins' opinion that this Japanese tree is one that will ultimately prove to be one of the best timber trees in this country. It is rapid in growth, is not particular as to soil, and produces excellent timber—in fact, it is one of the principal timber trees in Japan. I must stop at the pleasure grounds, though there is abundant interest in the woods around, where foreign trees have been intermixed with the native. But before I leave the trees, I must note one or two pictures I saw in

the way of hardy climbers, rambling over some of the trees. One was the Traveler's Joy, running over an Evergreen Oak, festooning it in a most charming way. In September when in bloom, and later when in feathered seed, one can imagine the effect of it. Another, and perhaps the prettiest flower picture I saw here, was the *Clematis montana* running over a roof of one of the out-buildings, completely smothered with its starry white blossoms. From the roof the rope-like branches leapt to a Portugal Laurel, which it garlanded in the same beautiful way. A hint I got from this sight was that this *Clematis*

Coolhurst, from above the lake. Engraved for THE GARDEN from a photograph.

and acuminata; Snowdrop Tree (Halesia), Amelanchiers, Persimmon (Diospyros), all of which are represented by old trees. Among foreign European trees, none are so conspicuous as the Evergreen Oaks, which thrive well in this part of Sussex, and help to give the gardens a snug winter aspect. The Silver-leaved Lime (*Tilia argentea*), a Caucasian tree, is one that is seldom seen, but at Coolhurst it is a first-rate tree. When there, a slight breeze upturned the leaves and showed their silvery under-surfaces, as it did also those of the *Pyrus vestita*, whose leaves are likewise of silvery whiteness beneath. One of the rarest shrubs here is *Stuartia pentagyna*, a most beautiful North American plant, that bears white flowers as large as those of a Camellia. This *Stuartia* must have been planted many years ago, as it is now a small tree, perhaps as large as ever it grows. The other *Stuartia*, *S. virginica*, and its near relative, *Gordonia pubescens*, exist, I believe, in the Coolhurst arboretum, but are less

likes a north aspect, for on that side the branches were thickest and the flowers most profuse, though the plant was growing in a border on the south side. Before an exotic tree was planted at Coolhurst, and perhaps before a residence existed there, the spot must have been remarkable for native trees, for finer specimens than exist in this place could not be found in Sussex, a county remarkable for fine trees and woodlands. Beeches are the prevailing trees, and some ponderous specimens stand out on the lawns, their wide-spreading limbs overhanging the walks and making charming shady glades through which the brilliant tints of Rhododendrons and Azaleas in the distance are intensified. Fine, however, as are the Beeches, the Oaks are still more remarkable, especially as regards size. Other native trees which arrest the attention of the tree-lover are the fine groups of Scotch Fir, bonnet-headed in many cases; the old Birches, those by the lake being particularly beautiful; Sycamores, which

in the park are of great size; Yews, which are invaluable; the Mountain Ash; and among rarer kinds the Wild Service (*Crataegus terminalis*), of which there are some remarkable examples. These are dotted about and grouped in a variety of ways, some of the groups being most picturesque mixtures of deciduous and evergreen trees, each allowed to grow at will.

The glory of Coolhurst in early summer is most certainly the arboretum, which is crowded with American shrubs of every kind, and which grow in the greatest luxuriance. From the middle of May till the end of June the place is lit up with brilliant colour such as can only be obtained in open-air gardens by means of shrubs, such as *Rhododendrons* and *Azaleas*. When there in June last the place was aglow with the fiery tints of *Azaleas*, and the air seemed filled with their spicy fragrance. Instead of the stunted dwarf *Azaleas* with which one usually meets, you see here bushes 7 feet or 8 feet in height with wide-spreading branches, the flower-twigs of which are arranged in tabulated tiers, which is the natural growth of these shrubs, as described by those who have seen them in the swamps and shady woods of North America. It is difficult to account for the great luxuriance of the *Azaleas* and *Rhododendrons* here. It may be the soil, which is loamy, but most probably it is the genial, moist climate experienced in this part of Hampshire which seems so favourable to the growth of exotic trees and shrubs. The whites, yellows, scarlets, and pinks of these *Azaleas*, seen in association with greens of different shades, seemed to me to be the most gorgeous floral sight one could imagine or expect to find in an English garden. There is a prevalent idea that hardy *Azaleas* will not succeed in shade, but a visit to Coolhurst would soon convince one that such is not the case; indeed, they seem to thrive as well here as in the famous peat gardens of Surrey.

The *Rhododendrons* are quite as remarkable as the *Azaleas*, but in some way lack the charm which the latter possess. They are grand certainly, but they have not the elegant and picturesque growth which belongs to the *Azaleas*, though when allowed to grow as they like, as here, they become less formal and lumpy. In some parts of the pleasure grounds and adjoining woods there are long vistas of *Rhododendrons* 10 feet or 12 feet high, and their effect when in flower may easily be imagined. Besides ordinary hardy *Rhododendrons*, Mr. Scrase-Dickins has planted out several Himalayan species supposed to be only half-hardy, but here they appear to be quite acclimatised. For instance, there are great bushes of such kinds as *R. campanulatum*, *R. Thomsoni*, *R. niveum*, and *R. arboreum* growing as vigorously as the Pontic and Catawba hybrids. The evergreen growth at this place consists mainly of *Rhododendrons*, but all kinds of so-called American shrubs help to enrich it. During winter, *Andromedas*, *Vacciniums*, *Pernettyas*, *Zenobias*, *Kalmias*, either form little groups by themselves, or are made to intermingle with the *Rhododendrons* and *Azaleas*. In *Azalea* time the *Kalmias* were only in bud, so that the flowering season of such shrubs extends to midsummer. Another noteworthy shrub of the Heath family is *Gaultheria Shallon*, which has become quite naturalised in the woods, and a capital undergrowth it makes; probably it would make excellent game covert if one could get enough of it.

The white Chinese *Azalea* (*A. indica*), common enough as a greenhouse plant, has become perfectly acclimatised here. Some years ago Mr. Scrase-Dickins planted out a few bushes of it by way of experiment; these have proved to be quite hardy; they grow most vigorously, and not only

grow, but flower profusely. Those who have spare plants of this white *Azalea* would do well to boldly follow this example, provided, of course, that they are south of London and in a sheltered locality. The little *Azalea amena* is also planted out here, but this is generally known to be hardy enough to stand our winters out of doors.

In the conservatories and greenhouses one may find many out-of-the-way plants, as in the case of the open-air trees. In the conservatory attached to the house are several rare climbers, most beautiful of all being the old *Bignonia Chamberlayni*, which also enjoys the more modern name of *Anemopaegma racemosum*. It is extremely handsome in flower. In shape and size the blossoms resemble those of the hardy *Bignonia grandiflora*, and are borne in clusters of half-a-dozen or so. They are of a soft primrose-yellow, an uncommon colour among greenhouse climbers. It was shown a few weeks ago at South Kensington, where it was recognised only by a few as an old favourite which has dropped out of general cultivation. There is also in this house the graceful and bright-coloured *Cantua dependens*, another climber once much grown, but now confined to comparatively few gardens. Commoner climbers, such as *Taesonnia Van Volxemi*, also festoon the roof, and one may see the choice white variety of *Daphne indica* growing uncommonly vigorous. It was from this conservatory that the specimens came of this white *Daphne*, from which the plate for THE GARDEN was prepared some time since. The kitchen garden is one of the old-fashioned kind, substantially walled in with borders of hardy flowers, and containing the usual complement of plant and fruit houses. There is a capital collection of Orchids, among which there are fine specimens of good old kinds, which now-a-days fetch fancy prices. The present gardener, Mr. Kemp, who was with the late Mr. Cunningham, of Orchid renown in Scotland, is well known to be one of the best Orchid growers in the country, and, being quite an enthusiast, takes a pride in the collection, and in pointing out to visitors the choicest specimens. There were many in bloom when I was there, though the full flush of the Orchid flower season was on the wane. In the entrance-hall of the house there was a grand specimen of the rarely seen *Cattleya lobata*, bearing three spikes, and fourteen flowers altogether. It had been in the hall six weeks, and Mr. Scrase-Dickins assured me that this protracted stay in the house in summer did not materially affect the health of this or many other Orchids. I much admired, too, the handsome vases in the hall and drawing-room, containing untrained specimens of Indian *Azalea*—great bushy plants, informal in outline, yet not untidy-looking, and smothered with bloom. The prim training which gardeners practise on Indian *Azaleas* quite spoils their natural growth; they are not to be compared in beauty to untrained specimens. It is satisfactory to see that a collection of bulbous plants is likely to become one of the specialities of Coolhurst, and it is to be hoped that Mr. Scrase-Dickins will become a second Dean Herbert among bulbs. He seems to be particularly fond of them, and he is continually adding to his already rich collection. Being secretary to the Daffodil committee, he has acquired a deep knowledge of Narcissi, and he ought to grow a representative collection of them. Another speciality at Coolhurst is single *Camellias*, of which there is undoubtedly the finest collection of seedlings in Europe. A plate of a few of these appeared in THE GARDEN last year, and at the time Mr. Scrase-Dickins told us all about them. W. GOLDRING.

Christmas Roses.—I am profoundly ignorant of *Hellebores*, but find in a note-book the following description of a flower which I noticed in North Italy last March. Perhaps

Mr. Archer-Hind or someone else will kindly say to which variety it is to be referred. I fear I made no note of stem or leaves, which seem to be necessary criteria of *Hellebores*. "Between Menaggio and Porlezza (Como-Lugano) fine, strong-growing *Hellebore*: flower large and cupped, pure white, with slight flush of buff-pink. Noticeable for its pink stigmatic and tufted yellow anthers."—G. H. ESCLEHEART.

NEW PLANTS OF 1886.

THAT the year which has just closed has not been in any way behind its predecessors in the production of new plants is sufficiently evident by a glance at the long list of flowering and fine-foliaged plants that have been certificated by the Royal Horticultural and Botanical Societies. Certain sections, such as Orchids, stove and greenhouse plants, and ornamental foliaged plants have been well maintained, and the production of good Ferns has also been above the average; hardy herbaceous plants have also received some valuable additions.

Among flowering plants adapted for greenhouse culture, *Amaryllises* occupy a prominent position. *Her Majesty* is a bright crimson flower of large dimensions and of good substance and shape, veined with a deeper hue; *Crown Princess* of Germany produces large and perfect flowers, the ground colour of which is white, feathered and striped with scarlet; it is very distinct and robust in habit. *Duchess of Albany* is dark crimson, ornamented by a pure white band in the middle of each petal; *King of Crimsoms* is a vivid coloured flower of excellent form and substance, and well worthy of a prominent place in every collection, notwithstanding the fact that it is of smaller dimensions than those of most of the others described. All these *Amaryllises* belong to that class which flowers from March to June. The autumn-flowering kinds, which form a class entirely distinct, comprise such grand varieties as *Mrs. Lee*, *Autumn Beauty*, &c., all offshoots from the old-fashioned *A. reticulata*. *Lady Mayoress* produces abundantly in November large, perfectly shaped crimson flowers, ornamented by reticulations of the same colour, each segment being further adorned in the middle by a broad band of pure white.

Amongst *Begonias*, the tuberous section is by far the most popular, but other kinds possess, for the most part, the advantage of flowering during autumn and winter. To the latter class belong *B. Imperial*, a variety which bears large flowers of great substance and of a lovely shade of crimson; *B. Marchioness of Lorne*, a pretty cerise-coloured sort; and *Louis d'Or*, a beautiful yellow; these are three of the best single-flowered kinds. Among double sorts brought out during last summer may be mentioned *B. magnifica alba plena*, a grand creamy white; *B. Queen of England*, a beautiful full flower of a bright salmon tint; *B. Paul de Vieq*, a lovely variety of a peculiarly soft, rosy colour; and *B. Mrs. Plunket*, a plant of extra good habit, and with remarkably well-formed flowers of a blush and buff colour. Amongst autumn and winter-blooming sorts *B. rosea gigantea* is a very good variety. It forms compact specimens, which in autumn become completely covered with brightly coloured flowers. By far the best of last year's production is, however, *John Heal*, an interesting kind, the result of crossing *B. socotrana* with a tuberous and summer-flowering variety. It partakes of the qualities of both its parents. Like *socotrana*, *John Heal* blossoms late in autumn, and the influence of the tuberous parent is manifest in the flowers, which are of a bright rosy colour, and produced in long, slender, and particularly graceful racemes, each bearing from six to ten blooms. In a cut state these last for a considerable length of time, varying from fifteen to twenty days. Another good addition to the genus is *Arthur Mallet*, a *Begonia* of Continental origin, and decidedly an acquisition. It is a hybrid between one of the numerous forms of *B. Rex*, with chocolate-coloured foliage, and a tuberous or summer-flowering kind. It is bushy in habit, and grows to about 18 inches in height. Its leaves are elongated and heart-shaped and

brilliant in colour, and the flowers, which are produced in abundance, are also very attractive.

Rhododendrons of the javanicum section may be said to be amongst the best plants grown for the decoration of our glass-houses, and although most of the hybrids from it flower at all times of the year, they are particularly showy at this season. They can be used to brighten up our conservatories and intermediate houses, for they generally produce their best flowers between November and February. They are also equally useful as cut flowers for bouquets, in which, on account of their long, slender tubes, they may be used with advantage. Among single-flowering varieties brought out this season, Queen of Yellows is undoubtedly the most striking. It has yellow, or rather fawn-coloured, flowers of good size and of perfect form and substance, borne in large trusses, each consisting of nine or ten flowers; and the habit of the plant is excellent. Rose Perfection, luteo-roseum, and amabile are all improvements on known varieties, the plants being good in habit, and the flower-trusses large and pleasing in colour. Rajah, belonging to the bal-amiflorum group, is, however, the best amongst these Rhododendrons. It is a robust grower, and produces very double flowers of a rich, warm apricot colour, flushed with red, the outside petals being much larger than those inside; the tube is much shorter than that of other kinds, and the flowers expand widely.

In Gloxinias we have this year had some notable improvements. Ivanhoe is a dark purple, edged with white; Vestal, a good-sized white-ground flower, with a faint rosy bordering. In addition to these there are also three beautiful self-coloured varieties, viz., Irma, brilliant scarlet; The Moor, rich purple; and Ormende, velvety crimson. All the kinds here enumerated belong to the erect-flowered type.

Other stove and greenhouse plants consist of Fuchsia triphylla, a species entirely different from all other Fuchsias in cultivation. Its name is derived from the arrangement of the leaves, which are in threes on the branches. It forms a dwarf, bushy plant, which is remarkably floriferous, and its flowers, which are bright scarlet, and which measure about an inch in length, are disposed in loose clusters, which terminate nearly every shoot. Cyrtanthus hybrida rosea is also an acquisition. It flowers in autumn, and is the result of a cross effected at Burford Lodge between the lovely old-fashioned Vallota purpurea and Gastronema sanguineum. The flowers of young plants of it are variable in colour, and also in size. Clerodendron nutans and Beaumontia grandiflora, though by no means new, are so very seldom met with nowadays, that when seen in such good condition as they have been this season they well deserve special notice. The Clerodendron is a strong-growing stove shrub, whose shoots are furnished with terminal, pendulous clusters of five-petalled white flowers, with a light brown calyx. Its foliage is also very peculiar, being strap-like, about 5 inches long, by 1½ inches wide. It is a shrub which flowers in summer, and well worthy of special attention. Beaumontia grandiflora was formerly grown in our gardens, where its large, trumpet-shaped flowers, resembling those of a Datura, were very ornamental. It is a plant deserving of much more attention than it receives.

To Orchids some valuable additions have been made. Foremost, perhaps, among imported species is the curious and beautiful Cypripedium Sanderianum, which in form and general appearance possesses some resemblance to C. levigatum and C. Robellini. The flowers are in size about equal to those of C. levigatum; they have two narrow purplish brown petals prolonged into long tails; the lip is also long and of an olive-brown colour, with a long compressed stalk, and with the column provided with a very long staminode in form of a spade. A plant of it, which was shown, only bore one flower, but some dried specimens show as many as six on one spike. In Habenaria militaris we have a wonderfully pretty terrestrial Orchid, surpassing in brightness even the gay Sophronitis grandiflora itself. It is an

entirely new species collected in Cochin China by M. Rognier, and is a valuable addition to autumn-flowering Orchids. Unfortunately, it is terrestrial and deciduous, and, therefore, slightly at a discount with some who are afraid of not seeing it turn up again after its resting season. In habit it resembles our native kinds, with this difference, however, that its foliage is tinged all over with light greyish purple; the stems grow to about 15 inches in height, and bear from twenty to thirty flowers, whose shape greatly resembles that of an Impatiens, provided, as they are, with slender green spurs, but their colour is brilliant scarlet. Catasetums are, as a rule, not favourites with Orchid growers; but in the new C. Bungei we have undoubtedly a fine plant worthy of special attention. Its large ivory white flowers, six or eight in a raceme, are of a fleshy character, and curious in shape on account of the lip, which is pure white, being cordate in front, with a round cavity at the base, lined with orange-yellow. When it is stated that the individual flowers measure upwards of 4 inches across, it will be readily understood that this new Catasetum is at once the most interesting and the largest representative of this singular genus. Dendrobium stratiotes, a new species from North Australia, like the preceding, was discovered by one of Mr. Linden's collectors, who states that it is the most remarkable Orchid which he has found in his travels, and that in its wild state it is so floriferous, that on a plant with ten bulbs he has counted as many as 250 flowers all expanded at one time; frequently, he says, fifty flowers may be found on a single bulb. If equally floriferous under cultivation, this new Dendrobium cannot fail to become a general favourite. Its flowers, which have a white ground colour, have petals and sepals suffused with pale green, and the pure white lip being striped with bright carmine, renders it highly attractive. In Cypripedium callosum we have also a new species brought home from Cochin China by M. Rognier, who found it growing by the side of rivulets with its roots in water. It possesses much of the general appearance of C. Lawrenceanum, a most extraordinary thing, seeing that it comes from an entirely new locality. In details, however, it is very different. The dorsal sepal of its large and well developed flower is the most characteristic feature, being marked on a light ground with radiating lines of a deep purple tint, and it is further ornamented by a pure white margin of about half-an-inch in width. Although not so deeply marked as that of C. Lawrenceanum, its foliage is also very handsome. Cyrtopodium Saintlegerianum is a showy Orchid; its stems, which are cylindrically pressed, are about 5 feet high, and are furnished with leaves plicately veined. Its flower-spikes, which are about 2 feet long, are branched at their upper part, and covered with orange flowers spotted with brown. Among what may be termed accidental importations, the most meritorious varieties of already existing good species are, amongst Cattleyas, C. Eldorado virginialis, Triane Schrederiana and Russelliana, C. Mossie splendissima and Arnoldi, and C. Mendeli Duke of Marlborough, whose large and massive flowers have petals about 3 inches broad, delicately tinged with purple. The lip, which is veined in the throat with yellow, and which has its apical portion of a rich crimson tint, which also runs round the margin, measures fully 2½ inches in breadth. Several handsome forms of the beautiful Odontoglossum luteo-purpureum have also made their appearance among recent importations. O. vexillarium Sunrise is undoubtedly the most distinct of the several forms of that popular Orchid. It is, in fact, the one which shows, to some extent, a new departure worthy of the name. It is altogether a most beautiful flower, with a deep rose-coloured lip; the petals and sepals are white suffused with rose, and the eye, which, as in the type, is yellow, is surrounded by a ring of white. In Cypripedium Hycanum we have an admirable form of C. Lawrenceanum, and one of the most distinct Lady's Slippers known. This variety is entirely devoid of the purple tinge characteristic of the species.

In shape and size, both flower and foliage are very similar to those of the species, but the dorsal sepal is pure white lined with green, and the pouch is also light green. Saccolabium curvifolium album is a good white form of that lovely species, although its flowers, which are pure white, are rather small. In that deservedly favourite genus Odontoglossum we have some excellent plants to add to the already existing list. O. Pescatorei Vervaeckianum is one of the most striking forms of that species. Its flowers are prettily spotted, of medium size, and when only partially opened very conspicuous, owing to their bright red colour. Amongst varieties of O. crispum or Alexandro, the one known as Knox's variety occupies the most prominent position. Its petals and sepals, which are particularly broad, although white at the base, are mainly yellow, and ornamented by a few brown spots which cross them about the middle. Then there are the beautiful forms named O. apiatum, Imperati, Mrs. Dorman, and Hrubyanum, the latter only comparable with such gems as O. Veitchianum and Sanderianum. A very curious and equally beautiful plant made its appearance under the name of Dendrobium crassinode Wardianum, supposed to be a natural hybrid of that very popular species. The flower-spike of this plant, which originated amongst an importation of D. Wardianum, was fully 3 feet long, and two-thirds of its length was clothed with flowers, white in parts, with the lip, sepals, and petals tipped with pale rose, the interior of the throat being orange; on the base of the lip are also two crimson spots. These flowers, which are intermediate between those of the supposed parents, are disposed in clusters of three at the nodes, which are as prominent as in D. crassinode. As a natural hybrid, too, Laelia lilacina opens up a wide field for conjecture. It is supposed to be the result of a natural cross between Cattleya crispa and Laelia Perrini. The same cross with Mr. Doiny produced L. Pilcheri. The new comer was found in an importation of L. Perrini in 1883. Its scape is usually twin-flowered; the tube of the flower is white, the interior being marked with purple; the lip is also white, and is adorned in the middle with a purple blotch, while the sepals and petals are pale lilac. The flowering time of this singular plant is intermediate between the periods of flowering of the two supposed parents. A curiosity which made its appearance on the Continent is named Calanthe Veitchi rosea alba. Its flower-spikes in size and habit resemble those of C. Veitchi, but they are covered with flowers, some of which are rosy pink, others white, and others again partly white and partly pink. This curiosity, it appears, found its way to Europe amongst an importation of Limnites rosea.

Of home-raised hybrid Orchids, of which the parents are known, two highly interesting subjects have flowered during last season. These are Phalanopsis intermedia and Laelia Batemaniana. The former is the result of a cross effected by Mr. Seden between P. rosea and P. amabilis, with a view to demonstrate clearly that the plant which formerly was imported under that name owed its origin to these two parents; and we must say that the result of the artificial cross leaves no doubt as to the correctness of this supposition, for the flowers of Mr. Seden's plant have all the characteristics of those of P. intermedia; the petals and sepals are white, the former tinged with crimson at their base; the central and lateral lobes of the labellum are purplish crimson, ornamented with a few dots and a yellow crest. The flowers of the seedling plant measure about 2 inches in diameter, and the foliage of the young plant is the same as that of a robust P. intermedia. Laelia Batemaniana is the result of a cross also effected by Mr. Seden between Cattleya intermedia and the charming dwarf, bright-coloured Sophronitis grandiflora. Its mode of growth is very similar to that of the Sophronitis, but the leaves and bulbs are larger, and the former are produced in pairs. In general aspect the flowers resemble those of the Cattleya parent, and they are nearly of the same dimensions, but there is a great alteration in their

form, and a greater still in their colour; the petals and sepals partake of a tint peculiar to *Odontoglossum roscum* or to *Mesospindium vulcanicum*. The lip bears a close resemblance to that of the *Cattleya* parent; its upper part is white, and the anterior lobe of a beautiful violet-crimson. The whole plant when in flower only measured 4 inches in height, but the bulbs as they are produced in succession appear to gradually gain in strength. Several other home-raised seedlings have also shown themselves during last season, conspicuous among them being the charming *Cypripedium Tautzianum*, a very pretty hybrid, raised between *C. niveum* and *C. barbatum*; also, *Zygopetalum leopardinum*, *Calanthe hybrida*, a strong grower with white flowers; *Masdevallia glaphyrantha*, with small flowers of a dull, purplish crimson colour, and furnished with tails about 2 inches long, and tipped with yellow; *Dendrobium micans* is a lovely hybrid, raised between *D. Wardianum* and *D. litiflorum*. Its flowers, which are of a waxy texture, like those of *D. Wardianum*, measure over 3 inches across. The sepals and petals are mauve-purple, becoming paler towards the base. The lip is nearly similar to that of *D. litiflorum*. It is white, with a large maroon-purple disc, and a rose-purple blotch at the apex.

Ferns now this season possess some good qualities. The most prominent among them is undoubtedly *Nephrolepis rufescens triplinatifida*, a beautiful plumose form, whose fronds, which frequently attain from 30 inches to 35 inches in length and 4 inches in breadth, have the appearance of ostrich feathers, owing to their massive character and their sides being beautifully curled. There have lately been many forms of *Nephrolepis*, some depauperated like *N. Duffi*, some regularly crested, like *N. davallioides furcans*, but none in any way comparable with this new comer. Its fronds, which are produced abundantly, are of a lovely pale green, and sufficiently strong to hold themselves up without any support, notwithstanding their great weight. Like all other kinds of *Nephrolepis*, it grows freely, but requires stove temperature. In *Davallia retusa* we have an elegant stove Fern, a native of Sumatra. It is pendulous in habit and free in growth, and therefore well adapted for growing in hanging baskets. The fronds, when fully developed, measure from 30 inches to 35 inches in length. The pinnules are of peculiar form, though some of them, especially those towards the extremities of the pinnae, are triangular; they are light green, and contrast prettily with the pale crimson tint of the stipes and rachides. *Davallia solida major* is a Fern with bold deltoid fronds, tripinnate, leathery in texture and massive in appearance. *Gymnogramma gloriosa* is a wonderful improvement on *G. schizophylla*, which it is destined to supersede, being of much freer growth, and producing fronds not only of much greater dimensions, but in such large quantities as to make it hard to believe that it is merely a variety of that milky-growing species. To the genus *Adiantum* several good additions have been made. *A. Birkenheadi*, for instance, is totally distinct in aspect from that of any other *Adiantum* known. It is compact in habit, notwithstanding the long and slender character of the stipes, the whole frond measuring about 2½ feet long; its open ramification gives it a handsome appearance, and its bright deep green colour greatly enhances its beauty. *A. fragrantissimum* is also a very good plant, and among the several varieties of *A. Capillus-veneris*, the form called *imbricatum* is, without doubt, the most striking. It is somewhat related to the Cornish variety, called *cornubiense*, but the pinnae are much larger and deeply divided, or markedly fringed on the margins; the fronds, being, moreover, broad and dwarf, impart a particular massiveness to the plant. In the genus *Pteris* are also produced some good novelties. *P. tremula foliosa* is a grand improvement on the already popular Australian species; it is a stately Fern, which attains in a short time twice the size of the type; its fronds, which are of a delicate pale green, are elegantly and effectively crumpled, and have thus a very

plumose and massive look. We have in Naylor's crested variety of *P. serrulata* a densely bushy plant, which, in fact, has all the appearance of a very finely-cut tuft of sea-weed; it differs essentially from anything known, as the fronds are upright, stiff, and measure about 7 inches in height. By far the best, however, of all the variations which have taken place in the genus of late is *Pteris Mayi*, which may be summed up as being a very good crested form of *P. cretica albo-lineata*, the lovely variegation of which it has retained; but it is of a greatly improved habit, as barren and fertile fronds are all of the same size. It will certainly prove to be an excellent plant in every way, being a free grower and comparatively hardy. It is not often that we have to note novelties among Filmy Ferns likely to become popular, but we have this season in *Todea grandipinnula* a handsome Fern of remarkably free growth, and which can successfully compete with such favourites as *T. superba* and *T. hymenophylloides* or *pellucida*. The fronds of this variety are very massive in appearance, and this singular leafy development gives the plant an aspect totally different from that of any other known species or variety of *Todea*. It is a plant which fully deserves good cultural care. There are also a couple of new *Selaginellas* well worthy of a place in all collections: one is *L. tessellata*, a handsome species with erect quadrangular branches and flat deltoid fronds. The most distinct, however, is *S. gracilis*, a species from the South Sea Islands, belonging to the same section as *S. Wallichi*, *Victoriae*, and *Lobbi*, from which it is, however, entirely distinct. Like these, it has sub-erect stems, which are slender, cylindrical, and furnished with dark green cuspidate pinnules that become gradually shorter as they approach the apex of the pinna. In habit it is umbrageous and particularly dense, seldom attaining more than 15 inches in height.

Amongst fine foliaged plants the most striking are the following, viz., *Phrynium jucundum*, a Maranta-like plant from Java, with long-stalked leaves lanceolate in form, and produced abundantly from underground rhizomes, forming quite tufted masses of foliage of a bright green colour variously marked with white stripes of different widths running longitudinally. *Maranta eminens* is another excellent addition to this lovely genus. This new species has stalked, oblong leaves having a greenish cream-coloured ground, on which are scattered some transverse, oblong blotches of deep green of different sizes, and sometimes connected with the midrib. In *Paliourea jugosa* we have a stove shrub with handsome foliage of a deep velvety green colour, ornamented by a lilac midrib. *Aphelandra chrysops* is a valuable acquisition. Like most of the species with which we are acquainted, it may be grown for its flowers and bracts, which are of a beautiful yellow, as well as for its foliage, which is marked on the lines of the main ribs with creamy white. We have in *Trevisia palmata* a distinct and very ornamental Araliad, with spiny stem and deeply palmated seven-lobed leaves of great substance and of a cheerful green colour. All the foregoing require stove temperature. In the greenhouse section we have the charming little *Oplismenus albidus*, a dwarf variegated Grass like a *Panicum*, with foliage 1½ inches long and acutely pointed. The ground colour is white, with a green band running longitudinally through the middle of the leaf. It is a little plant which will be sure to be appreciated by everybody, as its usefulness becomes more apparent every day. The only new Palm which is likely to prove really useful is *Phoenix hybrida*, a kind which shows, in quite a young state, its characteristic slender recurving leaves with long, narrow pinnae. It is very graceful, though compact in habit.

Two hardy plants with pretty foliage have made their appearance this season. One is a fine showy border plant, with white banded foliage and good habit. It is called *Hemeroallis Kwansoi foliis albo-variegatis*. The other is *Ulmus Petersi pendula*, a distinct-looking Weeping Elm with long, slender, pendent branches, clothed with

alternate rough leaves, peculiarly crumpled, and with coarsely toothed margins.

Amongst *Chrysanthemums*, the Japanese section still commands the greatest attention. Foremost among them is *White Ceres*, so named on account of its being a sport from a plant under that name, yet the flower of this new form, which is of a delicate blush tint, is so different in build from that of the type, that it appears hardly possible it should be a sport from it. *Coquette de Castille* is large and full flowered and of a soft rose colour; the florets are tubular, narrow, and slightly reflexed. *Phœbus* has bright yellow flowers, of medium size, and very double—a dense mass, in fact, of long, narrow florets. *Buttercup* is a beautiful full, reflexed flower, and the brightest yellow yet raised; it is finely formed, and particularly rich in colour. *La France* is wonderfully rich in colour, a sort of crimson-purple, quite uncommon; the flowers are of medium size, dense, and of good form. The Pompon class, which contains some remarkably pretty flowers useful for bouquet-making, is represented amongst novelties by a couple of very good things, such as *Flambeau Toulousain* and *Mlle. Elise Durdan*. The former produces in abundance small, compact, globular flowers with quilled petals, of a deep rose, edged with white. *Mlle. Elise Durdan* is a pretty quilled, deep lilac, perfectly globular, and very regular in form. It is altogether one of the most pleasing of Pompons.

*Dahlia*s of all sections have received additions. Single forms are well represented by *Mr. Rose*, a white ground flower profusely striped with lake. *Zephyr* is quite distinct and novel, medium in size, and of a lovely orange-crimson, distinctly margined with yellowish buff. *Miss Limaker* is a rosy crimson flower, with the exception of a golden yellow ring which surrounds the disc. To the Cactus section has been added *Yellow Constance*, a kind which produces bright yellow flowers with straight and fluted petals; but the best variety in this section is undoubtedly *Empress of India*, whose double flowers resemble those of a form of *Paragon*. It is one of the most beautiful and distinct varieties yet produced. Its colour is rich claret-purple, streaked with red. Among new decorative kinds *Annie Harvey* stands in the foremost rank on account of its colour, which is blackish crimson, flushed with scarlet; the flowers are medium-sized, double, and very handsome. Amongst Pompon and fancy varieties, *Eccentric* and *Valentine Humphries* are the most remarkable. The flowers of the former are peculiarly marked with orange and crimson, colours which vary in each flower. Those of the latter variety are rather large and perfectly shaped. They have a salmon-pink ground colour, copiously striped with bright crimson.

Amongst other subjects, new *Gladioli* have been plentiful this season. The most striking are *Lord Salisbury*, a kind with deep crimson purplish throat, and segments flamed with dark crimson; *Empress of India*, a lovely white ground flower, profusely feathered and also suffused with mauve. This variety produces very large spikes furnished with flowers of unusual size and substance. *Clarence* has flowers striped with maroon on a crimson ground colour, and particularly velvety in texture and large in size. Among varieties obtained by *M. Lemoine* may be mentioned *Voltaire*, a deep cerise with spottings of yellow on the three lower segments; *La France*, light rose and dark crimson; *Septre d'Or*, primrose with brown-crimson spots in the throat; and the curious *Sanderi*, bright scarlet, spotted like a *Tydea*. Among arborescent *Pæonies*, *Purity*, a variety with single pure white flowers, is a very effective plant, as is also *liacina*, whose white flowers have the base of their inner petals adorned with deep crimson blotches; *Madame Lafay* produces very large double flowers, some of which measure 9 inches in diameter, and being bright rose-coloured with a broad margin of pale pink they are particularly attractive. One of the finest *Pæonies* yet raised is, however, perhaps *Reine Elizabeth*; its flowers are very double, of

excellent form and substance, and their colour is a deep rose-scarlet. The herbaceous kinds are well represented by Queen Victoria, Festiva maxima, and Eclair, all varieties of great merit. Amongst Hollyhocks, which, owing to disease, are not cultivated so extensively as they used to be, may be noted such improved forms as Revival, a creamy yellow, well-built flower, and Shirley Hibberd, a crimson variety, large and full, with guard petals distinct and prominent. In *Crataegus tatarica* we have a most valuable addition to our Thorns, as its foliage is large and robust, and its bright crimson haws, as large as Black Heart Cherries, are produced in great abundance. S.

FRUIT GARDEN.

THE ORCHARD.

THE weather at the present time is wintry in the extreme, the heavy fall of snow, resembling half-melted ice, having weighed down the trees, and put an end to all bush-pruning, at least for the present. Weather like this, although seasonable, is by no means agreeable, especially to those who, through force of circumstances, have been unable to push on with their pruning and training when mild days lent their aid to progress. Knowing the advantage of taking time by the forelock, many fruit growers will have broken the heart of this chilling work, at least as far as it is prudent to go with wall and garden trees generally, and will now be able to turn their attention to standard orchard trees, for which I have so often pleaded, and, judging from signs of progress, I believe not in vain. Still, there is plenty of work crying for hands as loudly as interlaced branches can speak, and this is just the time for giving relief. Planting, as a matter of course, is laid aside for the next six weeks, if not for the season, as no one who understands his business cares to remove trees in mid-winter, be the weather ever so favourable; but the roots of old friends may be looked to in more ways than one. First of all, heavy land should be well drained, otherwise the application of manure and top-dressing will fall useless, if not injurious, as the roots resting or rotting in cold, stagnant water cannot assimilate the food given to them. This, then, is the foundation on which the superstructure of successful culture must rest, and the sooner it is carried out the better, for we may as well look for Figs from Thorns, as bright handsome Apples from waterlogged orchards. I have often pointed out how the clay or marl from the bottoms of the drains may be turned to profitable account by burning with the old stems and branches of the trees, and I would remind the superintendents of old plantations that they need not fill in the drains as soon as they are opened, as exposure facilitates the escape of water from the land and pulverises crude soil if left lying on the surface until dry weather sets in in March. Meantime, stones, rubble, anything that is open and porous, may be collected and shot in over the pipes with

the greatest advantage. Another operation which should always follow draining is top-dressing with fresh soil, bone dust, or a well prepared compost, consisting of manure, road-scrapings, the scourings of ditches, and plenty of charred refuse. This need not follow closely upon draining, but an eye should always be kept on every load of fresh material that will swell the store heap, without which points gained cannot be retained. Meantime the weather continuing unfavourable for other work, pruning and cleansing should be pushed on with vigour. The best pruners do not open the heads of neglected trees suddenly or check the roots by the removal of large limbs the first season, but open out the centres to let in light and air, and allow the completion of the work to extend over two or three years. Many people scrape the stems and strongest branches before they apply lime and other washes, and where the time can be spared this is a short cut to the attainment of the object held in view. But scraping the stems of a number of large trees is a heavy item, and I have found that syringing with soapsuds, lime water,

introduce it with young trees or grafts. Dipping or washing the young trees or scions as soon as they are received is a brief and simple operation which should never be neglected, as it may destroy the forerunners of a colony of the most persistent insects met with in Apple orchards.

THE GARDEN ORCHARD.—From the farm to the garden orchard is but a step, yet the two modes of management are quite distinct, and for this reason a few words here may not be out of place. The garden orchard is generally managed by a man who is well up in the art of root-pruning, and his trees, after the July pinching or winter pruning, are models of form and neatness. But the question arises, Is this close pruning an advantage, or otherwise? I maintain that it is a disadvantage, as many strong-growing varieties positively refuse a return that will pay for the labour; whilst all, be they strong or weak, become worn out by the time an extension-trained tree arrives at its best. One of the best planted garden orchards with which I am acquainted was established in an adjoining county about five and thirty years ago, and the trees were about twelve

years old when I first saw them. Each tree—a dwarf—had been carefully trained to ten or twelve shoots, starting from near the ground. By means of stakes and ties the external branches took a horizontal direction, and then grew upright, or nearly so, to the height of 10 feet or 12 feet, and were kept closely pruned to two eyes like so many cordons. The fruit, so long as the trees were extending, was excellent, and carried first prizes wherever shown, but, having filled their allotted space, restriction was the course decided upon, and from that day to this the trees and fruit have been going rapidly down the hill. Had every alternate tree been grubbed up to make room for its neighbour, the result might have been different; but annual or biennial root-pruning—no trifling business—fell into anear; the balance was lost, and canker followed. Having myself a row of hand-

Coolhurst. Engraved for THE GARDEN from a photograph. (See p. 21.)

some pyramids of Cox's Orange Pippin, from which my pruner made the small timber fly every winter, much against his will I decided upon extension training, as the fruit did not pay. The trees, well washed each winter with soapsuds, are bright and clean, and now bear good crops of fruit. If practical lessons are worth anything, I would advise owners of hard pruned pyramids and bushes to give them more room, either by transplanting or cutting down every alternate tree, and to allow the branches of those left to extend. Straight-stemmed pyramids, it is true, are difficult subjects to commence with, but once the centres are taken out and the lateral branches are well thinned and allowed to extend, the change which takes place in the course of two or three years is agreeably surprising. Such trees, it is hardly necessary to say, must not be allowed to grow wild, but root-pruning, once the roots are lifted and re-laid in a horizontal position, will not give much trouble, and heavy winter pruning will be.

or weak brine answers equally well; or, lacking the convenience, newly-slaked lime cast into the trees when the branches are damp soon destroys every vestige of Moss and Lichen which it touches. With these parasites the larvae of ordinary insects disappear also; but the greatest pest we have to contend with is American blight or woolly aphis, not that it is difficult to kill, as oils or spirits melt it in a moment; but when thoroughly established under the rough bark of old trees, the problem arises, how are we to get at it? Mr. Bunyard, a great authority, says the best remedy is Gishurst compound or soft soap, well rubbed in with an old brush. These I have used, also paraffin, which is more penetrating, but one dressing with either will not produce a clean sweep; therefore, the only course is patience and perseverance with an insecticide that will kill, and a determination to keep on as long as an insect appears on the surface. Few old orchards are free from American blight, but growers who are thus fortunate should be very careful how they

come an operation of the past, as the sap will be forced into the spurs by means of summer pinching. These remarks, as a matter of course, apply to trees on free stocks and not to cordons or small bushes on the Paradise, which can be kept within bounds for a number of years. But here even I question if longer life and heavier crops would not be secured by giving the trees more room and allowing them to extend laterally in every direction. Maiden trees on the English Paradise stock are cheap, but cheap as they are the cost of trees for an acre is a heavy item, and profit now being the order of the day, the plan I have previously recommended may advantageously be adopted. It is this: having prepared and planted, at the usual distance apart, the first acre, set about the trenching and preparation of the second. When in suitable condition, lift and transfer every alternate tree to its new and permanent quarters, allowing double the distance originally occupied. Pinch gross shoots to keep the trees properly balanced, and allow them to extend. All fruit trees should be lifted and replanted at the end of the second year, not perhaps to produce fertility, but to sever descending roots and train them in a horizontal position near the surface of the soil. The ground being ready, supernumeraries may, of course, be lifted at the end of the first year, but those left behind should stand two, or perhaps three, years before they are disturbed. The relaying of the roots at that age will set them in a course they will not depart from, and good annual mulching will draw the fibres to the surface. W. COLEMAN.

Esbnor Castle, Lodbury.

Forking amongst bush fruits.—"Cambrian" can hardly be aware of the fact that throughout the London market gardens forking is done liberally between and about bush fruits; even in some cases the spade is used, but only in a shallow way, as the men receive a moderate sum, perhaps 4d. per rod, for "turning in," and naturally it is not done deeply. I could show anyone now one of the finest plantations of Gooseberry and Currant trees in Middlesex several acres in extent which is forked over every winter after pruning is completed, and finer bushes than these or heavier crops are not obtained in any private garden in the kingdom. Manure is wheeled in during hard weather, spread about, under, and around the bushes, and then turned in somewhat roughly perhaps, but when a flat hoeing is given in the early summer the soil is fairly levelled. It must be remembered, too, that the soil about and beneath bush fruits, especially when grown under standard trees, as in the case just mentioned, gets hard trodden—very much more so, indeed, than is the case in private gardens. It does not follow that because one gardener adopts a certain rule in cultivation and finds it successful, that another rule may not be equally successful elsewhere. Certainly it is a fact here in Middlesex that forking or turning in amongst fruit bushes is the rule, and that it is a very satisfactory rule too. The bushes to which I have referred are some fifteen or sixteen years planted; they are very large, in robust health, and crop abundantly. No other method of culture could secure better results.—A. D.

Blenheim Orange Apple. I was glad to see Mr. Coleman's remarks (p. 533) on this fine Apple; it is an old favourite of mine, and undoubtedly one of the most valuable varieties which we possess. A grand specimen of this Apple in our old Worcestershire garden excited my admiration more than twenty years ago, and I have ever since recommended it wherever I could. Had I to plant an orchard or fruit garden, I should use more trees of the Blenheim Orange than of all other kinds put together. The fruit, which is large and handsome, also keeps remarkably well, and is equally valuable for dessert and culinary purposes. The growth of the tree is robust, the habit good,

and it is a remarkably fine cropper, the tree referred to often producing as much as twelve "pots" (a deep oblong basket, constituting a standard measure in Worcestershire) annually. When we came to London, we inquired for years in vain for Blenheim Oranges, and it is only during the last two or three years that we have been able to obtain them. Market and other large growers are, however, at last beginning to recognise the value of this grand variety. It speaks, I think, very ill indeed for the sagacity or intelligent enterprise of horticulturists that it has taken them, to my knowledge, about five-and-twenty years to recognise the value of such a treasure as the Blenheim Orange; though how long it is since this Apple was first sent out I do not know.—B. C. R.

VINES ON FLUED WALLS.

OVER twenty years ago I made the gardens at Cliffe Hall, on the banks of the Tees. We built all the garden walls hollow, and the south aspect wall was flued for Peaches, Apricots, &c. We planted three Black Hamburg Vines to occupy 10 yards of this wall, and had a border prepared for them, as for the other trees, viz., 3 feet deep and 18 feet or 20 feet wide. The border consisted for the most part of fresh turf. The garden was formed in the north-west corner of the park, and in making a cart road behind it we had to straighten a wood which here formed the boundary of the park. After cutting down the best of the timber we charred all the roots and branches, and as soon as the foundation of the wall was in we took a spade deep from the surface of the road and wheeled to the south side of the wall, covering with it a space of 40 feet, and mixing all with the charred mass, which amounted to several cart-loads. Previous to making the garden we drained it 4 feet deep. At a depth of 6 inches the soil was a strong holding loam. For many years we were able to hold our own with fruits against all comers, both in the collections and single dishes at exhibitions wherever we went. But to return to the Vines; we trained them horizontally the first year; then we led branches up the wall 3 feet apart, and spurred the upright stems 18 inches apart, no spur being opposite its neighbour. The third year we took fourteen or fifteen bunches from them, but afterwards we had from 100 to 120 bunches each year, each bunch weighing from 8 ozs. to 3 lbs. They were stopped as usual, leaving one or two leaves above the fruit the same as the Vines under glass; thinning the berries was also attended to with equal care, and when the Vines were fully established I cut off from 100 to 130 bunches before they bloomed, or just when coming into bloom, leaving a bunch to each spur. Thus treated, the fruit was equal to any we had in the vineries, both as to colour and flavour. It was often placed on the dinner table along with fruit from under glass, and visitors were asked to say which was hothouse grown and which not.

It was thought to be impossible to grow such good Grapes outside so far north. I exhibited them at Darlington, Bishop Auckland, Middlesborough, and other places, and growers held up their hands and said they were never grown outside; but as that fact had been disputed before, I invited the secretary of the Darlington Horticultural Society to come to Cliffe Hall the day before the show and see them cut. He then took them to Darlington, placed them on the table for me, and assured those who doubted that they were from outdoors that he had seen them cut and brought them to the show himself. In order to give some idea of the value of such fruit, I may state that I sold the Grapes as they hung on the wall to Mr. Pope, of Darlington, who gave me £1 per yard of wall for them, being £10 for the lot. At Sellarby Park, in Durham, close to Raby Castle, a vinery in the garden fell from old age. Vines were left on the back wall, which was flued, and they continued to yield good crops for many years after the vinery was down.

The following is a short outline of the treatment to which the Vines at Cliffe Hall were subjected:

In spring, about the latter part of April when they began to bud and grow, I had the wall-fire lit, and kept it going steadily all through the month of May; after that they had only sun-heat until the middle of August or 1st of September, when fire-heat was again employed and kept steadily on until the fruit was all cut, and sometimes longer if the wood was not ripe. The wall was 12 feet or 14 feet high, and had three tiers of flues. When the fruit began to colour, a 14-inch board was put under the coping, and the Vines were covered with fine Nottingham netting to keep off birds and wasps. The covering was ringed at one end, so that we could unhook it to cut the fruit. The net was so fine that we could see the fruit hanging on the wall from the walk outside a 20-feet wide border. It used often to hang several weeks after it was ripe; on the dry, warm wall it kept better than in vineries. Abundance of air passed through the net, and the leaves, when the wood was ripe, turned yellow and dropped down quite in a natural way.

I omitted to mention that in spring when the Vines began to grow, especially when the fire was lit, we poured two or three eans of water at the foot of the wall every day, so as to cause vapour to rise and thus prevent mildew. My neighbour's Vines at Sellarby used to suffer some seasons from mildew, which, I thought, arose from their being kept too dry. JOHN GRICE.

Moorlands, Sunderland.

The Prune Damson.—May I say a few words in favour of this old Worcestershire favourite? Not one Londoner in a hundred knows what it is. The only way we can obtain it is by getting it direct from Worcester or Pershore. The difference between this sweet and luscious fruit and the hard, sour material that passes for Damsons in London is almost incredible. I have heard it said that the Prune Damson does not bear so freely as could be wished, but I do not see how that can be the case, as I know that we used to have to prop up the branches of our "Prune" trees to enable them to support their weight of fruit.—B. C. R.

Pears—Beurré Diel.—"A Pear Grower" (p. 3) says: "Beurré Diel is not even a second class Pear." "A Pear Grower" must either be very deficient in the sense of taste, or else he has never had a fair example of Beurré Diel set before him. I either grow, or have grown, all the twenty or thirty leading sorts of Pears, and, taking them all round—I mean not deciding by any one one point alone, but weighing all points, growth, fertility, flavour, size, ease of ripening, appearance, &c.—I find Beurré Diel well to the front of them all. Comice I fancy as *facile princeps*, afterwards Bon Chrétien, Pitmaston Duchess, Winter Nelis, and Hardy, and then I should put Beurré Diel. Easter Beurré, Chaumontel, and Glou Moreau are grand when they properly ripen. Knight's and Gansel's are glorious when they bear. Many others are superb when they come big enough to be of real use. I am, however, far from despising small things in flowers, fruits, or vegetables; indeed, I think a great deal too much is thought nowadays of mere size, but still it is undesirable that so many exquisitely flavoured Pears should come, as a rule, too small for the dinner table. Josephine de Malines I am at present greatly disappointed with. I have never yet grown it worth eating for flavour, and Superfin has at present baffled my efforts, but I hope to succeed with both before long. Marie Benoist bids fair to be excellent if it gains fertility with age. But my dear old friend Beurré Diel every year gives me a crop on a half-standard. The fruits are always of good size, always excellent in flavour, and the only possible fault to be found is that in some seasons some of them are just a little bit granular. The mass of the flesh is, however, so soft and melting and so superbly scented, that the grains pass unnoticed, or at least are freely forgiven for the rest's sake. The old Louise Bonne is with me a great favourite. I can quite understand, however, that many would dislike its very peculiar flavour, but everyone must like a good Beurré Diel. The reason "A Pear

Grower" never gets it good is, I fancy, either his soil or his stock; mine is on the Pear stock and in very light sand. I think anyone writing on Pears should be very careful to state what soil and what stock they are on, and also if on a wall what aspect.—W. WILKS, *Shirley Vicarage, Croydon.*

ROSE GARDEN.

NOTES ON ROSES.

EVERLASTING ROSES.—On p. 583 "T. S." refers to twenty-six kinds of China Roses, and says, "are there not many more varieties than ordinary folk dream of?" There certainly have been, even if they no longer exist, or linger only in old-fashioned gardens, nameless and forgotten. A little time ago it occurred to me to try and gather together a complete collection of these charming, ever-blooming Roses, and I began to look up their names and local habitations. In the course of an afternoon I had compiled from modern catalogues and books in my possession a list of no fewer than 370 names of varieties of the China Rose, all fully described, and many with the raiser's name and some with the date of their introduction. This list excluded all hybrids (such as the so-called hybrid Chinas) and all varieties which appeared to approach the accepted character of the Tea scented and Noisette classes. These China Roses, according to their descriptions, included almost every shade of colour from white to black, for there was the Black Bengal Rose described as dark crimson, shaded with purple and black; while the terms blush, lilac, rose, pink, red, crimson, purple, striped, mottled, carmine, and dark velvety frequently occurred. It is not much wonder, therefore, that in old gardens where things have escaped the destruction decreed by the vagaries of fashion that many varieties distinct from the typical China Rose should be discoverable, although their names and history be lost or forgotten; for in all probability the 370 names above referred to do not represent nearly all the varieties that have been raised and distributed. The earliest dates of distribution that I have noticed are those of some of M. Joly's seedlings in 1835 and 1836. Now the China Rose was known in Europe in 1789, and there was plenty of time in the intervening forty-five years for the raising and distribution of any number of seedlings whose names and origin may have been outlived in some old-world garden in France or Great Britain by the plants themselves. The raiser, whose name occurs most frequently in connection with these Roses, was M. Laffay, distinguished as the raiser of the once celebrated *La Reine*, and who distributed seedlings, at any rate, from 1839 to 1863 (probably for a longer period), and next comes M. Vibert, whose dates range from 1828 to 1852 at least. We may therefore fairly conclude that numerous varieties raised and distributed at the beginning of the century, although their names and descriptions be not recorded, may yet themselves have survived to render even more impossible the well-nigh hopeless task of identifying growing plants by means of existing descriptions. Perhaps the best chance of finding out about these Roses would be in some of the older nurseries in France, where the names may possibly still linger round some veteran plants, which in that case would afford some basis of comparison. But, at any rate, it would be highly interesting to compare and learn as far as possible about existing varieties that have proved, by their survival, their hardiness and value as permanent garden plants, whether their original names can be fitted to them or not, for, after all, the plant's the thing, and even a China Rose will not be likely

to lose in attractiveness by the substitution for its own of any other name.

NEW TEA ROSES.—I am glad to have the good impression made by my few plants of some of the Tea-scented varieties of the year confirmed by the record of their trial on the larger scale described by Mr. E. G. Hill. Judging from the plants I have as yet flowered, I should quite concur in placing *Comtesse de Frignense* (Guillot) at the head of the list of the French novelties, and the attractive clear yellow colour of its deep-pointed flowers is certain to make it popular. My only doubt about it is whether it is quite full enough; but it is said to be so, and it comes from a raiser who has sent us some of our best Teas. *Claudius Levet* (C. Levet) is a promising variety with large, full flowers, too substantial for use in the bud state for bouquet work, but likely to be an addition to the list of exhibition Teas. *Marquise de Vivens* (Dubrenil) has been very highly spoken of in France, where two medals have been awarded it as a good novelty, but my flowers struck me as more in the way of *Madame de Watteville* than of *Madame Cusin*, the petals shading from a yellowish white base to a rosy margin. These shaded Teas, however, vary so much in tint even on the same plant, that it is very difficult to speak with certainty of their prevailing colour until after several seasons' experience of any given variety. Take, for instance, *Madame Lambard* (of which *Souvenir de Victor Hugo* Bonnaire) put me somewhat in mind both in its varying shades and in its freedom of flowering, a variety from a few plants of which one may often gather half-a-dozen blooms so different in colour that to describe each at all exactly would involve half-a-dozen separate descriptions. Two other French varieties, which Mr. Hill does not mention, struck me as likely to be desirable, namely, *Comtesse Horace de Choiseul* (Lévêque), a rose-coloured Tea of great substance with a pointed centre, the flowers being produced on stiff, erect stems, and therefore showing themselves to advantage on the plant; and *Marguerite Ramet* (C. Levet), a pretty light Tea with rosy margin and a similar upright, and therefore decorative habit of growth. I was surprised that in a selection of the new Teas of 1886, *The Bride* (May) was not included, but, perhaps, as it originated in America, it is reckoned in that country as an 1885 Rose. It reached us, however, at the same time as the above mentioned French novelties, and bids fair, in colloquial phrase, to take the cake. It originated in the garden of Mr. J. May, of Summit, New Jersey, as a sport from *Catherine Mermet*, and, unlike most Rose sports, it appears to produce flowers as fine in form and substance as its parent. The only difference so far discernible between plants of the two varieties lies in the colour of the flowers, which, in the case of *The Bride*, instead of being flesh-pink, like the type, are white with just a tint of lemon colour at the base of the petals. Assuming that there will be some Roses left after the Arctic winter that we are now experiencing 25° of frost 4 feet from the ground, Jan. 1 and 2), *The Bride* may confidently be expected to make a good appearance at some of the Rose shows of 1887.

NEW ROSE COMTE DE PARIS.—It is a pity that Rose raisers cannot come to some uniform arrangement by which the inconvenience arising from the giving of the same name to different varieties might be avoided. The seedling now being distributed by Lévêque under the above name is the fifth *Comte de Paris* that has been sent out, two Hybrid Perpetuals having been put into commerce respectively by Laffay and E. Verdier, and two Teas by Hardy and Madame Pean; while the chances of confusion are in no way

lessened by the existence also of two Hybrid Perpetuals under the name of *Comtesse de Paris* (E. Verdier, 1864, and Lévêque, 1883). In the same way there are already three varieties involving the name of Victor Hugo, and the Rothschild Roses have lately been increased to five in number (all Hybrid Perpetuals) by the addition of two varieties with the barely distinguishable appellations of *Baron* and *Baronne Nathaniel de Rothschild*. This *Comte de Paris V.*, so eulogised in the *Tuscany Horticultural Society's Journal*, is rather more moderately referred to in the general list of Continental novelties as follows: Flowers red, shaded crimson-purple; of good size and form; robust only.

ROSES FOR A SMALL GARDEN.—In his selection under this heading, would not "J. K." consent to the substitution of *Reine Marie Henriette* for *Cheshunt Hybrid*, of *William Allen Richardson* for *Belle Lyonnaise*, and of *Marie Van Houtte* for *Devoniensis*? I have found *Reine Marie Henriette* quite as vigorous and free-flowering, and not so liable to mildew, as *Cheshunt Hybrid*; while the flowers of the former are really pure in colour. I may be thought fastidious in the matter of dingy colour in flowers, but I believe quiet, soft colours may be obtained without muddy tints, and I should as soon think of trying to cheer up a sick schoolboy with extracts from a Latin grammar as of recommending anyone who had only space for a dozen Rose trees to include *Cheshunt Hybrid* in the number. *Belle Lyonnaise*, again, is woefully tender, and, with identical protection, was last winter more injured than almost any other Tea, consequently not flowering until September; whereas *William Allen Richardson* is essentially a Rose to run to (which is what is wanted in a small garden), having the good qualities of colour, abundance, vigour, hardiness, foliage almost evergreen, and flowering early and late. *Devoniensis*, as "J. K." says, is not very free, but this objection cannot be urged against *Marie Van Houtte*, which is as free and (may it be said?) more beautiful than old *Gloire d'Orléans*. Perhaps "J. K." writes from a happy land where *Cheshunt Hybrid* has no lilac shade, where no frosts interfere with the long growths of *Belle Lyonnaise*, and where *Devoniensis* is not shy; but in a climate so conducive to luxuriant growth it might be desirable to grow *Jules Margottin* as a dwarf plant, and consign *Cheshunt Hybrid* (or its substitute) to the walls, lest in a bed with three *Gloire de Dijon* such moderate growers as *Captain Christy* and *Victor Verdier* should be altogether overwhelmed. T. W. G.

THE GREAT SNOWSTORM.

THE snowstorm of the 26th played sad havoc in our pleasure-grounds; in fact, so far as ornamental trees are concerned, I think the consequences are even more disastrous than those that followed the memorable snowstorm of January 18, 1881, or the great gale of October, 1880. Amongst evergreen trees the Cedar of Lebanon has, as usual, suffered most, and the fact should always be borne in mind when it is about to be selected for planting that its value as an ornamental tree is considerably lessened by its extreme susceptibility to injuries of this kind; indeed, in many cases it hardly attains its full beauty before heavy storms tear away its branches and cause unsightly gaps. The *Deodar* and *Atlantic Cedars* are comparatively uninjured. Many of the different varieties of *Cypress* and *Juniper* have suffered severely, and so also have the heavy *Pines*, such as *Cembra*, *Strobus* and *Lambertiana*. *Cembra* especially seems almost as susceptible to injury from storms as the *Lebanon Cedar*. I am glad to say that very few of the *Abies* have suffered; stiff-foliaged varieties, such as *cephalonica* and *brachyphylla*, and feathery-leaved kinds, such as *Menziesii* and *Molina*,

have all escaped. Evergreen Oaks and Hollies are badly broken and in many cases perfect wrecks. Amongst deciduous trees, Beeches have been most severely injured, and after them Oaks with horizontal growths. I attribute the slaughter amongst the Beeches to the fact that with us they are short lived and have a lot of half-rotten wood in them. Rare deciduous trees have fortunately escaped. The fact of so much wood lying about reminds me of the request made the other day in THE GARDEN as to the burning qualities of different kinds of wood. The majority of our houses here are flue-heated and worked principally with wood. Of the commoner kinds that we have tried, Oak, Apple, Elm, and Beech are about the best amongst deciduous trees, and Cedar is perhaps the best amongst Evergreens; all kinds of Fir are of very little use; they have no lasting qualities, and consequently they want far too much attention. The very worst of all firewood is Chestnut; this is practically useless, unless sparingly used with other woods, fire seems to have no power over it—at least in a green or half green state. The commoner shrubs when they have attained considerable size make useful fuel; big old Rhododendrons are also useful for lighter firewood, from the rapidity with which they dry after being cut.—E. B.

— The great snowstorm of December 26 and 27 and afterwards has revealed such numbers of wrecks in gardens, pleasure grounds, fields, and forests as have seldom or never resulted from a single snowstorm before; for it was the snow, not the wind, that produced the arboreal wreck and ruin everywhere seen or heard of. The wind, which blew half a gale on the early morning of the 27th ult., saved probably thousands of trees and shrubs from utter and complete destruction: it did double service by shaking off the crushing weight of dripping snow where that was possible, and also by preventing the still fast-falling snow from accumulating to greater thickness on the branches. Hence it may be safely assumed that, but for the wind, the wreck and ruin, heavy as it is, would have been far more disastrous. As it is, it is bad enough, and has made terrible havoc among the finest Cedars of Lebanon and many other monarchs of the garden, park, and wood throughout the country. Probably Cedars of Lebanon have suffered most; their far-reaching, dense boughs seem made on purpose to collect and carry as much snow as possible. The size and rigidity of the limbs of old Cedars also force them to hold fast all soft snow that falls upon them. And thus it happened that as the wet snow poured down with a volume and rapidity probably unprecedented, the boughs bent lower and lower until the burden became insupportable, and down they came. The position of the boughs, their line of divergence from the trunk, and their stubborn strength and unyielding rigidity all but augmented the ratio of destruction in the case of the Cedars of Lebanon. The trees and shrubs, in fact, that refused to bend had perforce to break. Next to the exceptional wreckage of Cedars, the most notable results of the snow were the number of branches torn off deciduous trees, such as Walnuts, Spanish Chestnuts, Oaks, Ashes, Elms, and even deciduous shrubs. Since the snowstorm we have also had a double dose of 20° of frost two nights in succession, and a large proportion of the snow is still with us, though it has also thawed for a few hours several times. As I write on the 3rd, the weather does not seem to have decided whether to rain or snow. It is to be hoped that we may not have a second addition of such a destructive snowstorm. A thaw would be most welcome to allow of the removal of broken limbs, the dressing of wounds, &c., as few things are more against the quick healing of wounds in trees than the exposure of their raw edges in a splintered state to 20° of frost. Can any reader of THE GARDEN recommend a safer waterproof and healing emollient for wounds than a mixture of grease and tar?—D. T. F., *Bury St. Edmunds*.

— Our woodland here (N. Hants) is simply ruined. A foot and more of wet snow came after heavy rain on the 26th and froze to the trees. At

midnight a wind rose which snapped the limbs and stems of the ice-laden trees like so many Carrots. Of deciduous trees, Oaks have fared the worst. But the saddest sight is to see the entire tops of fine specimen Conifers lying on the snow. A clean sweep has been made of Scotch Firs. The beauty of Chute Lodge Park, a very tastefully planted estate just over the border in Wiltshire, is destroyed for a generation or more to come; scarcely a Conifer has escaped. Biddesden Park, another finely timbered place, is similarly dismantled of its trees, its owner's great pride. The havoc all round here must be seen to be believed.—G. H. ENGLEHEART, *Appleshaw, Andover*.

— At this place we have lost dozens of fine trees. *Thuja borealis*, *Cryptomeria japonica*, Cedars, Yews, and Junipers are the evergreen kinds that are most injured. Tall Rhododendrons are broken right down, but this is a small matter, as they will quickly recover. Amongst deciduous trees, those most injured are Elms, Horse Chestnuts, Oaks, and Beech. Immense boughs are broken down in all directions, many of the finest trees being so disfigured that they will have to be cut down. Fruit trees have not escaped. Standard Plums and Pears, on which the boughs were long, are broken down close to the main stem, and Gooseberry and Currant bushes are literally flattened to the ground. The only word that can describe the damage is "terrible." Not only has there never been such a snowstorm known in these parts in my lifetime, but a gentleman, who is over ninety years of age and who has always resided in this country, assures me that never before did he remember so much snow fall in so short a time. May it never be experienced again, though whilst I write (January 4) signs are not wanting that a second edition is in store for us.—W. WILDSMITH, *Heckfield, Hants*.

— The storm of December 26 will never be forgotten by lovers of trees and shrubs. Fine old trees of Oak, Beech, Elm, Scotch Fir, and Chestnuts have been blown down and otherwise damaged; while in the gardens here very fine Cedars have lost large branches. Various other Conifers have also had their branches torn off from top to bottom. Catalpas, Evergreen Oaks, Cork trees, Judas trees, Acacias, and many others, including Magnolias, Laburnums, Tulip trees, and Aspens, have likewise all sustained damage. Rhododendrons, Hollies, Portugal and common Laurels are uprooted and broken, in some instances to pieces. In fact, from nine o'clock in the evening till early morning there was a continued crashing and smashing of timber. Trees that have stood for over a century are down, and, in the case of many rare and choice trees, fifty years' growth will not replace the damage. Although the snow was of such a wet and heavy character, yet in eight hours it had fallen to a depth of 15 inches, and, with a strong north-east gale blowing, it in places was much drifted.—W. C. LEACH, *Albury Park, Surrey*.

Wet and dry bulb thermometers.—I was much pleased and instructed by the short article and table in a late issue of THE GARDEN on the wet and dry bulb thermometer as a guide and indicator of what amount of frost might be looked for on any night. I wish "F. W. B." would go further, as I am sure the use of the wet and dry thermometer for gardeners and amateurs does not end there. As a cultivator with but little experience, and, perhaps, less of science, I am often puzzled by instructions in gardening papers, such as a nice growing temperature, a moist, healthy temperature, &c. Now I think if this combined instrument were more used in our greenhouses and quoted by writers on growing different plants we would be better able to understand what was meant. The dry bulb gives us, say, the temperature of any greenhouse, intermediate or stove house, and the wet bulb by a formula will give us the amount of moisture in the house at this given time. I am sure "F. W. B." can supply us with a table showing from the reading of this instrument what amount of moisture there is in the air of any house at any time by reference to the wet and dry bulbs. This would be very useful. I do hope to hear more of this subject; I am gazing after knowledge in this direction myself, having a maximum and also a wet and dry bulb thermometer I use in a small house at present, but I lack the knowledge as to what amount of moisture should be allowed in the air for various plants in varying temperatures.—ENGINEER.

GARDEN FLORA.

PLATE 578.

THE CALIFORNIAN FUCHSIA.

(Zauschneria californica, with plate.*)

THE first notice which we have of this truly handsome plant, the only representative of the genus, is in the "Annals of Botany" (vol. i., p. 543), where it is alluded to as follows:—

This beautiful new genus, a native of California, has the flowers of a Fuchsia and a fruit exactly like that of an *Epilobium*. The genus was first named and described by Presl, in his "Reliquie Haenkeana" (p. 52), and was first introduced by the Royal Horticultural Society in May, 1847, through Hartweg, who collected the seeds in fields about Santa Cruz; and we have also a record of its having been cultivated at Kew in 1852.

Among the many striking hardy plants in cultivation at the present time, this so-called Fuchsia takes a high place. It has the graceful drooping habit which is so much admired in the Fuchsia, together with the advantage of being hardy in most parts of the country. When left to itself, it is inclined to become leggy, but a little management bestowed upon it in the early part of the season soon remedies that, and as flowering time approaches it will be found to have become compact in habit, and to be furnished with a correspondingly large number of its handsome vermilion-coloured flowers. The best plan, we find, when a group of it is contemplated is to plant pretty closely together, and pinch back the young growths as they make their appearance. A compact bed is thus formed, with innumerable shoots, each bearing flowers in such abundance, as to present collectively a mass of vivid colour. Hardy-plant growers seem to fight shy of this plant, but it will be found on trial to withstand even our severest winters in most places. In particularly heavy soils or in low-lying districts, a slight covering in winter may be given it, but that is all that is needful. It lasts long in flower, and as it does not begin to bloom until towards the end of summer, as sunny a spot as possible should be chosen for it, as in shady positions autumn frosts not unfrequently destroy the flowers. This induced us to try it as a pot plant in the greenhouse, where its bright flowers are very attractive, especially during the late autumn months, when most plants were long past their best. When protected in this way from frosts, it continues to flower long after plants of it have been blackened in the open air. It seems to vary much in habit, and also in the degree of hairiness, size, and shape of the leaves, both in a wild state and under cultivation. This variability has given rise to the variety *latifolia*, figured in the *Botanical Magazine* (tab. 4493). In some the leaves are slightly hairy, in others they are villose, and even tomentose, and under cultivation perfectly glabrous and shining. We lately saw a curious dwarf form which differs widely from the type, but it has smaller and less showy flowers.

This *Zauschneria* is easily propagated. It strikes freely from cuttings taken off early in autumn and wintered in a cool frame, from which they may be planted out where required as early as April. It may also be increased by division of the old plants or by seeds. The latter, if sown early in a little heat and grown on, will flower the same year, although not so freely as older plants. Young seedling plants are, however, easier to establish on old walls or perpendicular rockwork, where they assume a hanging or drooping habit, and add considerably to the general

* Drawn for THE GARDEN in Dr. Lowe's garden, Woolcote, Wimbledon.

Eauschnefia californica

effect. When once they get a firm hold they are not long in filling the space allotted to them, producing flowers in the greatest profusion. It grows, as a rule, from about 9 inches to 2 feet in height. It is generally much branched and erect, with drooping points or altogether decumbent leaves, the lower ones opposite those above alternate on the stem. The flowers, as may be seen, are large vivid scarlet or vermilion, and resemble those of a Fuchsia with exerted style and stamens. The roots in light dry soils have a tendency to creep much in the way of those of the French Willow herb. The variety *latifolia* has very broad leaves, and seems to run into the variety called *mexicana*, which is intermediate between the two; it is even possible, where large quantities are grown, to have a complete gradation from the one to the other. *Z. californica*

Zauschneria californica, showing habit of growth.

nicia var. *microphylla*, a plant named by Gray, is not in cultivation. It has very small, narrow, tomentose leaves, clustered at intervals on the stems. The flowers are also smaller and less vivid in colour than those of *Z. californica*. It is found in dry localities from Napa and Plumas counties to S. California. The type is common both in southern and lower California.

FRUITS UNDER GLASS.

LATE VINERIES.

If late Grapes are still hanging on the Vines and bottling is intended, no time should be lost in getting them cut and transferred to water. The management of Grape stores being now so well understood by all readers of the horticultural journals, a repetition of details is quite unnecessary, and those who have not made themselves thoroughly master of the subject have only to refer back to past volumes of THE GARDEN. One thing, however, I must repeat, and that is the caution against the use of fire heat, so long as damp does not get into the bunches and the room can be kept at a temperature of 40°. When all the Grapes have been cut the house should be thrown open to atmospheric influences, and the internal borders, having been cleared of all loose covering, may be gradually brought back to a growing condition by repeated applications of water from the cisterns. External coverings, in the form of glass lights, corrugated sheets, or shutters, must also be removed, and, provided the borders are well clothed with Fern or litter, they may be left open to the influence of the elements. The next operation is pruning, cleansing, and tying-in ready for a fresh start, but with the well-known fact that late hanging is tantamount to early forcing before us, a long rest must be secured by keeping the house dry and as cool as possible until the buds show signs of swelling. Many growers are obliged to turn their late vineries into plant houses as soon as the Grapes are cut, but unless the occupants are very hardy and capable of withstanding a degree or two of dry frost, the practice, if possible, should be

avoided. January pruning is not often followed by bleeding, but, bearing in mind that root-watering closely precedes or follows pruning, the application of styptic should not be neglected. A shilling bottle of Thompson's styptic will dress all the wounds in several houses, or, lacking this, painter's knotting will answer equally well. The old-fashioned method of scraping Vines having been given up by all good Grape growers, a rub with the hand to disturb the rough bark is all that is needed, even where bug is present. Washing with strong soap water follows, and, finally, by way of precaution, a solution of Gishurst compound, 8 ozs. to the gallon of water, or 4 ozs. of soft soap and half a pound of sulphur, thoroughly mixed with the same quantity of water, may be well worked into the old spurs with a half-worn paint-brush. If bug is present, gas tar may take the place of Gishurst compound; but it is a powerful insecticide, and must be used with caution always when the Vines are at rest. Although I have often given instructions privately and in print for its preparation and application, a repetition may meet the eye of some despairing person who has often tried remedies and failed. To 1 gallon of dry, finely sifted loam, placed in an iron pot over a slow fire, add half a pint of tar; mix the two thoroughly, then pour in as much boiling water as will reduce the mass to the consistency of thick cream. Having washed the Vines, cleansed and painted the house and dressed the walls with quicklime and sulphur or paraffin, clear away all loose soil and mulching, commence at the base of each rod, and thoroughly encase it with the paint. It is not the quantity so much as the even distribution of the paint and the filling of all old gnarles and holes that kills the insects. Some use it much stronger, but I can vouch for these quantities answering the purpose; but it must be borne in mind that solitary insects may escape the fumes, or they may be biding their time in the borders. These for a time will do no harm, but with returning spring they will put forth, and must be taken one by one as they appear. Although etching and killing is allowed to be the only remedy, the most expeditious mode of annihilating the stragglers will be found in the use of methylated spirits applied with a camel's-hair brush. Armed with this in a wide-mouthed bottle, which can be kept tightly corked when not in use, the attendant should examine every spur for some weeks after the Vines break, when a touch with the brush will melt the enemies in sight in a moment, and a second dip applied to the hole or crevice from which they have emerged will prevent others left behind from following. Many people having painted their Vines with tar rest satisfied, but really the work of extermination only commences where they cease from troubling about the most persistent insect—Phylloxera excepted—that ever entered our vineries.

Pot Vines.—Where these are grown from the eye and fruited upon the premises, a number of operations will now require attention. One of the best trade growers of pot Vines with whom I am acquainted always puts in all his eyes before Christmas, and the fruiting yearlings he turns out are models of perfection. Others put them in as late as February, cut back, and grow them on the second year for fruiting. Vines of this stamp should now be cut down to a good bud close to the soil, and having been touched with styptic, be allowed to stand where they will be safe from frost and wet until the end of the month, when they may be started. A bed of fermenting leaves placed in an early vinery or pit into which the pots can be lightly plunged forms the best of starting mediums, for much as the Vine enjoys copious supplies of water when in full growth, a sudden condition of the soil is often fatal to the best roots when it is slowly recovering from decapitation. The warmth and moisture arising from the leaves supplemented by daily syringing will be found quite sufficient to start the buds, and when 2 inches in length they should be shaken out and repotted. Vines intended for planting out later on may be shortened back to any convenient height to get the base buds forward, but unless they are likely to be wanted before March,

they should be kept semi-dry and as cool as possible.

Fruiting Vines.—With a steady bottom-heat of 70° playing about the crotch roots these will now push on apace, and pay for the patience exercised through the early stages of their growth. Well ripened canes generally break double, and require disbudding as soon as the strongest of the two shoots takes the lead; being close-jointed, the breaks from every alternate eye also require removal, but instead of rubbing off close home these shoots may be closely pinched to two or three leaves, which will assist the roots and aid in the development of the canes. When the bunches show, all but the strongest and best must be removed from every shoot, and the latter stopped at the second or third leaf in advance. All laterals and tendrils, too, must be pinched, and when strong enough the fruit-bearing shoots must be gently drawn to the wires. This stage reached, Hamburgs, Fosters, and Bucklands may range about 60° through the night, 65° when the weather is mild, and 70° by day. The syringe may be freely used about the walls and other surfaces every morning, and overhead about 1 p.m., when the temperature has reached the maximum, up to the time of flowering, when a higher and more buoyant atmosphere will facilitate the setting of the fruit. Being free setters, the Vines need not be taxed with a superfluous number of bunches, eight being quite sufficient to choose from; these it may be well to fertilise with a camel's-hair brush every day, and when set they may be reduced to five or six, according to the strength and vigour of the Vines. If the pots are standing on pedestals, frequent renovation of the bed will stimulate the roots and greatly assist the fruit and foliage, as direct syringing will have been discontinued. The roots, too, will derive benefit from liberal supplies of warm diluted liquid whenever water is needed, and good top-dressings to be washed in and replaced from time to time must not be overlooked. As days begin to lengthen and the sun gains power, a little more air should be admitted every morning and shut off about mid-day to encourage growth, and, if practicable, a chink at the apex through the night, if only to let out vitiated air, will keep the Vines robust and healthy until the most trying part of the season has been got over.

Early vineries.—The air temperature in these should range from 50° to 56° through the night, and 60° to 65° by day, until all the buds are fairly on the move, and when this stage is reached an extra 5 will be necessary. Much, however, depends upon the weather and the treatment to which the Vines have been subjected in previous years. At the present moment the glass registers 17° of frost, and no one would think of maintaining a hard and fast line, especially when clear frosty nights are followed by bright sunny days, and an extra 10° can be secured by closing early. The practice, then, in favourable forcing weather should be the loss of 5° by night, and the compensating gain of 10° through the day. Old Vines which invariably show an abundance of bunches may be disbudded when the breaks are an inch in length. Young ones, on the other hand, should be allowed to declare themselves before the shoots are reduced to the requisite number. Tying down at this early season requires great care; little at a time and often is the proper method. In fact, provided the shoots are kept clear of the glass, and lightly looped ties draw them in the way they are to go, the most obstinate shoots will soon settle down to the wires. Stopping must be regulated by the space at command; in all cases, with the exception of leaders, the shoots should be stopped at the second or third leaf beyond the bunch; then, provided the openings admit, semi-extension may be practised on the first set of point laterals. Some growers pinch and repinch at the first leaf, but crowding being avoided, the young growths should be allowed to extend until every part of the trellis is covered with leaves. If the inside borders have not been watered since the Vines were

started, a good supply at the mean temperature of the house may now be necessary, and renovation of the fermenting material will certainly be a great help in keeping the atmosphere moist, and counteracting the drying influence of fire-heat. External borders, hitherto covered with Fern or litter, with or without shutters for throwing off snow, may now be treated to a good layer of dry warm leaves as a stimulant to the surface roots. Many object to external heat, and so do I if it is produced by rank manure, but dry Oak leaves are mild and constant, and assist the roots without poisoning the compost.

The succession, also the early Muscat houses may now be closed, or, where closed before Christmas, they will be in a fit state for gentle fire-heat through the day. Water at a temperature of 90° and a supply of fermenting leaves having been introduced, the Vines will soon break, when detailed management recommended for the early house may be repeated. As days increase in length and forcing is no longer quite dead against Nature, the heats may often be increased, but always on the give-and-take principle, the first applying to cold nights, the second to bright gleamy days. If Hamburgs, the best of all male parents, are not likely to be in flower when early Muscats and kindred varieties require fertilising, a good quantity of pollen should be saved from the earliest house for this purpose. Forewarned, forearmed, as it is well known that these shy sorts require assistance, but it is not generally known that pollen shaken into a box and kept quite dry will retain its power for some time after it is gathered.

PINES.

The earliest set of Queens expected to throw up their fruit next month will now be on the move, and must be very carefully supplied with water. If well plunged in moist leaves and the house is kept in a growing state, their requirements will neither be heavy nor frequent, but when to the experienced eye water is needed, enough to reach the crock roots must be given. Warm, diluted liquid may be used for this purpose, also for filling the evaporating pans and moistening the surface of the bed. The roots having been rested in a bottom-heat of 70°, all should be alive and ready to respond to the call that will speedily be made upon them, but, in order to assist the fruit to the utmost, a few handfuls of rich, turf compost or turf, pure and simple, may be packed tightly about the collars of the plants. It may be advantageous to remove a leaf or two to set the stem roots at liberty, always provided this can be done without disturbing the plants; then, as the work is proceeded with, the formation of a very compact cone round each stem will check the downward passage of water from the axils of the leaves and throw it outwards towards the rims of the pots. A watchful eye, it is hardly necessary to say, must still be kept on the bottom heat thermometer or watch-sticks, and if it is found that any part of the bed has heated dry or is getting too cold, a moderate supply of hot water poured in between the pots will most likely revive the fermentation and render renovation unnecessary. Many Pine growers start their earliest plants in a very strong bottom-heat, ranging from 90° to 100°, but once the fruit is on the move, 85° to 90° is quite high enough to insure rapid growth equal to the amount of light at command and favourable to the formation of perfect crowns. Aided by an abundance of hot-water pipes—the best safeguard against over-heating—and the assistance of warmth from the bed, there should be no danger of reducing the temperature of the house to any appreciable degree by the daily opening of the ventilators, if only for an hour or two to change the atmosphere. A chink at night also near the front pipes will tend to the vigour of the plants and prevent the crowns from becoming drawn. Next to efficient fire-heat, a covering of some kind, if only along the front or windward side, will be found a great help in cold weather, especially when nights are bright and the escape of moisture is very rapid.

Successional fruiters.—If these, by the pointed look of their centre leaves and the thickening of the stems, show signs of following closely on the heels of their predecessors, one of two courses may be adopted. A portion of the most promising may be drawn and started at once, or the whole house may be brought on steadily by a gradual increase of top and bottom heat and atmospheric moisture. As few people now grow Pines for market, small pits or houses divided into compartments answer best for giving a continuous supply of fruit throughout the year, as not only can the plants be brought on in batches, but, having a dry compartment, ripe and ripening fruit can be kept for a considerable time in a sound condition.

The general stock, including Rothschilds, Cayennes, and perhaps a few Queens, which has been kept moister and cooler than early starters, should not be hurried, as the finest fruit is always obtained from plants which grow on until daylight more than counterbalances darkness. Young stock must be kept quiet for the present, but the time is at hand for re-potting and a general turn over, and as weeks soon steal away, crocks, pots, and compost should be prepared for use when wanted. If plenty of good loam has been wintered under cover, this will only require breaking up and correcting, but turf from the open-air stack should be broken up by hand and placed in a warm, airy house or potting shed some weeks before it is wanted. Eastnor Castle, Ledbury.

KITCHEN GARDEN.

FORCING ASPARAGUS IN BEDS.

THE practice of forcing Asparagus in permanent beds has never been adopted so much as the merits of the system deserve. It is certainly a more economical plan than that of lifting the roots and forcing them in other structures, as such roots, after being forced, are of no further use, while a well-managed set of permanent beds may be made to last for several years. Handy portable, span-roofed frames are now manufactured that suit Asparagus-forcing perfectly, and the produce from permanent beds is always larger and better than that from plants lifted and forced in the ordinary way. I have had Asparagus produced by this system as large in the beginning of March as I ever cut from beds in the open. We used to commence cutting about the middle of December, and continued to do so until Asparagus came in in the open air. Unless, however, anyone has plenty of frames as well as space, I do not recommend such early forcing, because unless the frames can remain on the beds until late in spring the plants suffer so much from alternate rain and frost, that it takes them a year longer to recover themselves. In the majority of cases it is best to commence forcing early in January, and then the first cutting may, according to the weather, be expected to take place in five or six weeks. I am assuming that the heat supplied will be obtained wholly from fermenting materials. I have had no experience with hot-water pipes in connection with this work. Doubtless, a single 1-inch hot-water pipe run along the centre of the bed 18 inches below the surface would be of great advantage in assisting to start growth, but this is not absolutely necessary. I may say, indeed, that I am so well satisfied with the results which I have obtained from the use of fermenting materials in ordinary trenches, in conjunction with portable span roofed frames, that I do not see the necessity for a greater outlay.

In order to obtain a satisfactory supply of heads, it is necessary that the beds be pretty closely packed with plants, and that they be thoroughly well established in the soil before they are forced. If I could choose the size of the frames, I would not have them wider than 3 feet 6 inches, i. e., the size of the bed. The wider the beds the greater the difficulty there is in warming the soil, and unless

this can be done the heads come up round the sides first and in the middle last. Beds the size I have mentioned will get warmed through if the trenches are well filled with good fermenting materials. The sides of the frame should be 1 foot high, and up to the angle of the span they may be from 2 feet to 2 feet 6 inches. If new beds are to be laid out for this purpose, I should recommend them to be formed as near as may be convenient to the frame ground, or some other position in which a wagon or cart could be made use of for bringing in the heating materials, not a small quantity of which is required when forcing commences early. As already indicated, the width of the beds must be guided by that of the frame. The bed should not be more than 4 inches wider than the frame, and the width and depth of the trenches between the beds should be regulated by the width of the beds. A bed 4 feet wide requires a trench on each side 3 feet wide and 2½ feet deep. Narrower beds may have proportionately smaller trenches, but in every case sufficient space must be provided to hold a good quantity of fermenting materials. In forming the beds, I need hardly say that the soil must be made sufficiently rich to promote a vigorous growth. Early in April is the best time to plant, just as the young heads are rising through the ground, and three-year old plants are best, as they soon get established. They should be planted 1 foot apart each way; and in order to give them time to get strong, they ought to be allowed to make two years' growth before they are forced. While getting established, no heads should be cut from them. A sufficient number of beds should be provided, to allow one lot to be resting while the other is being forced. To enable anyone to judge how many beds are required to keep up a constant supply, I may mention that each bed remains in a bearing state for about three weeks. If cut from longer than that, the plants will be weakened. About 60 feet run of beds will be required to furnish a supply for a moderate sized family.

The preparation of the fermenting material should be the same as if it was required for making an ordinary hotbed; the more preparation it receives the more regular and lasting will be the heat. I prefer about half stable manure and half leaves. In filling the trenches the material may be lightly trodden down, and it must be made as high as the top of the sides of the frame; unless there is a good body of material the heat will not be sufficient to start the plants into growth. It may also want adding to, as it sinks down. I cover up the frames with mats as soon as put on the beds, and keep them in darkness until heads begin to come through the soil; at other times the frames are covered at night. The frames do not require any air until growth makes its appearance; then they require a fairly good supply and all the light possible, so as to get the Asparagus of a good green colour. If possible the frames should be left on the beds until late in spring, and the manure must be left in the trenches until the time comes round to force the same beds again, for as soon as the plants begin to grow they send out their roots into the manure, and, of course, derive a good deal of nourishment by doing so. J. C. C.

Failure in winter Spinach.—Autumn sown crops of winter Spinach have become quite a failure here this winter, and all my neighbours' crops have also failed in the same manner. I have had an opportunity of seeing several large breadths growing in gardens in this locality, and in each case the crops are an entire failure—not a single plant is likely to recover. One grower who has had over thirty years' practical experience, and who is one of our most successful cultivators of vegetables, considers his failure due to dressing the ground heavily with rotten pigsty manure; but his crop seems about in the same condition as that of his neighbours'. This is the first time in which he has entirely failed with Spinach during his experience. Another grower attributes his

failure to dressing the ground with fresh manure from the cowsheds; whilst others, who dressed the ground with ordinary farmyard manure, have succeeded. One large grower always sows his Spinach upon ground which had been used for early Potatoes. In this case, though the ground was manured in spring, every plant has decayed, and that after attaining a size when plenty of leaves could be picked for use. During my experience in growing winter Spinach in many different parts of the country, I have never seen it fail as it has done this year; frequently a few plants fail to grow annually, but not the entire crop. I sowed my earliest crop the second week in August, choosing for it an open quarter in the garden, which had previously been cropped with early Potatoes and Peas, the ground having been manured in spring. The young plants came up strongly, and grew satisfactorily for some time, but after they were thinned in the rows to 6 inches apart, and the leaves ready to pick, they commenced to assume a yellow colour, and ultimately failed. I attributed the failure to a loss of root action, but upon pulling up several of the plants, the foliage of which seemed most decayed, I found the roots to be to all appearance in a healthy state. Upon closer inspection, however, I found at the base of the plants, level with the surface of the soil and round the joints of the lowest leaves, numbers of small white insects, resembling in appearance *Eucharis* mites. About each plant there were dozens of this insect, which had eaten the skin off entirely, leaving only a dry, hard, woody stem. I dressed the plants with slaked lime as soon as I noticed the insects, but without any good results. My second sowing, which was made on September 3, has shared nearly the same fate as the first. Is this disease prevalent this season in other districts, or is it confined to this locality?—WM. CHRISTISON, *Hornwood, Chisholm.*

WINTERING SEED POTATOES.

THERE can be no doubt that even in places where there are ample conveniences for wintering Potatoes in bulk some difficulty is experienced in doing so satisfactorily, and especially so during mild winters, or when they are marked by strong diversities of temperature. Whilst exceeding cold is repugnant, there can be little doubt that a regular, cool temperature through the winter is the best in which to keep Potatoes in a thoroughly quiescent state, and, of course, in the best condition for consumption. The difficulties associated with the storing of Potatoes through the winter begin not so much with early ripening, as with the unnatural ripening induced by either summer drought or the destruction of the leafage and stems by disease. Really well-finished and naturally matured tubers will always keep well, but all those which have come from prematurely checked plants exhibit early impatience to break again, thus showing that there is always instinctive readiness to make second growth or to super-tuberate if later conditions are favourable for such before the crop is got up. For some years it has been a rare circumstance for the plants to hold out naturally to the last, or the tubers to have complete opportunity to fully mature. To that circumstance do we owe some of the complaints now and then heard with regard to want of quality in Potatoes. It is no more possible to have the best quality in two-thirds developed tubers than in fruits which have had but two-thirds growth. That complaint has been more fairly made where, soils being cold and moist, tubers have naturally lacked the maturing influences which heat and drought give.

The inclination to shoot or break resulting from early ripening is a matter of no great difficulty as applied to early sorts. Obviously these are only suited for late summer and autumn use, and only the seed needs wintering. It is impossible to check the natural tendency of the tubers in such a case to push growth quickly, and this fact demonstrates how easy it would be for us to have two outdoor crops of early Potatoes during the year

did we have nine months of real summer instead of but about five. It is a fortunate characteristic of Potato tubers that, whilst it is not possible to repress their innate forces, yet these forces are limited, as is evidenced by the fact that if tubers which have sprouted, say, an inch in length be placed in a dry position and exposed to ample light, the shoots must remain dormant, and, if continued in that position, will so remain for months—in fact, till the tubers die of exhaustion. Thus we have a check upon the earliest of sprouting kinds which enables us to command good, well-sprouted, mature seed at almost any moment. Place these seed-tubers in heat if it be dry and they will still remain quiescent, but bring them in contact with soil or any moist substance, or, indeed, associate them with water, and they make growth immediately. The power of the tuber to produce growth is limited to an inch or so, but when moisture promotes root action, then other forces are brought into play, and growth becomes rapid even in a much cooler temperature. Thus it will be seen that, in the matter of wintering seed Potatoes, we can use them as we like, but only in dry, light positions, from which, of course, frost is excluded.

Whilst late ripening sorts show less inclination to make growth on the part of the seed tubers, they are not less difficult to deal with, on the ground of greater bulk and the necessity for keeping all the tubers fairly well exposed to light and air. It is wise to select the tubers intended for seed, even as soon as lifted, and have them, whilst the weather is open, well exposed to light and air, but not to the weather. The winter's exposure to light thoroughly hardens the skins and matures the tubers, so that with that exposure maintained the sets are in the spring absolutely perfect for planting. Without doubt a Potato store having a north aspect—that is, placed on the north side of a wall—is in an excellent position, because much less subject to atmospheric changes. If the temperature becomes so low that the tubers must be protected by covering with straw or other material, there is the special advantage that the reaction, when a warmer change comes, is slow, and the tendency on the part of the tubers to exhale moisture is very much lessened. With a general even and comparatively low temperature tubers also show very much less desire to sprout when exposed on shelves or stored in tubs, boxes, or pans. Seed Potatoes are, without doubt, best cared for on shelves, straw being placed on the boards to protect them from frost upward as well as downward. Ample facility for turning the tubers is also desirable if stored thickly, and in the case of seed in bulk, it may be sometimes needful to store on shelves some 3 inches or 4 inches deep. In such a case a careful turning should be given once a month, but shoots should not be injured. With respect to eating Potatoes in bulk, without doubt the best receptacles are bins made of stout wooden divisions and fitted with false trellised wooden bottoms, to enable air to pass beneath the bulk of the tubers. Even a couple of inches space is ample. The wood division should have close joints, so that only top covering is needful in case of very severe weather. The front boards should be made to lift out, and thus facility is offered when turning becomes needful.

On wet days a few hours' labour expended in the Potato store is usually well employed, especially if the labour be of a careful sort. Where possible, light should be given through the roof by means of glass tiles, or using stout plate glass; but if the roof is thatched with straw—one of the very best protections from cold as well as heat—then glass can hardly be introduced, unless specially raised frames are provided. A little ventilation is needful, but not much, as the exhalation from Potatoes so stored is very slight. Of course, something depends upon drainage, and if the soil be naturally moist in winter, then efficient drainage should be provided and the floors of the bins should be of concrete. Where a north wall is not available the next best site for a Potato house is beneath trees, which afford protection from frost and from strong sun-heat.

The walls should be 3 feet high from the ground line and 4 feet within, sinking the floor a foot to secure the height; they should be of 9-inch concrete, whilst the roof should be a span one of thatch. Then with a door at either end, ample light and air would be given to the store. A. D.

MUSHROOMS IN WINTER.

THE frosts which we have recently had have reduced the supply of many kinds of open-air vegetables, and those raised indoors are therefore becoming every day more valuable. Amongst these are Mushrooms, which can be used in so many ways, and which give satisfaction both on the breakfast and dinner table. To supply them in quantity should therefore be our aim, and apart from the principal work of making up the beds, there are various attentions that may be given them with good results. It is gratifying to see the young Mushrooms come up in the first flush of their strength, but after the beds have been in bearing for some six weeks they dwindle away, and it may be thought such beds are not worth saving or further attention, but that is a mistake. Good beds may be induced to bear two and sometimes three crops, but by the time the first one is exhausted the manure will generally have become so dry that it is incapable of producing more, and it is by watering the bed thoroughly that another crop is induced to make its appearance. The surface of the bed being generally quite smooth and not in a condition to retain water, it must be watered many times over. The water should be heated to 90°; it should be put over the surface at intervals of ten or fifteen minutes, and it often takes a dozen or more waterings to moisten it through. As soon as this has been effected, the surface should be covered over to the depth of 6 inches or 8 inches with hay, and in a week or so afterwards the young Mushrooms will be observed coming up in crowds.

When beds are formed with rather hot manure, so much evaporation is liable to take place, that by the time the Mushrooms should appear they have failed to come; if no Mushrooms are up in six weeks after spawning, the bed should be thoroughly watered as above indicated, which, as a rule, will have the effect of producing a fine crop. I would never condemn a bed as being a failure until this plan had been tried. A good and abundant supply of Mushrooms may be grown in a temperature as low as 45° or 50°, but it does not answer to have them in this temperature to-day, in 65° or 70° to-morrow, and then back to the cool system the following day. Fluctuating temperatures of this kind make the little Pea-like Mushrooms become brown, and then they cease to swell. The temperature should be studied thus far, that if it is low, let it be low, and if it is high, let it be so; avoid alternations to any extent. Of late we have been trying spawn from several sources, and I am astonished at the result. Good spawn is one of the greatest secrets connected with successful Mushroom culture.

In old houses, woodlice are sure to find their way to the Mushrooms, and as they are very injurious to them, we sprinkle a little salt over the surface of the bed—a good plan. Maggots are more apt to attack them in summer than at this season, but they sometimes destroy them even now, and salt is the best antidote with which I am acquainted. Inexperienced growers might be afraid to put salt near their Mushrooms, as it is no friend of vegetation generally; but my experience leads me to assert that it not only destroys vermin, but also benefits the Mushrooms.

CAMBERIAN.

Good Peas.—How is it that one now never hears of or sees a Pea sent out some years ago, and for a short time pretty frequently met with, under the name of Laxton's Fillbasket? I suppose it must have some fault or faults that would account for its having been discarded, but I must confess I have never been able to discover them. The only disadvantage I can think of is, that this Pea

does not possess the sugary sweetness (when cooked) so much admired by some, but it has a full marrowy flavour that, to my mind, is almost as desirable. In other respects it is a moderate grower, seldom exceeding 3 feet or 4 feet in height, and a very free cropper—at least, that is my experience; but its chief value lies in the remarkable productiveness of the pods when they come to be shelled, every pod that has gained anything like maturity being completely packed with Peas from end to end, so much so, that they are usually not round, but flat-ended sections of a cylinder. This being so, it follows that an equal measure of pods of this variety should produce about twice the quantity of shelled Peas that any other kind would do, and this is just my own experience when comparing it with any other Pea with which I am acquainted. I am fully aware of the grand qualities of Telegraph, Telephone, and other fine Peas of that type; but I am sure that anyone who has charge of a garden will find they might do worse than sow a few rows of Laxton's Fillbasket—that is, supposing that it is still to be had.—B. C. R.

THE BEST POTATOES.

I SHOULD think that there are few at all conversant with Potatoes who would not readily admit that soils have very much indeed to do with table quality and quite as much with crop production. It is very evident that no esculent so thoroughly participates in the chemical components of the soil as Potatoes do, and if certain essential ingredients, potash especially, are absent, the Potatoes will suffer. It is odd, however, that kinds undoubtedly so first-rate in some soils should be bad in others, and *vice versa*, a circumstance which is almost inexplicable, and to be accounted for chiefly, I presume, on the ground that some varieties have better or worse absorbent powers than others in diverse soils. Our West Middlesex soil has an excellent reputation, especially in the London market, and Potatoes from it always obtain relatively the best prices. Thus it is odd to read that Porter's Excelsior, rarely good here, and usually close and heavy-eating, is so good at Cotelstone, and that Covent Garden Perfection, which does so well here, could never be induced to yield more than a very moderate crop. Its brother, Magnum Bonum, always beat it trebly. Here, Woodstock Kidney and Cosmopolitan have always been good, quite up to the best Lapstone form, and rather softer when cooked; whilst at Cotelstone both are pronounced to be inferior. There is no accounting satisfactorily for these eccentricities, for I have had to discard very many varieties that others have esteemed as good when grown in other soils. It is thus very obvious that much injustice may be done not only to a Potato, but also to those peculiarly interested in its reputation, if thoughtlessly it is denounced in one place, while elsewhere it may prove highly meritorious. In giving a selection of best Potatoes, growers whose range of selection is limited naturally write of the few sorts which they grow, pronouncing them the best, whilst there are, perhaps, a score or more of other really first-rate sorts which they have never grown. I have grown literally hundreds during the past twenty years, and have cooked and tasted all from time to time. I could wish now that I had kept memoranda of the cooked quality of each, but I have always been content to judge of the merits of the Potato as served up. Since we got rid of the Americans and many of the older sorts, the average quality of varieties has increased appreciably, and now amongst new seedlings really bad ones are rare. My experience as one of the seedling committee of the International Potato Exhibition, when testing seedlings at Chiswick, satisfied me, as it did the other members of the committee, that there was a decided advance in quality, putting aside cropping, with which feature so many were remarkably endowed. Probably not one half of English gardeners are acquainted with the fine Potatoes which are raised from time to time in this country.

A. D.

FLOWER GARDEN.

LILIES AND THEIR CULTURE.

THAT there are difficulties connected with Lily culture I fancy even the most successful cultivators will allow. How comes it to pass, unless this were the case, that tens of thousands of *Lilium auratum* are annually imported, to bloom for one year and then to die? or why is it that only in favoured localities we are shown good clumps of it that have stood their ground for some years? That they may be seen at Wisley or Duneevan is quite true, but these are favoured spots. This difficulty is evidenced in another way by Mr. Ewbank's complaint a few weeks ago, in THE GARDEN, with regard to *L. neilgherrense*, the finest perhaps of the longiflorum section; and if so experienced a cultivator, in such a locality as the Isle of Wight, finds such difficulty, it stands to reason that it will be still more felt by less experienced growers in less favoured localities. These difficulties are of necessity felt in the rarer kinds, but there is one at least of our commonest Lilies which seems to present a difficulty—the common white Lily. "Do you grow it?" was a question put to me by one of our best cultivators some time ago. "Yes." "And how?" "Well, it grows itself," was all I could reply; and yet numbers of persons have found great difficulty in getting it to succeed satisfactorily.

There are two ways in which Lilies are grown—in pots and in the open air. There is, indeed, a third plan midway between the two, used by my friend Mr. Wolley Dod—planting them out in a pit where they are protected from the effects of the weather, and the flowers retain their purity of colouring. I have seen this tried nowhere else, and obviously it is a plan which few would care to attempt on account of expense. I think most persons would prefer the open air, and where they are successfully done, a border, even though it be of modest dimensions, on which the Lilies peep up from amongst numerous herbaceous plants, is a pleasurable sight. There is a stateliness about them that commands attention; while their graceful curves and clear markings make them especially interesting objects in the flower garden.

There are a few things what make out-of-door culture difficult; in the first place, like as the Rose will not flourish in smoke or the Rhododendron on chalk, so I believe it to be impossible to get the Lily to flourish on clay. I have seen it tried over and over again in the neighbourhood of London, and in every instance it was a sad failure. A friend of mine in the north of London who is very fond of Lilies, and whose garden is situated on the London clay, has tried it over and over again. He has had the beds dug out and filled in with other material; the bulbs have struggled on for a year or so and then succumbed. In the same way they will not endure stagnant water about their roots; this may take place even where the soil is not clayey. Some may, perhaps, imagine that because some are excessively fond of water—for instance, *L. superbum*, which goes by the name of the Swamp Lily—that this can hardly be a difficulty; but let anyone examine any place where our bog plants flourish and he will see that the water is anything but stagnant; indeed, the difficulty of imitating the condition in which they grow constitutes one of the greatest obstacles to their successful cultivation; the water is continually oozing and running away, and constantly in motion from the many little springs in it. Here *Droseras*, *Pinguiculas*, &c., flourish; but when we try to imitate this in our bog gardens the difficulty soon shows itself, so that, although *L. superbum* may grow at the edge of a swamp, it does not

necessarily relish the stagnant water which is sometimes made to do duty for a bog. There is also another slight difficulty connected with them—the tendency that some sorts have to push their shoots underground and come up in quite a different place from that in which they were planted; and so very frequently on going over the borders they suffer from the tender care of those who wish to have their borders tidy. Worms, both earthworms and others, are often a hindrance to their successful growth. I have often found the bulbs pierced right through, and in consequence decay sets in and they perish.

The question of light and shade is one which has excited a good deal of controversy, and each system has had its advocates, who have contended that Lilies must be grown in one or the other. Some sorts, at any rate, seem to me to be indifferent on the subject. The common white Lily is an instance of this. As I drive into our market town there is a row of cottages which I sometimes pass with tiny front gardens, on which in summer the sun beats down from midday until sunset, blistering the paint on the doors, necessitating the closing of outside shutters, and altogether making it evident that it is a sunny spot, yet here I see the white Lily flourishing. Some one has introduced it, and then, as is often the case, has given a bit to his neighbours, and so most of the gardens possess it; but yet in my parish there is a border running up to a cottage facing the north—in shade therefore the greater part of the day—and here are magnificent clumps of it in the greatest luxuriance. It is therefore, I think, idle in the face of facts like these to contend that it—and perhaps many others are the same—requires to be planted in one or the other position.

With regard to soil, it is, I believe, pretty generally recognised that peat and sand suit most Lilies. There are some in which an admixture of loam seems advisable, but it is not, perhaps, too much to say that all Lilies will succeed in peat, and that, therefore, when they are planted, it is well to take out a portion of the soil and fill in with this. How magnificently they do in the Rhododendron beds at Mr. McIntosh's, at Duneevan, Mr. Wilson's, at Weybridge, and all through the Bagshot district is well known; and although we in our humble way cannot imitate these places, yet we can study the requirements of our favourites by giving them a soil that they delight in. With regard to the use of manure, it is universally admitted, I believe, that no bulbous root likes fresh manure, and that with some, contact with manure produces disease and death; it is therefore well not to dig in any where the bulbs are planted. If they are mulched with manure in the autumn it will answer two purposes: it will serve as a protection from frost, and the fertilising part of it will be washed down into the soil, and so tend to strengthen the bulbs. The mention of frost leads me to the consideration of their hardiness; my own conviction is, that very few if any of the Lilies which are so largely imported from North America, Japan, or Southern Europe are tender, and that all will withstand a very low degree of temperature without injury; in fact, I believe, that damp more than frost injures the roots, and this is the opinion of Japanese gardeners, who always speak of damp as the great enemy to their well-being. But if light and shade are a matter of indifference, there is another point in their culture which is not, perhaps, so well decided; are they the better or not for having the ground covered with other plants? In their native habitat they are, I suppose, mostly so covered, and the difficulty of obtaining many bulbous plants is increased by this fact for

you mark where a plant is growing; but when you come to look for it by-and-by you find the whole place covered with rank and luxuriant foliage, and your quest is in vain. This would point to the desirableness of having the ground well covered, and I suppose Mr. G. F. Wilson does this in his wood at Wisley; but how it is to be done in small gardens such as I am now writing of, I do not quite see; and I think we have this to console us, that many plants seem to flourish even where their natural conditions cannot be given them.

Another matter in cultivation the amateur would do well to determine is not to disturb the clumps when they are doing well. We do not care to see single bulbs of a Lily, but rather a grand collection of flowering stems, so as to make a fine display, and it is astonishing what grand clumps a few bulbs will make in the course of a few years. Should they become too crowded, it will be much better to weed out the young growths, so as to give the flowering bulbs more room; but even this will hardly be necessary in most cases, and "let well alone" is a very good motto in such matters. The same may be said, too, of the stems; after they have done flowering it is the practice with some people who are afflicted with the complaint of over-tidiness to cut them off soon after the blooming season is over. This is wrong. Granted that a decaying stem is not a very pretty object in a well-managed garden, yet there are uglier things even than that, while it is undoubtedly better that whatever of nutriment there is in the stem should go to the benefit of the bulb rather than to the manure heap. I would, therefore, advise all stems to be left on until they have completely withered.

DELTA.

THE GREAT REED.

(PHRAGMITES COMMUNIS.)

THIS handsome native plant is well worth cultivation if a suitable place can be given it at the edge of a piece of water or in any damp ground. When well established it will grow 10 feet or more in height. The plumes of black flowers are handsome, and the sharply-pointed, blade-like leaves, which seem to spring with a sort of determined vigour from the slender, slightly-arching stem, give great character to the plant. The leaves when stirred by the wind give the pleasant "swishing" sound common to many of the great grassy plants, such as *Arundo Donax* and the Bamboos.

Double Wallflowers—Something has been said lately in praise of the old-fashioned double Wallflowers as distinguished from the lumpy and coarse German varieties. I may mention that by far the most delightful double Wallflowers I have ever seen or smelt were in the great market place at Verona last March. These were golden in colour, shaded with a little tawny orange, and most deliciously fragrant; leaves and stems delicate and slender, the flowers loosely double, not very closely crowded on the spikes, and almost as large as a crown. Altogether they were greatly superior to even the very best of our old English sorts. Unfortunately, no little plants were to be had, and my movements prevented me from bringing large ones home with me.—G. H. E.

— Much as I admire Wallflowers, I should not advise their being trusted to the anything but tender mercies of one of our English winters. Indeed, it is to the incapacity of the plants to withstand our winters that we owe their present scarcity. Twenty years ago, the old double yellow, the coppery red, and the rich dark one were fairly common; now they are rarely seen in gardens. Whatever may be the case in the milder parts of the kingdom, certainly over a large area few double Wallflowers of the old perennial type

are to be found. If they could be re-uscitated, it would be well for these growing them to propagate young plants by means of cuttings every summer, preserving these as pot plants in a frame or cool greenhouse in winter. I dislike the double German forms as much as "Veronica" does, and think them the reverse of pleasing. The dwarf double yellow Wallflower, mentioned as the Rocket Wallflower, is apparently identical with a kind which I had formerly known as the Whin-flowered, because the blossoms resembled those of the double Gorse, but that went the way of the rest; and I fear this year we shall find that the hardy singles have suffered considerably also, for the hard, heavily weighted snow and intense hoar-frost have brought many otherwise apparently hardy plants to grief.—A. D.

CACTUS AND OTHER DAHLIAS.

Now that the promoters of the Grand National Dahlia Exhibition have decided to introduce in their schedule of prizes a class for Cactus and "decorative" Dahlias, the question arises, what is a decorative Dahlia? Doubtless the framers of this class intended it to include only the Cactus types

Phragmites communis.

so called and any of a similar character, such as the old *pieta formosissima*, which Mr. H. Cannell revived a few years ago, but which was grown in this country before D. Juarez was heard of. The floral committee of the Royal Horticultural Society have occasionally given first-class certificates of merit to Dahlias of the show class as decorative varieties, but not always wisely so, because when they had only the flowers to judge from, no reliable evidence was forthcoming as to the habit of growth of the plant, which is a matter of the first importance. All the bedding Dahlias, selected mainly for their dwarf growth and free-blooming qualities, besides their habit of throwing their flowers well above the foliage and their bright colours, are decorative Dahlias in the best sense of the word, and they are clearly admissible in the decorative class. But it should be understood that no variety that finds a place among the show and fancy Dahlias should be admissible for competition among the Cactus and decorative varieties. Perhaps when the schedule of prizes is issued some limitation will be made in this class, so that as far as possible exhibitors may be able to show on a footing of equality and correctly.

I will now pass in review the section of Cactus Dahlias, but it should be said at the outset that, while many of the varieties look charming in a

cut state, they may have little or no value for garden decoration, because of their tall growth and the grave defect of hiding their flowers among the foliage. A Cactus Dahlia, to be of value as a variety for garden decoration, should be of fairly dwarf growth, not more than 4½ feet high, compact, erect, free branching, free blooming, displaying its flowers well, upright, not drooping, and throwing the blossoms well above the foliage. Add to these flowers of striking colours, so as to be effective in the open border, and we get a model decorative Dahlia. Now let us endeavour to judge some of the varieties of which we hear so much by this standard. Take one of the very best when seen in a cut state, *Cochineal*, a variety that is pretty certain to be exhibited in all the stands at the Crystal Palace, the shaded crimson-scarlet flowers being very bright; but it has the sad defect of mingling together flowers and foliage, and so does not display a good and effective head of bloom at any one time. *Cochineal* is regarded as an intermediate form between the Cactus proper and an ordinary show variety. *Constance*, or the white Cactus, grows fully 6 feet in height, but it must not be taken as a white form of *Juarez*. It is free, attractive, and does not hide its flowers in the foliage so much as *Cochineal*. *Fire King*, or *Glare of the Garden*, for it is found under both names, has small vivid crimson or dark scarlet flowers, is of a fairly dwarf and good habit of growth, displays its flowers well, and is a striking object in the border. *Juarez* is so well known with its scarlet, Cactus-like flowers, that little need be said about it; it is of fairly dwarf growth, but had it the freedom of one of the small-flowered *Pompon* varieties, it would be a perfect decorative Dahlia. Then there is *Mrs. Hawkins* with its pleasing bright, deep sulphur flowers, but it is a tall grower, quite 5½ feet to 6 feet, and has the bad habit of hiding its blooms. Nine-tenths of the people who buy this Dahlia do so to plant it in their borders, and become greatly disappointed at finding it such a tall grower. But then it is a novelty, and that fact sometimes covers a multitude of defects. But it will tell in a stand of cut blooms for exhibition purposes. Mr. A. W. Tait I do not know, but it is represented as having pure white and very double flowers, the tips of the petals being deeply serrated. *Parrot* may be said to be a small form of *Juarez*, with petals somewhat twisted, and of an intense scarlet colour, and it is said to make a good border plant. And what shall I say of *pieta formosissima*? When, a few years ago, we saw that representation of it in Mr. Cannell's catalogue, it seemed certain that we had secured something of a marked individuality of character. During the past three years has anyone seen a bloom of it that compares, except at a disadvantage, with the coloured illustration. Of all tall ugly growers, this is the most ungainly. Early in the season of bloom, the flowers are anything but attractive, but later in the season they are of a better character. But its tall growth will effectually prevent its being kept long in a garden after being once planted. One remarkably good new variety is *Turner's Flambeau*; it is of a bright scarlet colour, grows about 4 feet in height, and is very free and effective, throwing up a good head of bloom, well above the foliage, on good long stems. This is a want in some of the Cactus varieties; their stems are short, and so the flowers do not rise well above the foliage. I think that in requiring six bunches of these in six distinct varieties, a little too much is being asked at the hands of exhibitors, seeing how restricted are the varieties. I think it would be best were this class made to read, not less than three varieties. But much will depend upon whether the bedding varieties are admissible. If they are not, then the competition must be almost entirely in the hands of the trade, for amateur growers will scarcely grow nine or ten varieties. In fact, this number includes almost all the known sorts that are in cultivation. R. D.

Japan Anemones (p. 50).—Of course *Anemone japonica* may have been known in England from Chinese or Japanese drawings long prior to 1845, but I do not think the plant itself was known in gardens ere that date. Siebold was one

of the most successful of all the early Dutch plant collectors, and his old garden at Leyden still contains many Japanese plants. There were several works on the botany of China and Japan published before 1847, in one or more of which this *Anemone* may be figured. It is figured in Siebold and Zuccarini's "Flora Japonica," vol. i., pag. 15, t. 5, a work commenced in 1825 and ended in 1844. It is more than possible that some of the early pottery, textile fabrics, &c., were ornamented with figures of this plant, and that these figures attracted the attention of ladies fond of needlework.—F. W. B.

WHITE DAFFODILS.

I AM so greatly interested in Daffodils, and especially in the white kinds, and so desirous of helping forward their elucidation, that I trust Mr. Scrase-Dickins and others will acquit me of obstructiveness when I say I am unable at present to look favourably on the proposed trial at Chiswick. Having carefully followed all the correspondence on this subject, I must say that the doubts about Chiswick expressed by Miss White six weeks ago (p. 474) have by no means been satisfactorily answered. "Veronica" (p. 497) puts the matter quite the wrong way on. He says that those who think white Daffodils will not grow healthily and well in the Chiswick garden have not proved their case. Possibly not, but the burden of proof lies on the other side. Some of us think that before we spare cherished bulbs from small stocks and go to the trouble and expense of journeys to the London neighbourhood, it should be demonstrated with some certainty that the plants will flourish and display their full character at Chiswick. I have seen no evidence pointing this way: all information I have received points rather in the opposite direction. What proof has "Veronica" that white Daffodils grew well—not only grew, but grew so vigorously, that every one of our many varieties would show its individuality—at Chiswick in the days of Salisbury, Haworth, and Herbert? No suitability of air and soil less perfect than this is a sufficient recommendation of a trial ground. I have always understood that the London neighbourhood, generally speaking, affords anything but a welcome home to white Daffodils. I have myself seen them—with the exception of a very few of what may be called the "half-breed" whites, such as F. W. Burbridge, &c.—looking far from happy in nurseries not so far from Chiswick. It is a very good thing to have a neutral ground for the investigation, but it is an absolutely necessary thing to have a ground which is known beforehand to exhibit the plants in their utmost perfection.

Like "Veronica" (p. 497), I have much faith in deep digging and early planting, but am, nevertheless, led by my own experience to infer that white Daffodils are less amenable than the rest to cultivation where their natural requirements of atmosphere and subsoil are wanting. I think I am proving that in this garden—medium loam, rather flinty, on chalk—where all white Daffodils rejoice immensely in their life, they do best and yield the finest flowers when left alone for at least two or three years, while the other sorts give the best results when lifted every summer. It is very doubtful whether they would take a long lease and settle down in this comfortable way at Chiswick. A well-drained subsoil with no possibility of water standing in it in winter is a chief element of success. Not far from here, the scarce double *cernuus* may be seen growing to perfection in a wild copse among matted Hazel stems (loam on chalk), where I have reason to believe that the roots have been undisturbed for many generations. The finest variety of *cernuus* in my collection came from the long-neglected and overgrown garden of an ancient religious house in Wiltshire, where the old clumps were flowering splendidly, though scarcely to be ex-

tricated from a dense overgrowth and undergrowth of Periwinkles and tree roots. Here, again, the subsoil is chalk. I think I once heard Mr. Elwes say something about white Daffodils succeeding on chalk and among roots, and have read something recorded by Mr. J. Wood about their flourishing among paving-stones, or the like. Mr. Harland, too, found his "Bishop Mann," alive and hearty in the bishop's garden, buried in the growth of a century, or was it 150 years! Mr. Wolley Dod tells me that his Pyrenean collector recommends fibrous, peaty soil for the little wild *moschatus*. All this seems to show that our trial of the white Daffodils, to be successful, must be held somewhere where they are sure of a dry, warm winter bed.

But, besides this, we shall, some of us, I think, want at least two more springs for observing and sorting our plants before we are in a position to send bulbs to the trial-ground, knowing accurately what we are sending. Personally, at least, I should not feel I was forwarding science much if I sent plants away from my garden which suits them so admirably before I had thoroughly watched their behaviour, and made notes of their respective features. I cannot count my white Daffodil labels, for they are under a foot of frozen snow, but they are very many, and not a few of them mark bulbs which will flower here for the first time this next spring.

To sum up, if we are to hold such a trial as that proposed, let it be in a locality which not only has not been proved unsuitable, but has been proved suitable, and do not let us be in a hurry.

While on the subject of white Daffodils I may add that their future seems likely to be interesting. I find many of the best forms to seed freely, and to produce remarkably large bulbs the first year from the seed as compared with the offspring of other Daffodils. As to *pallidus precox*, every flower gives a well-filled seed-pod, but I entirely agree with Mr. Wolley Dod that this variety has features—notably its distinct Allium-like bud—which quite sever it from the section of pure *moschatus*. G. H. ENGLEHEART.

Applethorpe, Andover.

Aster spectabilis.—The colour and habit of this *Aster* are good (p. 6), but "J. W." must excuse me for saying that it is not a *Michaelmas Daisy* at all, as even in this late garden its flowers are over long before *Michaelmas*, and it has a very short flowering period. The merit of *Michaelmas Daisies*, properly so called, is that they make our gardens look fresh and gay in the month of October.—C. W. DON, *Ely Hall*.

New Chrysanthemums.—Is it after all such a serious misfortune that new *Chrysanthemums* should be introduced yearly by hundreds when all are pretty and many very beautiful? What matters it, as our gardens are all the richer? If we want forms solely fitted for exhibition it will be easy to ascertain the adaptability of new ones for such a purpose. I think the floral committee of the National *Chrysanthemum Society* may be pretty well trusted, and if some of its members are traders, at least about two-thirds are not, and all are thoroughly conversant with exhibition *Chrysanthemums*. Thus, intending purchasers of new kinds have some assistance in selecting the best from the great bulk of novelties that annually crop up. I agree that the issuing of so many new kinds with English appellations is a good feature, as these are more acceptable, more easily pronounced and spelled, and generally more pleasing to the ear than outlandish names. Still, I am not so anxious to see the name of the raiser attached to each appellation, because all flowers should depend upon their intrinsic merits absolutely, and not

upon a raiser's fame, or otherwise. Once a plant is put into commerce it becomes practically the property of the public, and the raiser's copyright in either plant or name is absolutely gone. As a rule, all plants have names of sufficient length, without burdening those having to write them also with raisers' names.—A. D.

TREES AND SHRUBS.

THE PURPLE BEECH.

THAT was a just remark of the writer of the note the other day upon the Purple or Copper Beech in Hampshire, when he said: "There appears to be a difficulty in grouping this tree so as to give effect to its contrast with other trees. Most specimens I have seen have evidently been planted in the wrong place." This is a common fault, but a more common and even graver error is that of planting too many in one garden or park. Like all "good things" among trees and shrubs, the Copper Beech has been used too lavishly and too heedlessly planted, even in places of small extent, the result being that, instead of the tree being the means of heightening the effect of a garden landscape, it actually appals one to see its coppery masses of foliage meeting one at every turn. In a garden—not a big one—I saw in the midlands last year Copper Beeches had been planted by the thousand. These were "arranged" in masses, with no regard to proper distance of planting the trees, no heed being taken as to whether they harmonised or contrasted with the surroundings. You saw these masses from every point, and the whole place wore a very coppery aspect.

All thoughtful planters know that the Copper Beech is one of the principal pigments upon the landscape gardener's palette, with which to paint the landscape, and as artists are always careful in the use of their high colours, so in like manner does a judicious planter take care how he distributes his few precious high tones which are so important and telling in true ornamental planting, and so productive of bad results if thoughtlessly planted. It would be a big place that would need a dozen Copper Beeches to embellish it. The same may be said of other very conspicuous fine-leaved trees and shrubs, such, for instance, as the golden Elder and the variegated *Negundo*, both of which have much to answer for in the incongruous effects one often sees in gardens, particularly in small places. They are even worse than the prim conical Spruces, Firs, and Cypresses, or Noah's ark trees, as the children call them. One can tolerate two or three masses of golden Elder about a place, and a few—very few—nicely placed Silver *Negundos*; but when planted profusely, as in some gardens, it gives the place more the appearance of a laundry-yard than a garden.

The grouping of Copper Beeches with other trees requires much thought to do it well. Sometimes one sees happy combinations result from haphazard planting, but it is always best to well consider where to place such important trees. There can be no rule, though there is a principle to act on. A Copper Beech never produces the best effect if any heavy green tree is close to it, neither must it jar with a tree of a similar colour, like that of the purple Sycamore, or purple Birch, though a group of silver Birches could not have a finer setting than the Copper Beech. It never looks well if planted out in the open, where its fall outline can be seen against the horizon. I should always seek for it a background of larger trees. Pleasing contrasts are most effective, such as combining it in, or making it form a part of a group containing *Laburnum*, which makes a charming picture in spring, and for carrying out the contrast through the summer one could associate it with a pale green tree, none better than some of the American Oaks, whose leaves unfold a soft yellow, and getting greener as the Beech deepens in colour towards summer. Couple a Copper Beech and *Quercus spalustris*, and every May you will enjoy such a pleasing picture as any two trees

could produce. These are only a few instances of the way in which this fine tree can be effectively planted. One must always be careful to plant the best sort of Beech, for there is no other coloured-leaved tree in which there is so much difference in the shade of colouring. Some are very inferior to others, having small leaves undecided in colour, neither green nor purple. The finest forms have the leaves very broad, oval in outline, and of a colour like that of Beet. There is also a broad-leaved sort which has reddish purple or coppery leaves, and this also is a distinct and good kind. There is a great difference, too, in the vigour of the trees, and this is all important. Copper Beeches are raised largely from seed in nurseries, but the seedlings do not come true, and in the best nurseries the finest forms are always "worked" on that account. The new pendulous variety of the Copper Beech is likely to prove a valuable tree, though one can scarcely judge of it at present in a nursery stage. W. G.

Mr. G. F. Wilson's Veronica.—In the *Botanical Magazine* (tab. 5965) there is an excellent portrait of the pretty Veronica exhibited by Mr. Wilson at South Kensington on December 7. The portrait was taken from a greenhouse specimen in 1872, before the shrub was known to be hardy; it looks a little more luxuriant than Mr. Wilson's did, which was gathered in the open air in December; but still there can be no doubt about the identity of the two plants. It was named and described in the *Botanical Magazine* by Sir Joseph Hooker as *V. parviflora* var. *angustifolia*, a species intermediate between *V. salicifolia* and *V. ligustrifolia*. In the description it is once by mistake called *V. parvifolia*. Unless the name has been changed since 1872, I think we ought to keep to that originally given by Sir J. Hooker.—C. WOLLEY DOD, *Edge Hall, Malpas*.

Old Elms.—These, like all other old trees, add much to the beauties of parks; but when they get very old they are dangerous near buildings. Some time ago, when carrying out some improvements contiguous to the household here, I was anxious that some decayed Elms should be felled and some more serviceable trees planted in their stead; but as their removal was objected to, we planted our shrubs and finished our alterations, and all went well for some years, until a strong gale came, breaking boughs and overturning trees in all directions, and amongst the rest one of the Elms just mentioned, containing upwards of 150 feet of timber. Had it been taken down by practical woodmen it could not have been felled better, but it played sad havoc among many valuable shrubs. Upon one side stands the church, with buildings upon two other sides, and had the gale carried it or blown it upon any of these three sides there is no telling what might have been the consequence. Upon examination its roots were found to be thoroughly rotten, with the exception of 3 inches or 4 inches of an outside shell and a few surface roots, and I have no doubt that the majority of them were Ivy roots, as the bole of the tree was encased in Ivy, which must have been the means of keeping it in its right position for some time. Where Elms or other trees are standing close to buildings they should be examined, which is easily done by probing them at the bottom.—J. M.

The Sturtias.—Among the numberless trees and shrubs which we have now in cultivation, and for which we are indebted to North America, the two Sturtias stand out conspicuously on account of their intrinsic beauty, interest, and variety. The Virginian Sturtia is one of those plants that have been nurtured in obscurity, so to speak, for the past century at least, for so long ago as the middle of the last century it was spoken of as having been introduced. At that period, when it was a commendable practice to plant arboreta, it seems to have been much sought after, the result being that there has been handed down to us a few grand specimens of it, which, now being matured, display their full beauty. In the rich arboretum at Syon House a large bush of it is one of the most prized objects in the garden, it being probably the finest example of this shrub in Europe. *S. pentagyna* is likewise an old introduction, having been brought from America about a cen-

tury and a half ago. We therefore possess two Sturtias, and another near ally, *Gordonia pubescens*, so nearly resembles them that, for all practical purposes, it may also be considered a Sturtia. The Virginian Sturtia is, indeed, a charming shrub, possessing a flower some 4 inches across, and pure white except the little tuft of stamens in the centre, which is crimson. *S. pentagyna* is very similar, but it has not the red tuft of stamens, and the carpels or insipient fruits are separated, whereas in *S. virginica* they are formed into a flask-shaped organ. *S. pentagyna* is the hardier of the two, inasmuch as its home is more northerly than that of the Virginian species; consequently it is a more important plant for English gardens, although *S. virginica* is really not what one would call a tender shrub. The latter inhabits swampy places or shady woods in its native haunts, for no doubt the plant is grateful for a little shade to screen it from the full force of a Virginian sun; but here it wants all the sun we can possibly give it in order to thoroughly ripen its growth, so as to better enable it to withstand our sharp winters. Unfortunately, the Sturtias are very difficult to propagate, and this difficulty in propagation no doubt accounts in a great measure for its scarcity.—G.

UNHEALTHY ARAUCARIAS.

I NEVER considered that the Araucaria was worth all the thought that "A. D. W." (p. 13) appears to bestow on it. He bewails the disease that preys upon it, as well as the imperfect means of coping with the disease. My remedy would be the axe in the case of big trees and the handbill with the small. If there is one unsightly object more than another in a garden capable of neutralising the good effect of all others it is an Araucaria in a bad way. Except when seen at its best, as at Dropmore, many regard it as an unlovely tree, very odd-looking certainly, but associating or harmonising with nothing in an English landscape. Rather than go to the trouble of reviving one in a bad way, or, as "A. D. W." says, one with half its branches dead or dying, I think the best advice would be—chop it down, for who has seen a sickly Araucaria reeover or even look decent when once it has lost a limb or become browned? I have long since come to the conclusion that the Araucaria is not a tree for general planting, for, as "A. D. W." states, it succeeds only in certain localities and soils; then is it not folly to go so much out of the way to coax it into vigorous growth when we have within reach so many trees that repay us for planting them and far handsomer? The odd appearance of the Araucaria has, no doubt, captivated many who have room for one tree only, and therefore that tree must be an uncommon-looking one; hence it is so commonly seen in forecourt gardens even in towns, and no doubt these trees are often planted unskillfully. But this is apart from the question taken in the broader sense, which is that which concerns the larger class of gardens in which indiscriminate tree planting is a serious matter, seeing that it is costly. Because the Araucaria is a stock plant in all nurseries, large or small, no garden is considered complete without it, and this thoughtless planting of Araucarias everywhere has been the means of spoiling many a garden landscape. The Araucaria, it must be admitted, is a handsome tree when it is seen so finely grown as the Dropmore tree, which is always cited as the finest specimen; but then is it generally known that Philip Frost has cultivated this tree as he would a pot plant? The tons of top dressing he tells you he has put around its roots during the many years he has had charge of it lets one into the secret of Araucaria culture. It is not the soil or the climate of Dropmore that has made the tree what it is, but the attention that Philip Frost has bestowed upon it. But how many can afford to grow trees on his plan? That the Araucaria as an ornamental tree has been, and is still, over-rated, is the opinion of many; that it is not a tree of the future is pretty well certain. The best effect I have seen produced by it was a group in a Surrey

garden on light soil. The trees were of various heights, ranging from 20 feet to 5 feet, and as there were about a score in the mass, they formed one of the chief features of the place.

W. G.

GROUPING CONIFEROUS TREES.

The dotting style of planting is cold, as well as meagre; nevertheless it has its uses; it shows what individual plants can become under difficulties. It also brings individual specimens and species into the sharpest contrast, and thus exhibits their special characteristics in intensified and, one might almost add, exaggerated lights. It has also enabled cultivators to grow the largest number of species and varieties within a given area. But the dotting plan mars every landscape on which it is practised. What play of light, or shadow, or repose could be obtained by a series of dots, even though they consisted of trees faultless in form and symmetry? Trees so disposed might be enjoyed as specimens, but a pleasing landscape, consisting of solitary trees, is plainly an impossibility. Not only, however, is the dotting style inimical to landscape beauty, but it is also opposed to cultural perfection.

Trees and shrubs are gregarious by nature, and if we compel them to grow in solitary isolation we must take the consequences; and we do so in the form of slow and stunted growth in summer, or of ruthless destruction by cold in winter. It is not good for trees to grow alone. Each wind that blows beats against them with full force; the sun and dry air drain each leaf and bough of its rich juices, and, worse than all, the extremes of heat and cold do their worst as regards the exposed roots. This exposure of the roots to direct solar and atmospheric influence is altogether unnatural, and consequently injurious. But there is no need to rest the case on such general statements. It is only necessary to trace the palpable effects of the frost throughout our pleasure grounds, after an exceptionally hard winter, to discover that the single trees are often cut down, while groups of the self-same sorts escape unhurt. The seeming exceptions but confirm the rule.

These exceptional groups killed or injured will be found in a lower situation or a moister locality. In the former the air is colder, as cold air will shoot down valleys into plains with as much certainty as a stone will roll down hill; in the latter the plants are also more tender. Excessive moisture may help growth, but it hinders maturity, and it is maturity that enables plants to withstand cold. Hence it follows that groups may in such exceptional localities be cut down, while single trees at a higher level, if more thoroughly matured, may escape. But let the three-fold conditions of soil, site, and maturity be alike, and the results will be wholly in favour of the groups. It is necessary, however, to bear in mind that there are "groups and groups." It is not only possible, but easy to render groups tender by overcrowding or over-feeding, and when such is the case, groups may be swept away by a frost that will hardly brown the leaves of a solitary tree. It may be well to add that excessive stimulation, from whatever cause, results in weakness, that leaves the plants more liable to injury from cold than more hardy treatment.

My object, however, is to show that the conditions of growth being the same, Conifers planted in groups endure winters better than those dotted about singly. There is more than one reason for this; the tops are warmer and so are the roots. Plants can scarcely realise the amount of shelter that plants afford each other when planted in groups. I know that in a series of experiments made in Scotland, the absolute difference of temperature between the inside or outside of a wood was much less than might have been supposed. But the difference is one of air in motion or at rest, rather than of absolute superiority or inferiority of temperature. The air around and in a group is, as it were, at rest, compared with that against a single tree. Now, air at rest is one of the best known non-conductors of heat, but air in motion steals it from every living or dead substance that it touches with avidity. No doubt this mere motion thwarts, to some extent, the loss of heat by radiation. But, possibly, there is sufficient gentle movement in

the air of groups of trees to effect this purpose; while of the warmth and shelter the trees afford each other there can be no doubt whatever. But I am of opinion that the shelter which they afford to each other's roots and their own is of yet greater importance.

From many years' observation of the destructive effects of cold, I have arrived at the conclusion that most plants are crippled or killed from the roots upwards, and not from the tops downwards. This is what kills isolated trees. The best roots are often considerably beyond range of the tops. Of course, the feeding roots sweep out, and are, in ever-widening areas, in search of new and better food. Just then the frost comes down upon them with full power, and either paralyses or kills them. Old roots might be frost-proof, but young ones are not. The former deprived of the latter are as useless as detached gas or water-pipes cut off from the mains. The collecting roots being crippled or killed, the main ones become useless, and the tree begins to languish and die, or, in other words, is starved by the amount of cold at its most sensitive extremities, which planting in groups would have protected most effectually. There is another powerful inducement to planting in groups.

The dead leaves may be left to protect the roots along with the overshadowing tops. The former, in many cases, would afford the better protection. It is astonishing how many leaves fall off *Coniferae* just before winter; whole barrowloads of withered leaves lie under large trees of *Pinus excelsa*, *P. Sabiniana*, *P. macrocarpa*, and others. Under single trees these are, in most cases, carefully swept or raked up as so much unsightly litter, or are blown away by the wind. This is simply to lay the most sensitive part of the tree open to the cold. In a state of Nature these dead leaves accumulate to such an extent as to cover the ground under the trees ankle deep. They decompose very slowly, and their texture, form, and non-conducting powers are such that a very thin layer of them forms a frost-proof barrier. I have proved this, and no one who has not noted the power of the tops above and leaves below to resist cold could form a proper estimate of their potency. In group-planting there is no temptation to remove the dead leaves, and the wind is powerless to drive them out. Hence trees in groups cannot suffer at the roots, and, as a rule, they winter safely.

F.

White Japan Quince.—The numerous varieties of *Cydonia*—or, as some prefer to call it, *Pyrus japonica* are amongst the most handsome of hardy ornamental trees and shrubs. They exhibit a considerable range of colour, from almost pure white to deep crimson. In size of individual flowers, too, a great advance has been made amongst the cultivated forms and the seedlings raised since the old *Cydonia japonica* was introduced, about seventy years ago. One of the most desirable of these is *Pyrus japonica nivalis*. In this there is no trace of the pink colour which is so prominent in the old so-called white

Pyrus japonica, the large flowers being almost pure white.

Stem-pruning Deodars.—Stem-pruning encourages upward growth, adds variety to the landscape, and is not in the least injurious to the health of the plants. Stem-pruning need not be practised on Deodars till they become 8 feet or 10 feet in height. When of that size the stem should be divested of its lower branches, from 10 inches to 18 inches from the ground, according to the height of the tree; as the upward growth of the tree increases, the stem-pruning may be carried to the height of 24 inches or 30 inches. The effect of the pendent points of branches round the central stem is in some circumstances infinitely more pleasing than seeing the lower branches lying flat on the ground and destroying the Grass below. After pruning the stem of Deodars, as well

completely surrounded with branches; besides, from the greatest cold being on the surface of the ground, it is more apt to injure those lying on the surface than those higher up.—J. M.

OBITUARY.

THOMAS MOORE.

MR. THOMAS MOORE died at his residence in the Botanic Garden, Chelsea, on New Year's Day, in the 66th year of his age. Death has thus removed from our midst one of the best-known and most prominent men in connection with the horticulture of this country. Regret at the death of such a man will be universal, for

his life-long labour in the advancement of horticulture is known, we might say, in every country where a love of gardening is fostered. More than half his life has been spent in literary work connected with gardening and botany, but he began gardening as a boy upwards of fifty years ago, first at Guildford, his native town, and afterwards at Fraser's nursery at Leyton. In 1841 he became Mr. Marnock's clerk, at the time when he was laying out the Royal Botanic Society's Gardens, in the Regent's Park, and he was afterwards associated with Mr. Marnock in the production of a gardening journal, which was, however, but short-lived. In 1848 he was appointed curator of the Chelsea Botanic Garden, as successor to Robert Fortune, so that he has resided at Chelsea for nearly forty years, and has been associated with the chief gardening events that have taken place during that time both here and on the Continent. For the Royal Horticultural Society Mr. Moore has worked most assiduously both in connection with pomology and floriculture. At one time he was one of the directors of the Chiswick Garden, and also examiner in floriculture both to this society and to the Society of Arts; he was secretary to the great International Exhibition and Congress that was held in London in 1866. Of late years

THOMAS MOORE.

as all other coniferous trees, where the branches to be removed are in close contact with the ground, it will be necessary to lay down soil, so as to cover any roots which may be near the surface, in order to protect them from the sun or frost. Unless this simple treatment is adopted, such stem-pruned trees are liable to sustain injury, and blame given to the pruning, and not to the want of this after-treatment which is absolutely necessary, not only with *Conifers*, but with all evergreen shrubs requiring to be cut down. In the case of stem-pruned specimens of coniferous plants, I consider that the bark on the lower part of the stem, when allowed to mature and harden from exposure, is better able to resist cold, and the tree more likely to stand uninjured than it does when

floriculture claimed a good deal of his attention. In the *Carnation*, *Picotee*, *Auricula*, and *Dahlia* Societies he was the chief leader, and the *Dahlia* Society was his especial hobby, the late Mr. Charles Turner and Mr. Douglas being his chief associates in these matters. As an author Mr. Moore has been industrious, for he has written no fewer than a dozen works. The first appeared in 1844, and the last—his "Epitome of Gardening"—in 1881, being a reprint of the article on horticulture which he contributed a year before to the "Encyclopædia Britannica." He will, however, be best recollecting by his works on Ferns, which were his

special study. As an editor he was even more industrious than as an author. The "Treasury of Botany," issued in 1866, is an example of his skill and thoughtfulness, as is also the last revised edition of Thompson's "Gardener's Assistant." For fifteen years (1866-81) he was joint editor of the *Gardener's Chronicle*, and for many years he edited the *Florist and Pomologist*, a monthly magazine which ceased to exist a year ago. At all the leading horticultural exhibitions in London, in the provinces, and abroad, Mr. Moore was a familiar figure. He was considered indispensable as a judge of new plants, upon which he was justly regarded as an authority; indeed, it is not too much to assert that Mr. Moore's knowledge of garden plants was unsurpassed by that of any other man one could name. The above is but an epitome of his chief work. He was a man who won for himself a multitude of friends, by whom his loss will be deeply regretted. In horticulture the good and useful work which he has done will be an enduring monument to his memory.

INDOOR GARDEN.

LAPAGERIAS PLANTED OUT.

THE best way of growing *Lapagerias* is undoubtedly that of planting them out, for although good specimens may, and indeed are, sometimes seen in pots, wherever a surface of any great extent requires to be covered, it is found much more expedient, whenever there is a possibility of doing so, to have them planted in the conservatory or greenhouse border. *Lapagerias* being somewhat shallow-rooting plants, their roots naturally attain a great length and cannot well be accommodated in a pot, and when planted out they annually gain in strength.

When planted out, great shoots are produced from the crown in a similar manner to those formed by *Asparagus*, and these should receive every encouragement; owing to the somewhat horizontal direction that they generally take during their development, they often rise from the ground at a great distance from the parent plant, and in altogether unexpected places; on that account alone a border is preferable to pot culture. When *Lapagerias* are planted out it is beneficial to have them surfaced with fresh soil every year, and under all circumstances the operation should be performed before the new shoots push through the ground. A gentle stirring of the surface of the soil with a hand-fork having been carefully done to the depth of about 3 inches or 4 inches, and the material thus loosened having been removed, the border should be filled up again with fresh compost. A mixture of two parts good fibrous peat, one of coarse silver sand, and, if procurable, a little rubble or a small quantity of broken-up charcoal, is about the best material that can be recommended for the purpose. This annual surfacing has the effect of stimulating the vigour of the plants, as the nutritive properties contained in the new compost are, by repeated waterings, carried to the roots, which derive great benefit therefrom. The new shoots must be carefully watched, and, as soon as they issue from the ground, protected by a piece of zinc formed into a tube about 6 inches high and 2 inches in diameter. This is the most efficient way of preventing slugs from destroying them; all ingredients recommended for that purpose lose their efficaciousness through the damp state in which the ground has to be kept.

After the flowering season *Lapagerias* should be re-arranged on the roof, leaving between their foliage and the glass a space of 8 inches or 10 inches, which is sufficient to enable the syringe to have full effect on them during their growing season, when they require frequent use of it to prevent their being infested with aphides, which, under cool treatment, are the only insects that

attack them. By being trained near the light the wood gets well hardened and produces flowers in greater profusion, but as soon as the flower-buds have reached the size of an ordinary Pea, which is generally about the end of July, the shoots should be untied and allowed to hang down loosely. This gives the plants a better opportunity of displaying the beauty of their blossoms and produces a very pleasing effect, which is also enhanced by disposing the flowering shoots, when they are untied, at various heights.

It may be well to state here that for training *Lapagerias* it is much better to use soft string than either copper or galvanised wire, for while the former material retains, owing to the frequent summer syringings, constant dampness, which is greatly beneficial to the plants, the latter is often the cause of serious disasters through being a conductor of heat, and getting in summer much warmer than the young and tender shoots are capable of enduring without suffering. Abundance of water at the roots is necessary at almost all times of the year, but particularly from March to October, during which period the waterings should be both frequent and copious. The foliage should be freely syringed until the flowers begin to open. Shoots from the plants which were layered in the border last year will be found to have rooted freely, and to have produced independent plants from the eyes which have lain buried in the soil during the past season. These may now be separated from the parent plants and treated as ordinary layers.

CROWEAS AND THEIR CULTURE.

CROWEAS belong to a limited family of evergreen greenhouse plants, introduced from New South Wales, that are of comparatively small, bushy habit of growth, producing their lively dark pink star-shaped flowers, for two or three months in succession through the autumn, at a time when greenhouse-flowering subjects are few. *Croweas* have many things to recommend them to the general cultivator, not the least of which is their easy growth and adaptability for decorative purposes, especially for the conservatory, where by regulating the time that they commence growing a succession of the plants may be had so as to have some in flower from the commencement of August, to be succeeded by others that will keep on until after the close of the year. They will also bear, whilst in bloom, placing in a confined situation in conservatories or similar places much better than most hardwooded subjects; they likewise have the property of flowering freely in a very small state. Plants the first year grown from the usual nursery-sized stock will just bloom as plentifully in proportion to their size as when older. When they get large and are well managed, they are useful for exhibition, if required for this purpose, the nature of the flowers being such that they will bear a deal of knocking about without being bruised or disfigured. They make moderately strong roots, that are not at all delicate or liable to injury from causes that would result in the death of more tender things; yet they do not form them in such large quantities as to need so much pot-room as many plants. All the kinds will grow in loam, and in it, when of a good description, the colour of the flowers is often a little higher; but in peat they generally make quicker progress, and where the latter can be had of a fair character, we should recommend it in preference to loam, using about one-sixth or seventh of clean sharp sand intermixed.

Although the *Croweas* do not require anything above a cool greenhouse temperature to grow them, they are amongst a certain number of plants that will bear and make much more progress by having their growing season lengthened through being started in a little warmth in the winter. Their time of flowering can also be regulated by this. Plants that are thus started into growth in slight heat in February will bloom early in August if required, to be succeeded by others, the growth of which commenced with the advance of the season. Where there is the means of submitting them to a temperature of 50° in the night, with a rise of 8° or 10° by day, about

February, we should advise the young stock to be so started at that time.

Croweas strike readily from cuttings, which should be procured about April from plants that have started in an intermediate temperature in February; put them several together in 5-inch or 6-inch pots in sand, subjecting them now to an ordinary stove temperature, with shade and a moist, confined atmosphere; here they will root in six or eight weeks, when give more air and light. As soon as they are fully rooted move singly to small pots, stopping the points and continuing the warm, moderately close treatment through the summer and autumn, keeping on in the winter in a night temperature of about 50°. In March the young plants should have made enough progress to admit of their being moved into 4 inch or 5-inch pots, stopping each shoot; through the spring and summer give a little more warmth than usual for the generality of greenhouse plants, standing them on a moist bottom, with plenty of light and a little shade in very bright weather, giving a dash with the syringe every afternoon. Winter as before, and about the commencement of the year cut in the whole of the preceding summer's growth, leaving the shoots about 6 inches long from the point where they were shortened to the previous season; tie them out in a horizontal position, and about the time and in the temperature above advised place them where they will receive a fair amount of light, slightly dumping them overhead with the syringe once a day; here they will soon commence growth and be in a condition for potting. They will require a 2-inch shift, with a fair quantity of drainage, using the soil in a moderately lumpy state, and pressing it solid in the pots. Replace the plants in a similar temperature to that they have been in, and here let them remain until the beginning of May, when there will be enough solar heat to keep them on growing without the assistance of fire; after this, they will do along with other ordinary hardwooded stock, requiring like treatment through the summer as to air, syringing overhead, and closing the house or pit they occupy with the sun upon it in the afternoon. They will not need any stopping of the shoots, except such as happen to grow considerably stronger than the rest. The reason that it is not advisable to stop these plants in the summer, as prescribed in the cultivation of most hardwooded subjects, is that if pinched back nothing is gained, as it rarely has the effect of causing shoots to break out several from each, as in the case of most things, but simply stops growth altogether for the season, and hastens their flowering. Where there is not the convenience of a house in which they can receive a little heat early, as above described, all the difference in their treatment required is to pot them later, about April, with the other hardwooded greenhouse plants, and treat through the summer as before advised, but by the latter method they cannot be expected to make so much growth, nor flower so early. When they come into bloom they will make nice little plants for standing on front shelves or in any prominent position.

When their blooming is over, remove the plants to where they will receive ordinary greenhouse treatment as to temperature, air, and water, cutting them back as in the preceding season so as to reduce the shoots to 6 in. or 8 in. in length from the point they were shortened to the year before, and again starting them in a little heat as previously, or if a succession of bloom is required, a portion of the stock may be allowed to commence their growth later on in the greenhouse. This year they will bear a 3-inch shift, using the soil in a little more lumpy state, and keeping the strongest shoots well tied out, so as to clothe the base of the plants, treating them through the season as heretofore. The treatment required during subsequent years will be similar in every way, always cutting the shoots well back before growth begins, or a sufficiently dense, bushy condition will not be maintained. It is not necessary to increase the size of pot beyond 15 inches in diameter, as this will be big enough for full-sized specimens. After the plants have been in pots of this size for a year or two they should be regularly supplied with manure water through the growing season. In this way *Croweas* may be kept for years in a thriving, healthy state.

Azalea mollis.—This Azalea is very valuable for forcing purposes. Plants if potted up in summer and kept out of doors until hard frosts sets in force better than plants otherwise treated, and the flowers are more persistent than in the case of plants newly imported from France and Belgium. This is a fact worth knowing; and as it is found by experience that the varieties of *A. mollis* are not so well adapted for outdoor culture—except under very favourable circumstances—as for greenhouse work, and seeing they are easily managed, they should be extensively grown where there is convenience for forcing. The flowers are of various beautiful shades of colour, and all very showy, and the blossoms are borne in fine trusses, which are often equal in size to those of the Rhododendron. Then the plants are of bushy growth, deciduous, and perfectly hardy. The following are a few of the best varieties: Alphonse Lavallée, bright orange, shaded with scarlet, and spotted with citron; Baron E. de Rothschild, dark red, spotted with yellow; Chevalier de Reali, straw-white, merging into creamy yellow; Comte de Gomer, lovely rose, spotted with orange; Isabella Van Houtte, dark nankeen, spotted with orange; Consul Pecher, rose, spotted with dark orange; Dr. Leon Vignes, white, shaded with nankeen, and spotted with orange; and Scarlet La Grande, orange-scarlet, the best of all in colour. It should be stated that the spots are confined to the upper segments of the flowers. From some nurserymen seedlings of Comte de Gomer, Consul Pecher, Isabella Van Houtte, and one or two other distinct varieties can be had, and if these have been transplanted twice and are 10 inches or 12 inches in height and bushy, they will be found admirable for potting-up for forcing purposes. As a matter of course, seedlings can be bought at a much cheaper rate than the propagated named varieties.—R. D.

Origin of Berberis stenophylla.—Can anyone enlighten me upon the history of this most beautiful Barberry? It is generally considered to be a hybrid between *B. empetrifolia* and *B. Darwini*, and I thought so too until I came across the name in Forbes and Hemsley's "Index Floræ Sinensis." It there states that *B. stenophylla* is a native of Szechuen, and gives Hance as the authority for the name. I once heard that it was raised in the Handsworth Nurseries, Sheffield, and was named *B. handsworthensis*, but that the name was afterwards changed to *B. stenophylla* by Lindley. I find no published statement corroborating this. Possibly there may be two Barberries under the name of *stenophylla*; but I am alluding to the beautiful shrub with long, slender branches and narrow leaves, and which in summer is wreathed with golden blossoms brighter in colour and more graceful than that of either *B. Darwini* or *B. empetrifolia*.—G.

Poetical allusions to Pears.—In Mr. Rivers' paper on Pears, published in your last issue, the lecturer notes that Shakespeare only mentions this fruit once ("Merry Wives of Windsor," n. 5), but in "Winter's Tale," n. 2, the poet mentions Warden's—

I must have saffron to colour Warden pies—

and Warden were undoubtedly cooking Pears (cf. Bacon, "Essay xvi."). Again, Mr. Rivers asserts that Herrick does not mention this fruit. Surely he never can have looked through that poet's "Hesperides"? I find no less than seven separate allusions there to Pears, and he, besides Sir John Suckling, has immortalised the Katharine Pear—

So Cheries bluish and Katherine Pears,
(*The Mourning Blush*, "Hesperides.")

Herrick also mentions the Warden—

Of roasted Warden or baked Pear,
(*The Phoenix*, "Hesperides.")

And to a Christmas custom, in which the Pear is alluded to—

Wissal the trees that they may bear
You may a Plum and many a Pear,
(*Christmas*, "Hesperides.")

Spenser speaks of the Pear in his "Shepherd's Calendar" (March 3), and Chaucer, who perhaps

more than any other poet loved the freshness of spring and early morning, alludes to the beauty of the Pear tree in its full bloom—

She was well more blisful on to see
Than is the new Periwelle tree,
(*Mellors Tale*, "Line 61.")

All who have read the "Canterbury Tales" will remember the incident of the Pear tree in the "Marchand's Tale."—P. E. N., *Upper Norwood*.

NOTES OF THE WEEK.

Begonia socotrana proves itself to be the most persistent winter-flowering of all Begonias. At Kew, where almost every cultivated species is grown, it is the only one that makes a show. There is a group of plants of it that for weeks past have been the feature of the Begonia house. The flowers do not drop, as those of most other Begonias do, but wither away without losing their colour. This mass of rosy pink bloom is very cheerful at this almost flowerless season. When the Socotra Begonia was first introduced it was thought that good things would result by hybridising it, but as yet none of the hybrids raised from it surpass the original.

A pretty winter Heath is *Erica colorans*, and we should include it in a selection of the best winter-flowering kinds. It is a good deal like the common winter Heath (*E. hyemalis*) in growth, and, like it, the flowers are long and slender, opening pure white, then gradually changing to a delicate blush, and dying off a deep rosy red. They are densely produced on the upper parts of the new shoots, and are therefore very suitable for cut sprays; one of these flowering shoots with a frond of Maiden-hair Fern would form as pretty a combination as could be cut in the plant house at this season. There is a variety of *E. colorans* called *superba*, but if this is prettier than the original it is superb indeed. This Heath may be seen among others in the Heath house at Kew.

The winter Honeysuckles.—The two Chinese Honeysuckles, *Lonicera Standishi* and *fragrantissima*, which in mild winters are in bloom before Christmas, seem to be still struggling to open their flowers midst the frost and snow. If we get a spell of mild weather, both will be covered with white bloom in a short time, diffusing their Orange-blossom-like fragrance, as does the *Chimonanthus*, which, by the way, is also behind time this year. These Honeysuckles are perfectly hardy, and will grow and flower well in a shrubbery, but then their fragrance is lost, and their flowers are too modest to attract one to them. The place for them is against a south wall near a frequented walk; then one can enjoy their fragrance, and even the crowds of small blossoms give an interest to a walk round the garden at this season.

Bignonia venusta.—This Bignonia blooms as freely during the winter months in a cool stove as it does in a warmer house. Its flowers, which are bright orange-red, have a particularly cheerful appearance at this season of the year when flowers of almost all colours are scarce. The plant grows rapidly—almost too much so where space is limited, but by a judicious thinning of the growths as they are formed, flowers in abundance can be had in a small space. Here it is planted in a Cucumber bed along with some Gardenias, which occupy one side of a small Cucumber house. On the opposite side Cucumbers are grown, and the moist temperature required for them during the spring and summer months just suits this Bignonia. We grow it in a compost consisting of two parts loam, one of leaf soil, some charcoal and bones, and give it copious supplies of water in summer and occasionally liquid manure. During hot weather the foliage is vigorously syringed twice a day. The young growths are trained over the pathway in the centre of the house, which is a span-roofed one, and thus managed they do not interfere either with the Cucumbers or the Gardenias. The strongest shoots are trained thinly on the wires, and all the weaker ones are removed, thus allowing those retained to get thoroughly ripened, and from their points, and also from the axils of many of the leaves on the current season's growths, flowers are now appearing in profusion. Brown scale is the only insect which attacks

this plant, and an occasional syringing with lemon oil is the best remedy for it. It can also be removed by sponging with soapy water, but when the plant is large this is a slow process.—E. M.

With this communication came magnificent clusters of flowers of this showy old-fashioned, winter-blooming stove climber—a plant too seldom met with now-a-days. In old days it used to be well grown both at Kew and Frogmore.—Ed.

The Golden Scotch Fir in winter.—Whoever interested in trees has seen a good plant of this Pine (*Pinus sylvestris aurea*) must have been struck with its bright golden colour, which eclipses that of the Golden Yew and Golden Lawson Cypress, or any other Conifer. In winter its colour is most conspicuous and most valuable, as it stands out so distinct from everything else among trees and shrubs. On account of the depth of the yellow hue, it does not wear that sickly appearance that many other golden Conifers have, and it seems to possess the vigour of the typical Scotch Pine. I saw it last winter at Westonbirt, and Mr. Holford, who knows how to estimate ornamental trees at their true value, thinks highly of it, particularly for winter effect. There is a specimen of it in Kew Gardens near the main entrance, and though it is only about 4 feet high, it is one of the most prominent trees in that part of the garden. It may not be so rapid in growth as the green, and it will be years before a big tree can be seen of it. It is a tree which nurserymen should take in hand, but it does not appear to be catalogued in English tree-lists yet.—G.

Senecio Ghiesbreghtii.—For want of a better English name, this has been called the Tree Groundsel, yet to associate such a noble plant with our troublesome weed is not right. In all Kew there is not a more remarkable plant in flower than this South African one, which largely helps to make the greenhouse attractive. The plants now in full bloom have erect stems, as thick as a broomstick, with leaves nearly a foot long and half as broad, and crowned by a great flower-head composed of numberless small, bright yellow flowers, the whole measuring some 15 inches across. Every visitor seems to inquire the name of this remarkable plant, and few seem to grow it, or know it even. It is a fast-growing plant, for the specimens in flower are 6 feet or 7 feet high, and yet but two years old from cuttings. It lasts a long time in bloom. It is grown in pots and treated liberally, as it is a gross feeder. Mr. Barron used to grow it very fine at Chiswick, and there and at Kew are about the only places in which we have seen it. Why is it that nurserymen do not take in hand such a plant as this, so that it may come into general cultivation?

The Eucharis mite.—I extracted from a *Eucharis* bulb, the other day, about as many mites as would fill a small gun-cap, and put them in an egg-cup half full of paraffin, where they remained all night. I then looked at them through a binocular microscope and they were quite lively at the bottom of the cup, after being in undiluted paraffin for more than eighteen hours. If I could obtain the use of an air-pump I should like to try the experiment of placing a bulb under the receiver, exhausting the air, and then admitting some poisonous gas. What is the opinion of your readers respecting this suggestion?—IVANHOE.

Mr. Rivers' lecture on Pears.—May I ask you to allow me to say that this was delivered at the usual monthly meeting of the Horticultural Club on December 7.—HOX, *Soc. Hort. Club*.

Names of plants. *H. G.*—Apparently a bit of Spindle tree; send flowers and leaves.—*H. S., Duncester*.—1, *Alantium Capillus-veneris*; 2, *A. pubescens*; 3, *A. concinnum latum*; 4, *A. tenerum*; 5, *A. formosum*.—*Anatour*.—1, specimen insufficient; 2, apparently *Succedebium rapulosum*; 3, *Calanthe nivalis*.—*H. K., East Finchley*.—*Epidendrum ciliare*, *Monodes prunum micolor*.—*E. M., Bishop's Hatfield*.—*Bryophyllum calycinum*.—*G. Barham*.—*Illica laurina*.—The plant which "A. J. C." possesses having an aromatic smell is evidently *Coleus aromaticus*.

WOODS & FORESTS.

ENGLISH FIREWOOD.

Your invitation to a further discussion of this question is specially appropriate when the ground is covered with snow and the thermometer indicates 20° of frost. It is also the season of Yule logs and Christmas and new year's festivities when the blazing wood fires on the hearth or in the grate add a special brightness and a new glow of comfort to friendly gatherings. At such times, but for the spits and sparks, there is nothing like deal firewood, and especially Scotch Fir. It may also be fancy, but I rather think it is a fact that this firewood flies and sparks less in Scotland than in England. Whether the difference—if any—arises from the greater age, superior quality, or increased percentage of resin or turps in the Scotch timber over the English, it seems difficult to say. But my experience of wood fires, which is rather extensive, points to a wide difference, all in favour of the Scotch grown wood. It blazes more freely, burns more fiercely, and gives out more heat than the same species of wood grown further south; and as to brilliancy of flame and pleasant odour, there are few, or no, firewoods that can equal the Scotch Fir. I observe that "C. R. S. D." recommends that any one of the Cedar trees should be stored away for its pleasant smell in burning. He also observes that their wood burns brightly when dry. Neither can hardly be said of the Cedar of Lebanon, which, I fear, there will be an excessive experience of as firewood on account of the recent storms. It is in no way equal to the Scotch Fir for firewood, green or dry, and no Cedar but the common red one is worth burning for its odour, and that is seldom available for firewood.

A year or two ago I called attention to the extremely high merits of Yew as firewood, and am glad to find that "J. C. C." holds similar views. I also agree with this writer's estimate of White Thorn and Holly, if it could only be had in sufficient quantity. He is also, no doubt, right in placing Oak at the head of the list of deciduous trees, with Ash as a good second, and Apple and Pear, could they only be had, as good thirds. As to the fourth, there will probably be considerable variety of opinion. In the north of Scotland and other localities where Larch abounds it is highly prized as firewood. It not only burns well and gives out a good heat, but is easy to prepare, and cleanly to use and store. It also gives out a mild and pleasant odour. Sycamore, Spanish Chestnut, and Beech are almost equal in heat-producing properties; and though there is such a difference in weight between Beech and the other two, it does not last much longer nor give out much more heat. Spanish Chestnut spits and sparks almost as much as many Firs. Horse Chestnut is hardly equal to these for fuel, and is not often found in sufficient bulk for firewood. Elms of all sorts I place last. Most of them are difficult to reduce to proper size and form, and are what the Scotch call "dour" burners—a quality most trying to the tempers of those in a reasonable haste for dinner or to get warm. Perhaps no wood needs so much humouring in the burning as Elm, and few woods are, on the whole, less satisfactory, humour it as we may. A good deal, however, depends on its greenness or maturity, and possibly not a little on the soil on which it is grown and the sort. One more wood should have followed closely on the heels of the Ash, if it should not have succeeded the Oak as second, and that is the Hazel. Where this can be had of considerable size, it leaves little to be desired in firewood.—HORRUS.

—Perhaps my experience on this subject may be worth recording, as we burned wood of all sorts in my youth, partly loppings from a wood in the parish, and partly the produce of our own shrubberies. My father (a tree-fancier well known to the nurserymen of his day) always preferred green Ash or dry Oak-top, but we children liked a fire of Spruce or Scotch Fir, especially the latter, and a bit of Birch was a

rare treat, because it produced so much flame. Elm roots we considered "sulky;" but the worst of all wood was that of Sycamore; nothing would induce it to do more than smoulder.—JUNIA.

WOODLAND NOTES.

RAPID GROWTH OF THE DOUGLAS FIR.—On thinning a patch of the above tree quite recently, curiosity prompted me to measure a few of the individual specimens, these being of twenty-two years' growth, and planted in a free sandy soil, with a considerable admixture of alluvial deposit. One of the largest, but there were many quite as big, contained 38 cubic feet of wood, and measured 30 inches in diameter of stem near the ground level. The average height of the trees is 61 feet, with clean, straight boles that taper gradually from base to top, and an abundance of well-feathered branches. What strikes the careful observer most in these trees is the wonderful difference in general habit as well as mode of growth, the branches of some being as pendulous as those in the typical Weeping Spruce (*Abies Morinda*), while others have a decided erect inclination. In colour of foliage as well as habit of growth striking differences are observable in the same wood, that of some trees being of an intense green, others of a dark, almost black, yew green; whilst others, again, have a slight silvery hue intermixed with the usual colour. These differences are likewise usually discernible in the seed-bed, but most strikingly, perhaps, after half-a-dozen years' growth.

GROWTH OF THE WEYMOUTH PINE.—Intermixed with the above Douglas Spruces are a number of trees of *Pinus Strobus*, or the Weymouth Pine, and which, being planted at the same time, or exactly two-and-twenty years ago, give a good idea of the average yearly rate of growth of this valuable tree in our soil and climate. The average height and general bulk of the Weymouth, although far short of that of the Douglas, is, nevertheless, encouraging, and proves to us that when grown on soil of fairly good quality and of a loose nature the tree makes rapid progress, and produces a nice, clean, resinous timber that should be easily worked and suited for many of the uses of an ordinary carpenter. The stems are remarkably uniform in size, the whorls of branches occurring at regular intervals of about 21 inches, and the bark, which is smooth and unctuous in appearance, is of a pleasant olive green above, but changes to a dull terra cotta on the lower portion of the stem. I have just been examining some boards of the Weymouth Pine, the produce of trees cut seven years ago, and find these, although placed under disadvantageous circumstances, as fresh and sound as when cut, the only difference being that the original light colour has given place to a deep lance-wood yellow. I am quite certain that few persons would recognise one of these planks as home-grown, for an examination and comparison reveal but slight differences between it and that imported from its native country.

THE LEBANON CEDAR AS A GENERAL FOREST TREE.—For planting indiscriminately amongst the general run of our forest trees, the above Cedar is, here at least, not well adapted. It requires plenty of room for spread of both root and branch, else it soon puts on a miserably unhealthy-looking appearance, the leaves being scant and a yellowy green, the branch growth laterally short, stunted, and prone to die off prematurely, thus imparting to the whole tree that half-starved look that is anything but desirable where a healthy state of the woods is of first importance. Hardly a year passes that we have not to remove one or two specimens of the Lebanon Cedar, owing to ill-health, but how caused is a puzzle that has baffled for years our most careful investigation and research. Low-lying, damp ground is not the cause, for others lying high and dry are similarly affected, and if soil be the cause, then that of every description almost must be at fault, for on rough sand, heavy loam, vegetable refuse, shale rock with light, sandy loam at top, as well as carefully prepared peat bog, they have gradually become unhealthy, and ultimately died out altogether. I am not now referring to woodland trees, but rather to those grown as single specimens for lawn and park decoration. Seldom does the disease, or premature death from other causes, attack

trees of less than about twenty years' growth, the first indications being want of foliage, this becoming scant and of an unhealthy colour, and in less than three years old is up, for usually at that stage the tree dies off, unless when growing in a conspicuous position, when usually after the second year the axe is laid to its roots.

LARGE EVERGREEN OAKS.—It may be of interest to at least a few correspondents to know that there is growing on Taly Bont farm, midway between Bangor and Aber, a very fine specimen of the Evergreen Oak that stands about 50 feet high, measures 10 feet in circumference of stem, and has a diameter of spread of branches covering 39 feet. Standing alone, with no kind neighbouring clump or wood to guard off our dread south-western blasts, and with a well balanced head of the richest and greenest of foliage, clearly points out how well adapted this valuable tree is for high lying, wind-swept districts. But not only as a hardy subject is the Evergreen Oak well worthy of commendation, for as an ornamental Evergreen that imparts both warmth and character to the adjacent surroundings it has certainly few equals. Large as the above specimen may seem, it fades into insignificance when compared with those of the same kind growing at Peniarth, County Merioneth, and which the following inscription on a beautiful plank of this wood, sent to Lord Penrhyn from the owner of the Peniarth estate, in 1868, and now preserved in our wood collection, but too plainly shows:—

This wood is a piece of one of the great Evergreen Oaks at Peniarth, County Merioneth, blown down in October, 1850, the same night on which the *Royal Charter* was wrecked on the east coast of Anglesea. The largest of these trees was 47 feet high, 6 feet in diameter (21 feet in circumference), and 17 feet from the ground 11 feet in circumference.

1868. W. W. E. W.
The plank in question, although only 20 inches long, 7 inches wide, and an inch thick, weighs fully 5½ lbs. It is of a pleasant walnut-brown, marked with black bars longitudinally, these again crossed, nearly at right angles, with rather broad, wavy, dark brown bands, thus rendering the wood, but particularly in a polished state, of a rich and desirable tint. The idea that this beautiful graining and density of the wood is characteristic of the Evergreen Oak in general must not, however, be for one moment entertained, for it is only the largest and oldest of trees that produce as heartwood anything akin to the above.

EARTHING UP TREE STEMS.—This should never be tolerated, unless, indeed, it is immaterial whether the trees live or die. Not long ago we had some experience of the evils of such—Birch, Alder, Oak, Larch, and Scotch Firs being killed outright, and that in a very short period of time, by the embanking work carried out in the formation of a railway line. At the time it was, no doubt, thought that these living trees would act as first-class props for the embankment, but in less than two years every tree that had a stem covering of 4 feet and upwards was killed. This should be a warning to contractors to first of all remove every tree that may come in contact with the earth thrown together in embanking before the work is set about, for such work cannot be satisfactorily carried out afterwards, unless at great expense and at considerable loss of timber as well.

WOODLAND DRAINAGE.—In a season like the present the effects of a thorough system of drainage are only too apparent; whereas the evils caused by neglect of such should act as a future warning to every forester not to neglect so important and useful an operation. Ground that is excessively damp cannot produce healthy timber—in fact, if we would but take Nature as our guide in this matter we will find that a free, light loam on a porous subsoil produces the largest and finest quality of timber. It, therefore, behoves everyone in charge of woods and plantations to look well to whether or not the ground is relieved of superabundant moisture. Open ditches may be cut in old woods where the Moss clad trees indicate that too much moisture is present, but in doing so, care and forethought must be exercised in choosing the line of drains, so that the dampest ground may be traversed; as well as that in cutting the drains they may have been marked off at such a distance from the tree stems as to injure the roots of these as little as possible. A definite

system of drainage is not required in such cases, the best plan being to open good wide ditches wherever the state of the soil and appearance of the trees indicate that such is needed.

PINUS LARICIO AS A FOREST TREE.—All along we have strongly advocated the extended use of the Corsican Pine for forest planting in this country, and the eagerness with which nurserymen are getting up a stock tells but too plainly for what particular tree most demand is anticipated in the future. Experiments have been carried out all over the country, from the cold, high-lying lands of Scotland to the low-lying plains of Southern England and Ireland, and in every case the anticipated news reaches us that amongst the various Pines that have been tried none seems better suited for the soils and climate of this country than the one in question. It always does me good to have a walk through a thirty-acre wood that was formed on a bare, wind-swept moor at a considerable elevation above sea level to see how the Laricio braves the piercing blasts to which that hillside is fully exposed, and there puts on a freshness and greenness of foliage tint that even the ozone of our seaside woods cannot impart. Many trees have we cut up for boarding, &c., and it pleases us well, being firm and close grained, well impregnated with resin, and capable of being readily and easily worked. The Laricio has a very bad fault, but only the one that I have yet found out, and that is it transplants badly if proper care has not been expended on its early training so as to produce an abundance of fibrous roots. By transplanting it when two years old, and annually afterwards until planted out permanently, we have quite overcome this evil, but to treat the Laricio as we do the Larch, Scotch, and Spruce will never do. Plant the Laricio out permanently at a young age, say three years, and if the above directions have been followed few deaths will occur. A. D. W.

SCOTTISH ARBORICULTURAL SOCIETY.

At a meeting of this society, which took place at Edinburgh, Dec. 23, as reported in the *Scotsman*, it was agreed that the competition essays and reports for next year should be as follows:—

Class I.—For Open Competition.

1. The best and most complete original plan, accompanied with specifications and estimate, for the erection of a forester's cottage.
2. Essay on the comparative value of the newer Conifera, as ornamental or timber trees, in Britain, with date of introduction.
3. Report on the effects of the great gales of the last twenty-five years on the woods and forests of Britain. The report to give the date of gale and statistics of trees destroyed.
4. The history and details of management of the plantations on an estate for a period of not less than twenty years, giving the acreage, annual receipts and expenditure per acre.
5. Report on the comparative value of the different timber trees grown for profit in Britain, with rate of growth of each species in a given time.
6. Report on the plantations of which the competitor is forester. A medal to be awarded for the best report from England, Scotland, and Ireland, and competition to be confined to each country. Reporter to state the extent of plantations, the kinds of timber grown, soil, situation, age, management, &c.
7. Essay on the present state and future prospects of arboriculture in the county in which the competitor resides.
8. Essay on the best system of managing Oak plantations and Oak coppice.
9. Essay on best method of rearing underwood for game coverts in high forest.
10. Report on Conifera produced from home seed as compared with plants from foreign seed.
11. On the natural reproduction (by self-sowing) of forest trees.
12. Essays on the advantages of forming belts of plantations on hill pasture land; the proper width, the best system of draining and fencing, and the most suitable varieties of trees to be given.
13. Essay or report on an arboretum, with plan.
14. Report on the old or remarkable trees on the estate where the competitor resides, giving correct measurements of the circumference of the trunk at 3 feet and 5 feet from the ground; the height of the bole, the total height of the tree, and its cubic contents to 8 inches in diameter. Photographs or drawings to accompany the report.
15. Report on timber grown in Scotland and its uses. The writer to state the principal markets for the various classes of timbers, and the use to which such timber is generally put, with other details.
16. Essay on the best methods of utilising small wood in the manufacture of fancy-wood articles, turnery, &c.
17. Essay on the best method of seasoning different timbers.

19. Essay on any disease incidental to forest trees.
20. Report (from personal knowledge) on the forests of any British colony.
21. Report (from personal knowledge) on the forests of the United States of America.
22. Report on the system of forest management in any foreign country.
23. Essay or report on any other subject connected with arboriculture.
24. For a new invention or a marked improvement on any of the implements used in forestry (models or implements to be accompanied by a report).

Class II.—For Assistant Foresters only.

1. Essay on the formation of plantations. The writer to describe all operations necessary for laying out, planting, and managing plantations for the first twelve years.
2. Essay or report on the best method of renovating overgrown shrubberies. The writer to state the treatment required for the various species of plants.
3. Report on the management of a home nursery.
4. Essay on the best size of plants, and method of planting to produce the best results in different soils and situations.
5. Essay on the formation and management of live fences.
6. Essay on the best dead fence (iron, wire, wood, or stone), taking into consideration economy, efficiency, and durability, and detailing the method of erection and cost.
7. Essay on the peeling and harvesting of different kinds of British bark used in tanning.
8. For the best and approved model in rustic work or in ornamental woodwork of any subject designed and executed by the competitor. Model not to exceed 6 feet in height.
9. For an essay or report on any other subject connected with arboriculture.

The prizes offered in each case are gold, silver, and bronze medals, or their value in money, ranging from £5 to 10s. In connection with No. 7, Class II., a remark was made by the chairman, that foresters were greatly handicapped in this country in preserving their bark by the weather. Mr. D. F. Mackenzie, Morton Hall, said there was no doubt that the tannin was washed out of the bark when it was exposed to the rain. The chairman said that the bark should be dried under cover. A tanner had said to him that more Scottish bark would be used if that were done. The Americans had tried sending over the tannin extracted from the bark in barrels, but it had been found not to work so well. It was announced that Her Majesty had given permission to the society to visit the woods and forests at Balmoral during the first week of August, 1887.

A note was also read from Mr. John Michie, forester, Balmoral, one of the members of the council of the society, stating that he should be glad to assist in the carrying out of the excursion so far as may be in his power.

THINNING FOREST TREES.

THERE is, perhaps, no other branch of more importance in the successful rearing of timber trees for profit than a thorough knowledge of the art of thinning, and, perhaps, there is no other branch of tree culture so little understood, or, at all events, that practical men are more divided in their opinions as to the proper mode of carrying it out. Some say, "do not thin at all, leave that to Nature, and she will do the work infinitely better than we can do." These advisers generally commence their argument by asking, "Who thinned the natural forests—the source from which we derive the finest and best quality of timber?" Now at first sight these arguments appear to be conclusive, and there can be no doubt that by studying Nature we can learn much; at the same time when once we become familiar with her ways, we can sometimes find a favourable opportunity of assisting her in her operations, and by acquiring a knowledge of her economy, and where and when to apply that assistance rests the pivot of the whole argument. As, for example, in thinning a natural plantation of Scotch Fir some years ago, I found a patch of trees in one portion of the plantation about 30 feet high, and growing at a distance of some 10 inches or 12 inches apart. These trees were straight, and free from branches with the exception of small bushy tufts at their summits. Now, had these trees been thinned in early life, there can be no doubt that they would have attained the size of useful timber; whereas by leaving them to Nature they were only fit for paling rails or other similar purposes. These trees, being all about one size, grew up like a crop of Corn or Wheat, but had they been of different sizes the results would have been widely different, as the larger trees would then have killed their weaker neighbours, which is Nature's system

of thinning under ordinary circumstances. This may be taken as a fair illustration of the difference between natural forests and such as have been planted. The trees in the latter are generally nearly one size as regards height, whereas the former are of different sizes, except in some isolated patches such as I have referred to. Now when the larger sizes of trees in the natural forest kill the weaklings in their immediate vicinity, the latter are never removed, at least as far as Nature is concerned, so that they crumble away and fall to the ground by degrees; consequently no sudden climatic change takes place in the forest, as the work of pruning and thinning goes on at such a slow pace that the trees left never feel the want of such as have been killed, and the result is that we never find any bark-bound trees in the natural forest, that is trees whose bark contracts and prevents the free circulation of sap, such as is caused by sudden exposure.

The foregoing is a brief description of Nature's system of thinning. I shall now hastily glance at the system pursued by the forester, and in doing so I think I should not be far wrong in stating that in too many cases plantations suffer considerably before thinning is commenced, the trees becoming too crowded. Care is necessary at all times, but more especially in cases where thinning has been neglected too long, not to admit too great a current of fresh air at once into the plantation, which would have a very injurious effect upon the health of the trees, and lay the foundation for a series of diseases, from the commencement.

On exposed situations and under such conditions I have found it a good plan to stem-prune such trees as were to be removed by cutting off two or three tiers of the lower branches, by which means the permanent trees are allowed room for development, and the others can then be removed in due course as required. This system is more in accordance with that pursued by Nature, as the temperature of the plantation undergoes less change than would be the case were the trees cut and removed at once. I have practised this system on exposed situations for many years, and can recommend it with confidence under such circumstances; nor do I remember seeing any of the permanent trees so dealt with become bark-bound, or fall into a state of premature decline.

Under such conditions it will be seen that thinning should be carried on gradually and conducted on rational principles, special care being taken never to open up the plantations too much at one time to admit a sudden rush of air through the trees, otherwise the latter are sure to suffer damage to a serious extent.

Trees growing on different soils and situations show considerable diversity of size and strength in a given period of time, so that it is necessary to take all such circumstances under consideration when commencing to thin. Those, again, on high exposed situations should be treated cautiously as regards thinning, whereas such as are growing in sheltered situations in the interior of the plantation may be allowed more space than the former without risk of injury. Another point of much importance in rearing timber for utility, and one which should never be lost sight of, is to remove all crooked, weakly, inferior trees, and leave such as are strong and healthy for the permanent crop. Sometimes this system may interfere to a certain extent with the regularity of the trees left upon the ground as regards their distance apart, yet, although it may sometimes happen that the best tree is not in the exact spot where it could be wished, yet for the welfare and prospective value of the plantation the best should always be retained. No doubt if the trees in a plantation were all equally robust and healthy, then such should be thinned to a regular distance apart; but it is seldom that such is found to be the case, and although trees may appear to be nearly uniform, yet the practised eye of the forester can often detect a difference, when he will then select accordingly. J. B. W.

Timber sale.—About 500 Elm trees were sold at Wantage, Berks, recently, at prices ranging from 6d. to 9d. per foot. The quality of the timber, with a few exceptions, was scarcely up to the average on account of the trees being knotty, owing to constant lopping.

No. 791. SATURDAY, Jan. 15, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ORCHIDS.

DOES ORCHID CULTURE PAY?

I HAVE had to do with Orchids ever since I began my gardening career in 1852, good collections, for the period, having been grown in all the establishments I passed through, and more or less under my charge. I long ago formed the opinion that as far as the appearance of Orchids went, when not in bloom, they were anything but ornamental in the ordinary sense of the word. They are queer-looking objects, and sometimes interesting in appearance, but I have never heard anyone venture to assert yet that they were handsome subjects in the sense that ornamental plants are regarded. In short, to speak the truth, a shelf of mixed Orchids has about as scraggy an appearance as any collection of plants could well have; and as in collections generally the blooms are, as a rule, few and far between, this scraggy aspect may be said to be the normal condition. I am not speaking of trade collections, in which monetary considerations compel good culture, and where the flowering plants are gathered from among thousands of stock to make a display for the public, but of collections in general, which run perhaps from a hundred to two or three hundred plants in private places. Such collections are, as a rule, unsatisfactory and unprofitable—not regarded from a merely monetary point of view, but as decorative subjects in any form. I had lately some talk with a plant-grower in a moderate way, and, concerning Orchids, he said he commenced their culture with enthusiasm, from what he had seen at flower shows and in nursery collections, and gave it up in disgust. His collection was managed as well as such collections generally are, but he had plants that had never flowered from the day they came—several years, many that flowered but sparingly, and only a few that flowered fairly well. Altogether his Orchids were the least satisfactory plants on the place, and he "swapped" them, as he said, "for a collection of anything that would live and flower with some degree of certainty, and that he could gather a handful of flowers or leaves from without fear or hesitation when he wanted them." This he now succeeds in doing, although the value of the "swap" on his side was a flea-bite compared with what he paid originally for his Orchids. This view is being adopted now by a good many proprietors and their gardeners; by the first, because of the expense of culture and poor results, and by the latter because of the difficulty of giving the plants the attention they need with the reduced labour which is now the order of the day in many old gardens. The rage for Orchids began in the large gardens of the wealthy throughout the country, and later extended to those in the suburbs of towns. Their culture is now practically discontinued in the former, or, at least, is at a standstill, and the town gardens will follow suit, as they have hitherto done in gardening matters. Nurseries are at present crammed with private collections of Orchids reluctantly taken in at a great sacrifice to the private grower. I do not say that there are not a few Orchids that it will pay to grow for flower, but the number of these can be summed up on the fingers of both hands. What is true is, that collections of numerous spe-

cies and varieties as now grown by the average cultivator are practically a failure, and none are so ready to own it as the trade whose prospects of business depend largely on the mortality among their customers' collections. "What becomes of them all?" I asked a nurseryman not long since, and the reply was, "Oh! they are killed, or die from some cause or other," and he was not far off the mark, judging by what we have seen. For those who wish for plants in flower, in quantity, under glass, the choice lies between stove and greenhouse plants and such hardy subjects as can be grown in pots; Orchids are out of the question. True, their flowers are pretty, and some sorts last in perfection a long time, but these advantages are lost in other ways. I fear that hitherto Orchids have greatly hindered the culture of many other subjects of far more value to the gardener. A house of Roses alone, for example, can be put together for as many pennies as it would cost pounds to fill it with Orchids, and I would like to know anything better than a good supply of Roses of the different beautiful kinds now in culture between December and May. Where the plants receive the most ordinary care they produce blooms in abundance to supply not only the house, but to give away to the proprietor's friends, giving pleasure both to the giver and receiver. Yet Rose culture under glass is as yet a comparatively neglected art, even in those gardens where Orchid culture is but unsuccessfully attempted on an extensive scale. And the same could be said of many other subjects, such as Azaleas, both tender and hardy, Rhododendrons, Camellias, as well as other shrubs and plants well adapted for culture under glass. Under all these circumstances I have somewhat reluctantly come to the conclusion that the popular Orchid is neither a remunerative nor a satisfactory subject to cultivate under ordinary circumstances in private gardens for a supply of flowers, whether on the plant or in a cut state, and that for such purposes many excellent and in every way better substitutes can be found. W.

CALANTHES AND PHAIUS.

THESE are two important genera of orchidaceous plants, and so nearly related to each other, that some interesting crosses have been obtained from them. In each case the seed-bearing parent, *P. grandifolius*, has produced a *Phaius* and not a *Calanthe*, although the progeny has been intermediate between the two. It is twenty years since *Phaius irroratus* first flowered. It is the result of a cross between *P. grandifolius* and *Calanthe nivalis*. Subsequently a cross was effected between *P. grandifolius* and *Calanthe vestita rubro-maculata*, and produced *P. irroratus purpureus*. The first of these bore white flowers, with the exception of the throat, which is pale yellow. Another form which has just flowered has been obtained by crossing *P. grandifolius* with *Calanthe Veitchi*. This has borne a noble spike, furnished with fifteen flowers, each 3 inches across, and very beautiful. The sepals and petals are white externally, and flushed with pale pink inside; the undulated lip is whitish, with a rosy pink margin, and the throat yellow. It may not be botanically distinct from *P. irroratus*, but it is sufficiently so for garden purposes. The intermediate character of these interesting crosses is noticeable even in the habit of the plants; they have not the decided evergreen character of the seed-bearer, nor are they decidedly deciduous, as in the case of the pollen-bearer. Of the last-named it is unfortunate that so few seedlings were raised. Only one plant was saved; and propagation, by severing one or more back bulbs from the main body of the plant, is but a slow process. It might be a question of some importance to know whether seedlings could be raised from any or all of these bi-generic crosses by using their own

pollen. Their culture is certainly not difficult not more so than that of *Calanthes* or any other stove plants; they grow very freely, and flowering as they do during the winter months, they are certainly valuable.

The seed-bearing parent of these hybrid Orchids, *P. grandifolius*, was well known in this country more than a hundred years ago. It was introduced from China about the year 1778, and was grown many years subsequently under the name of *Bletia Tankervillei*. It was also described in the *Hortus Kewensis* as *Limodorum Tankervillei*. Could such a handsome Orchid be brought forward as a new species, it would create quite a furore amongst orchidists. As an exhibition plant it was well known twenty-five years ago, but it usually flowers in March and April. There is an excellent coloured illustration of it in the *Botanical Magazine* (tab. 1924) published in 1817. There are two more species in cultivation, or probably merely sub-species of this, viz., *P. Blumei* and its variety *Bernaysi*, a native of Queensland, also *P. Wallichii* of Lindley, an Indian species. These are tall-growing, handsome Orchids which succeed best potted in loam, leaf-mould, and a little decayed cow manure. I have also found that they thrive well when spent Mushroom manure is put in the compost. The introduction of the handsome *P. tuberculatus* and *P. Humbloti* a few years ago marked quite an era in regard to this genus. These last-named kinds require a very warm atmosphere well charged with moisture, and Sphagnum Moss and a little fibrous peat to grow in instead of loam. They succeed well in some collections and in others they refuse to grow at all, although the greatest care is bestowed upon them. They may be of very great value as seed or pollen-bearers to cross with the *Calanthes*.

The latter have been greatly improved during the last few years by numerous additions, some of the best of them being English-raised hybrids. The finest pure white I have seen is a variety of *C. Veitchi*; the formation of the flowers, length of spike, and whole character of the plant are the same as in *C. Veitchi*. A recent seedling now in flower in Messrs. Veitch's nursery at Chelsea has also very long spikes, with pure white flowers 2½ inches in length by 2 inches wide; this was raised by crossing *C. vestita lutea* with *C. nivalis*. There are also in flower some very distinct pale coloured types, such as *C. lentiginosa*, also a rose and pale red form of that species. These, I believe, were raised by crossing *C. Veitchi* with *Limatodes rosea*. The original winter-flowering species which have in years gone by done such good service cannot yet be dispensed with. Of these there are two groups, both introduced to this country by Messrs. Veitch. Their history is as follows: *C. vestita* (three varieties) was sent to their Exeter nursery from Moulmein in 1848, and the variety with the yellow blotch on the lip was figured in the *Botanical Magazine* (tab. 4671) as *C. vestita* simply; these flower early and continue in bloom up to the new year; indeed, we have them in full bloom now (Jan. 8). *C. Turneri* is quite a distinct species, and was sent by Mr. Thos. Lobb from Java; of this species there were two distinct varieties. *C. Turneri* has a rosy red blotch on the lip, and was the first to flower; the other variety flowered subsequently, and was altogether pure white; it received the name of *C. Turneri alba*. Both flower later than the true *C. vestita* section. *C. Veitchi* flowers at midwinter, and its rosy red flowers contrast well with those of the light-coloured forms. When the flowering period of the deciduous species is well over, the evergreen species are quite ready to take their place. Of these, *C. veratrifolia* is the best, and it is a species familiar to most growers of stove plants. Its flowers are of the very purest white, produced very freely on erect flower-spikes, and the spikes continue in full beauty for two months at least; unfortunately, they are not well adapted for use in a cut state, as they fade in twenty-four hours. This species can always be depended upon to flower in May and June. *C. Masuca* is not so well known, nor does it make

such free vigorous growth, unless in extra good condition. There is a type named *grandiflora* which produces its spikes quite 3 feet high. *C. Domini*, quite a charming hybrid, belongs to the above two species, and requires very similar treatment. Sir Trevor Lawrence exhibited a wonderfully fine specimen of it a few years ago with at least a score of strong spikes on it. The peculiar lilac tint of the sepals and petals is very attractive; the lip is purple. The yellow *C. curculigoides* is a plant to dream about. I have never been fortunate enough even to see it, but it has evergreen leaves and much resembles *C. veratrifolia*, except as regards the colour of the flowers.

The evergreen species of *Calanthe* require the same treatment as the deciduous kinds, except in regard to water. When at rest, they require no water at all at the roots; whereas the others must not at any time be allowed to get quite dry, even in winter. In potting, fill the pots quite a third of their depth with drainage, and over the crocks place a layer of fibrous turf from which the clay particles have been well shaken. A little broken charcoal may be mixed with the potting soil, which should be pressed into the pots moderately firm with the fingers, finishing off the surface as level as for a *Pelargonium*. If the loam is of a clayey character, some coarse sand ought to be mixed with it.

Greenfly gets amongst the flowers if the plants are not fumigated before they open. Brown scale will also attach itself to the leaves, and must be washed off with a sponge and soapy water. We have also had to deal with yellow thrips on them; these, however, succumb to an infusion of tobacco liquor.

J. DOUGLAS.

Lælia anceps.—Numerous varieties of this showy Mexican Orchid are now flowering in Mr. Horsman's Marks Tey Nursery, at Colchester. Amongst the most remarkable forms observed were *Percivaliana*, with its beautiful purplish magenta and white lip; the large and deeply-coloured variety known as *grandiflora* is also a chaste variety; whilst in *coccinea* we have perhaps the most intensely coloured and brilliant form of *Lælia anceps* yet seen.

Dendrobium Fytchianum roseum.—The normal form of this elegant *Dendrobium* was introduced from Burmah many years ago, and was figured by mistake in the *Botanical Magazine* under the name of *D. barbatulum*, from which, however, it is abundantly distinct. It has pure shining, snow-white flowers, which are produced from five to ten together on terminal racemes. In the new variety *roseum*, the white is suffused with a lovely tint of warm rose. This, together with the fact of its being a mid-winter bloomer, will considerably enhance its value. We recently saw it in bloom in Mr. Williams' nursery at Holloway.

Odontoglossums at Chelsea.—These lovely mountain Orchids are now making a rich display in Mr. Bull's nursery; amongst the varieties of *O. crispum* the colours vary from pure white to richly spotted white, and to deep rose colour. There are also quantities of exceptionally fine forms of the *majus* variety of *O. Rossi*, whilst *O. Pescatorei*, which used to be looked upon as a spring-flowering kind, may also be found displaying its chaste white flowers, blotched with purplish magenta on the lip. The Lily-of-the-Valley-like flowers of *O. pulchellum majus*, if not very large, are of the purest white, and disperse a delicate perfume. Amongst other *Odontoglossums* which maintain so much gaiety here are quantities of the richly coloured *O. leopardinum*, *O. Roczli*, *maculatum*, *Cervantesi*, *gloriosum*, *madrense*, and *Erstedii majus*.

Calanthes at Holloway.—In spite of the fogs with which London has been lately visited, there are more flowers open on the *Calanthes* than on any other Orchid. They are just now very fine at Holloway, their long arching spikes of bloom having a graceful and beautiful effect. The

most noteworthy kinds are *C. Veitchi*, the red and yellow-eyed forms of *C. vestita*, *C. Sandhurstiana*, a desirable plant, being a hybrid raised between *C. rubro-oculata* and *Limatodes rosea*. It produces very long spikes, and bears quantities of flowers, which are of a richer and deeper shade of rosy crimson than those of *C. Veitchi*. On the lip there is also a beautiful eye-like spot. *C. Regneri*, a species introduced from Cochin China, proves to be a charming addition to this family; the sepals and petals are white, whilst the lip is deep rosy pink.

Compærtia macroplectron.—This elegant little Orchid is now flowering in various places about London, and very attractive its flowers are. They are a soft rose, and on the spreading, almost square lip there are numerous dotted lines of rosy-red. There is also a very long spur, which is of a pale rose colour. In some varieties we have observed that the whole surface of the lip is covered with red dots. *Compærtias* are somewhat rare in collections, their cultivation not being apparently understood. We have found the scarlet-flowered species (*C. falcata* and *C. coccinea*) to thrive best upon blocks, in just the smallest quantity of *Sphagnum Moss*. Treated in this manner, they produce quantities of roots which cling tightly to the wood, but they apparently do not long survive if their roots are covered up with either Moss or peat. They do not appear to thrive if exposed to the full light, and they require great attention all the year round, as, being plants with very minute pseudo-bulbs, they cannot withstand drought. *C. macroplectron* is a native of New Grenada, and should be grown in the warm end of the Cattleya house.—W. H. G.

NOTES OF THE WEEK.

Primula obconica.—This pretty Japanese *Primrose* is scarcely ever out of bloom; even now it is bearing numbers of mauve-tinted blossoms. In this respect it forms a good companion to the perpetual-blooming *P. floribunda*. In one point, however, it surpasses that kind, and that is fogs, which have lately played great havoc with *P. floribunda* by destroying nearly the whole of its foliage and greatly disfiguring its blooms, have not injured *P. obconica*, though growing under the same conditions.—H. P.

Erica melanthera is one of the prettiest winter Heaths, and of the large number of kinds in flower at Kew, it stands out from all the rest by its distinct appearance. The flowers are very small, like tiny mauve wax bells with black anthers, and each plant bears myriads of these. The habit is neat, for the floriferousness of the plant checks exuberant growth. It lasts a very long time in bloom throughout the winter; in fact, therefore quite worth growing in a general way. The flowers have rather a fetid odour, but this is not observed if not sought for.

Jasminum pubescens.—This beautiful old white *Jasmine* is scarcely less desirable than the new *J. gracillimum*, which it so nearly resembles, that one might easily mistake one for the other. Both have large white and sweetly scented flowers, and the foliage is similar, but *J. gracillimum* has more of a climbing tendency, while *pubescens* may be grown as a dwarf pot bush. Both kinds may be seen flowering side by side in one of the stoves at Kew, and their fragrance perfumes the house. For cutting from at this season both are excellent, though their flowers do not last long in water.

Veitch Memorial prizes.—At a meeting of the trustees held at South Kensington on Tuesday, the 11th inst., it was decided that a £5 prize and medal should be offered for competition at the principal show of each of the following societies: York Gala, Liverpool, Birmingham, Leicester, Oxford, Derby, and the Royal Horticultural, May 24 (*Cypripediums*). Also at the National Dahlia Show, to be held September 2, a prize of £2 10s. and a medal should be offered in each of the following classes: Self show, parti-coloured show, Pompon, decorative, and single. And further, at the National Chrysanthemum Show, to be held in November, a prize of £3 3s. and a medal should be offered for 24 incurved

Chrysanthemums, distinct; a similar prize and medal for 24 Japanese kinds, distinct; also a prize of £2 2s. and a medal for each of the following: 24 reflexed, 24 large-flowered *Anemone*, 24 Japanese or hybrid *Anemone*-flowered, and 24 Pompons, including *Anemone*-flowered. The object of the trustees in the two latter competitions is to make the exhibitions as complete as possible by inducing exhibitors to bring together specimens of all the best sections of *Dahlia* and *Chrysanthemum* in cultivation. The number of prizes offered during the year are therefore—7 special prizes, 5 *Dahlia* prizes, and 6 *Chrysanthemum* prizes, or 18 in all, each prize being accompanied by a medal. These prizes are open to competition amongst amateurs only.

Justicia purpurea.—Some specimens of this in the stove have been for a considerable time, and still are, objects of great beauty, being thickly studded with bright purple blossoms, which, though they do not remain long in perfection, are quickly replaced by others; indeed, under anything like favourable conditions, a regular succession is maintained. It is a plant of the easiest possible culture. In spring cuttings strike root in a very short time, and if treated liberally throughout the summer, form good bushy plants by the autumn. Red spider is the principal insect that attacks this plant, and it can be readily kept down by means of the syringe.—H. P.

Gesnera oblongata.—Those who want a bright winter-flowering stove plant may find in this old plant all that they wish. It is a shrubby plant, with pale green foliage, and bears an abundance of flowers, which, though small compared with those of other *Gesneras*, are of an exquisite colour, the buds being like velvet. The plant allowed to grow naturally has somewhat of a straggling habit, but the knife may keep it in good form, and it may also be trained. It is a capital plant for trailing on a pillar, and in that way it flowers most freely. It is not a very common plant, and especially in nurseries, but the other day we met with it in bloom in the Handsworth Nurseries, near Sheffield, where it is a favourite plant and well grown. Its flowering season extends over two or three months. It is a South American plant, originally discovered by Humboldt and Bonpland in Peru, near the city of Quito.

Omphalodes verna.—The Creeping Forget-me-not, or *Venus' Navel-wort*, as it is still called in old-fashioned English gardens, is as beautiful in every way as our native Forget-me-nots, and far more useful for clothing out-of-the-way places in our gardens. But, however well it may grow in such places, it should be seen, we are told, gathered fresh from, or growing in, its native wilds to be fully appreciated. On San Romola, near San Remo, it is said to outstrip in beauty the alpine Forget-me-not (*Myosotis alpestris*) itself—a fact not difficult to believe, after seeing the sheets of clear blue, white-eyed flowers of this plant growing in a semi-shady spot. *Rhododendron* beds, the shady side of shrubberies, &c., suit it exactly, and in such positions I have never known it to fail. There is also a white variety, but it is not nearly so handsome as the type. Both may be increased to almost any extent by division; the stems as they run emit roots from their undersides, and buds at intervals on the top. These, broken into small pieces, soon make good plants.—K.

Cyrtanthus McKeni.—This is a plant that should be taken in hand by nurserymen, so that it may come into general cultivation, as it is, without doubt, one of the prettiest and most elegant greenhouse plants we have for winter-flowering. It is a South African bulbous plant, the best of a genus containing some fifteen species, a few of which, such as *angustifolius*, *obliquus*, being old garden plants. *C. McKeni* has long Grass-like foliage; its flower-stems are erect, and as thick as a quill, each being topped by a cluster of flowers, usually about five together. The flowers are about 2 inches long, tubular, slightly curved, pure ivory-white, and sweet-scented; a good potful of bulbs will produce about a dozen of these spikes, which when in bloom are very chaste and beautiful, and a plant lasts in bloom for several weeks. It has been in flower in the Heath house at Kew since long before Christmas, and is likely to last a month longer. It is, therefore, a most desirable plant, easily grown in a cool greenhouse, or even a frame,

and may be readily increased. It is to be regretted that such a plant should only be seen in botanical collections, but the public should create a demand for it; then no doubt a supply would come, as in the case of other plants that have been known only in botanic gardens. C. McKeni comes from Port Natal—surely not an out-of-the-way place from which to get bulbs.

Eranthemum pulchellum. Flowers of a rich blue are valued at any season of the year, and in mid-winter they are specially acceptable; we are therefore glad to see this beautiful old-fashioned plant again coming into favour, having received sprays of it from several of our readers, to whom it appears to be a novelty. It is, however, anything but that, having been introduced to this country from India nearly a hundred years ago. It was largely grown some years back, but of late it has fallen into disrepute. It is, however, one of the very prettiest soft-wooded plants at this season of the year, but worthless in a cut state, as its flowers fall so rapidly. They are freely produced, and are of a most lovely shade of blue. Cuttings should be struck every spring and the old plants discarded, as young plants are not only handsomer, but produce the finest flowers.

The late Mr. Moore.—At the meeting of the floral committee at South Kensington on Tuesday last, the chairman, Mr. G. F. Wilson, alluded to the death of Mr. Thomas Moore, who had for so many years been connected with the floral committee of the Royal Horticultural Society. It was proposed by Mr. Hibberd, and seconded by Mr. Fraser, that a letter of condolence be sent to Mrs. Moore. It was also proposed that something should be done by Mr. Moore's many friends to mark the esteem in which he was held. It was agreed that a subscription list be opened, so as to form a fund by which a memorial may be erected over Mr. Moore's grave in Brompton Cemetery. In order that everyone who desires may be enabled to contribute to the fund, each subscription will be limited to a guinea in amount. Mr. Veitch, Royal Exotic Nursery, Chelsea, has undertaken to act as treasurer, and Dr. Masters secretary, of the fund.

Turner Memorial prizes.—The money subscribed twelve months ago as a memorial for the late Mr. Charles Turner, of Slough, amounted to £182 18s. 6d. That amount was invested in Consols, and £20 will be available for prizes every year for a period of ten years. That amount will be given in prizes next season at the following exhibitions: The National Auricula (Southern Section) and Primula Society, at South Kensington, on April 26, 1887, for six show Auriculas (to be competed for by amateurs who do not employ a gardener regularly). The exhibits must contain at least one representative of each of the four classes—green, grey, white, and self-edged. Four prizes—40s., 30s., 20s., 10s. The National Carnation and Picotee Society, to be held at South Kensington, on July 26, 1887. Six distinct Carnations and six distinct Picotees (to be competed for by amateurs who do not employ a gardener regularly). Four prizes—40s., 30s., 20s., 10s. The Newcastle-on-Tyne Botanical and Horticultural Societies' Exhibition, to be held in the Jubilee Grounds, on August 30 and 31, 1887. Twelve distinct Roses: three prizes—50s., 30s., 20s.; twelve distinct Dablias: three prizes—50s., 30s., 20s. (to be competed for by amateurs or gentlemen's gardeners).

Rainfall at Dorchester.—I have just been making up the rainfall at this place for the past year, and I find it to be greatly in excess of the average, being not less than 47.44, or very nearly 47½ inches. I have recorded the rainfall here for the last ten years, and I find the average for that time to be 38.76 inches. The fall of 1886 was nearly 4 inches greater than in any other year in the ten years, 1877, in which there were 43.67 inches, coming nearest to it. December, 1886, was the wettest month during that time, when we had 8.29 inches, October, 1880, in which there were 7.81 inches, coming nearest to it. The new year has set in with a heavy rainfall: the first four days has given us 2.31 inches, which makes just over 10½ inches since the 1st of December, and in

consequence the land is full of water; in fact, the garden here is literally a swamp. In making up the annual amount of rainfall, one cannot help thinking with what a liberal hand Nature does her work. Here we have an average of 38½ inches. This would amount to about 3875 tons, or 868,000 gallons of water to the acre. And this makes me think that fruit trees and other things planted out in houses frequently suffer from an insufficient supply of water. We have a Peach house here which has an area of about 1000 feet. What would Nature's supply be to this area? I find it would be just over 20,000 gallons per annum, but I much doubt if it has been supplied with that quantity.—D. UHILL, *Morilton.*

HARDINESS OF PLANTS.

To what degree the ability of plants to endure our severe winters is affected by culture is shown by the notoriously hardy common Wallflower. Growing out between the crevices of a stone wall, where its root-room is of the most limited description and its food of the scantiest, it endures our hardest winters with impunity, but when grown in a deep rich soil it perishes. We have noteworthy examples of this here. On a rockery, under which there happens to be a good depth of tolerably rich soil, we have planted Wallflowers annually for some years, and they have grown much more robustly than usual, and made, indeed, great bushes with numerous and tall stems, which, when in flower, make very fine objects indeed; but every winter some of the plants perish by frost, or are greatly injured, and in severe winters they are all killed outright. The reason of this is, that the plants push long, tap-like roots down between the rocks into the good soil beneath, and never ripen their growth sufficiently. Plants of the same sowing left in the seed-bed of rather poor, thin soil all survive every winter, and so do plants put out elsewhere under similar conditions. Of course, gardeners are familiar with such facts, I daresay, but they are not weighed as fully and as often as they ought to be. A Peach or a Vine, or any other tender tree or plant, is just affected in the same way, and I believe myself that the root culture under such circumstances has far more to do with success than the training and management of the branches. Whether a plant be weak or strong, if it has to produce flowers, and, above all, fruit, everything depends on the ripening of the wood. The stronger and more vigorous the shoots are, the more fertile they will prove, provided they are matured to the core. Grossness is generally regarded as an indication of barrenness, but the barrenness does not result from the grossness, but from immaturity. Ripen the shoot perfectly, and it will not only bear fruit, but it will bear more than any other. This I believe to be the true philosophy of this matter. It may be wise culture not to grow shoots so strong that they cannot be ripened with the means at command; but that does not affect the principle involved. The grossest of all shoots are produced when the roots are allowed to penetrate deeply into a rich, moist soil, from which they continue to send up moisture into the tops long after the temperature of the air has fallen below the growing and maturing point at the approach of winter; hence the tissues remain soft instead of hardening, and perish under frost or severe cold. Rivers's plan of producing strong and fertile shoots by means of rich top-dressings applied to the surface of his orchard-house trees was the right plan. The roots were near to the surface, and as well fed as if they had been deeper down; but being affected by the external temperature almost as soon as the branches, the action between the branches and the roots was more reciprocal, and strong, but well-ripened buds were the result.

Take the Grape out of doors, again, in England. To digress a little, I think, it must be confessed that its open-air culture has not been a success as yet in the right sense of the word. Many people make much of the fact that vineyards were common in England some centuries back, and infer from that that the Grape was grown success-fully then, and that if it fails now it is because either the culture or the climate has gone wrong. I once thought this myself, but of late the accidental perusal of some references to the subject has given me a different opinion. I believe I am correct in stating that the culture of the Vine in this country did not extend over a long period at the time when vineyards did exist. It just seems to have occurred to our ancestors, as intercourse with the Continent became more frequent, that they might grow Grapes outdoors as well as the French, and, just as gardeners do now, they made a rush to try the new idea, with the result that after a fair trial Vine culture out of doors was given up. This to me appears to be one at least, if not the legitimate inference to be drawn from the practice of our forefathers.

But to return to the subject. Has anyone ever tried to grow the Vine out of doors with its roots on an impervious bottom and in a border 6 inches deep? My impression is, that such a plan would succeed, and that under such conditions early varieties might be ripened in good time if the Vines were carefully trained on walls. What hinders Grape culture in this country is the want of sufficient heat; the fruit does not ripen perfectly; hence anything that could promote early or quick root action and growth would help to get over that difficulty, and conditions under which the roots were kept as warm as the tops in a shallow border well exposed to the sun would do that. At all events the wood would ripen sooner and better than if the roots were 2 feet deep, and the ripening of the fruit depends on the ripening of the wood. Grapes under glass seldom or never colour till the wood begins to get brown. S. W.

Plant names.—To the somewhat familiar question, "What's in a name?" the compositor in a horticultural printing office might perhaps reply that there is a very great deal—an alphabet or two—in some names. At this season they may be observed in full cry, like Calverley's "long-backed fancy mongrel trailing casually" through the spring seed catalogues. As the same author would remark, "the imagination boggles at" them, even at the appellation of such a "grand and greatly improved flower" as *Zinnia elegans robusta grandiflora* double. Here is a chance fragment from my friend Short's gardening diary: "In the library, looking out a few dictionaries, &c., for my mar, who will not spell the Orchid names correctly. Hearing a noise outside, went out, and found my good neighbour Lacon stuck fast in the garden gate with an armful of the new patent telescope garden labels of his own invention. Showed me practically how, like Euclid's parallels, they can be produced ever so far both ways (not) to meet the requirements of modern nomenclature. Brought me the promised plants of *Chrysanthemums*, *Monsieur Juan Cruz de Eguileor* and *Monsieur Edouard Pynaert Van Geert*. Spent half an hour with him in the garden. Much pleased with my arrangement of a clump of *Helianthus multiflorus simplex maximus* in a bed of *Petunia hybrida nana compacta grandiflora*, with background of *Cupressus Lawsoniana erecta viridis argentea variegata*. Gave him seeds of *Hellebores Apotheker Bogren* and *Commerzienrath Benary*. N.B.—Must really remember to ask Lacon not to bring his dog Bob with him in future. The brute got into the Orchid house and knocked down the *Odentoglossum Pescatorei Vervaeianum* and the *Campylobotrys Ghiesbreghtii variegata*, and then went and scratched up nearly all my *Matricaria eximia*

nana aurea crispa, and rolled in a patch of *Heli-chrysum monstrosum nanum atre-sanguineum flore-pleno.*"—G. H. E.

FERNS.

LIP-FERNS, OR CHEILANTHES.

MANY who have a taste for Ferns and possess a small greenhouse for their accommodation have to lament the want of interest which their favourites afford them. This is usually attributable to the kinds selected being too large and monopolising too much room. Small houses should not be filled with large kinds simply because they are easily grown. What is wanted is variety, and there are many elegant small-growing Ferns which thrive admirably in a greenhouse temperature, and which would, if properly cared for, furnish this. Many have an idea that Ferns cannot have too much water, and consequently they are kept constantly drenched both overhead and at the roots. Such treatment in the case of bold, robust-growing kinds may not be detrimental, but it is one of the chief reasons why we see so few choice Ferns thriving in a greenhouse temperature. The majority of the Cheilanthès succeed well under cool treatment. Water should never, however, be sprinkled upon their fronds, and during winter it will be found safest and best to err on the side of drought, both in the atmosphere and at their roots. They should be grown in rather small pots, which must be well drained. The soil best suited for their requirements is a mixture of sandy loam, peat, old mortar rubbish, and small pieces of sandstone, a compost which will keep open and porous, and which will allow water to pass freely away. As just remarked, the fronds should never be wetted, and during winter a dry atmosphere must be maintained, whilst as much light as possible at this season should be admitted, but in summer they should be well shaded from the sun's rays. To obviate shading, green glass is sometimes used, but this is about the worst substitute for ordinary shading material that can be used; not that the Ferns refuse to grow under it (although we are not sure that it suits them as well as clear glass), but because the green glass casts such a ghastly light upon the leaves, quite destroying the effect of the beautiful tints of green which the fronds assume in their different ages and stages of growth. From experience we may safely assert that in the culture of plants in our climate nothing is better than to have the summer shading material of such a character, and adjusted in such a manner, that it may be applied or removed conveniently, as occasion may require. Ferns with pendent fronds should always be allowed to assume their natural habit; to keep such fronds in an erect position not only destroys the graceful appearance of the plants, but eventually destroys their vigour. The following kinds are all beautiful, and all well deserving the attention of Fern lovers requiring choice plants for a cool house, viz:—

C. MYSORENSIS.—An elegant plant, found growing in dry, rocky places in Southern India and Ceylon, also in China and Japan; the form from the latter country is the most hardy and robust, and its stems are densely clothed with dark scales. The fronds are narrowly oblong in outline, and their pinne are divided into small segments.

C. ARGENTEA.—This charming little Fern seldom exceeds 3 inches or 4 inches in height. Its fronds are triangular in outline, borne upon slender polished stems, bright green on the upper side, and silvery white beneath, edged with a line of black soft. It is common in Japan, and is also found in China and Siberia.

C. SZOVITSI.—This is said to be a European Fern, being found, although very sparingly, in Italy and some parts of the south of Austria. It is, however, widely distributed in Asia, and is found at considerable elevations in Northern India. It is not a large-growing plant, its fronds seldom exceeding 7 inches or 8 inches in length, and often less than 2 inches in breadth. They are broadly lance shaped in outline, the segments being twice

or three times divided. The stems and undersides of fronds are densely clothed with white and brown woolly hairs and scales; the upper side is deep green.

C. ALABAMENSIS.—The fronds of this, when well grown, attain a length of from 4 inches to 8 or 9 inches; they are narrowly lanceolate in outline, three times divided, the ultimate segments being small, smooth on both surfaces, and deep green in colour. This very elegant little Fern is tolerably plentiful throughout Georgia, Tennessee, and Alabama.

C. CAPENSIS.—The stems of this are smooth, brown, and polished; fronds bright green, ovate in outline; segments entire, bluntly ovate, the lower segments much the largest. South Africa.

C. SIEBERI.—This is another elegant little species, of tufted habit. Its fronds vary from 3 inches to 6 or even 9 inches in length. They are oblong in shape, and about three times divided into small, oblong-ovate segments, which are somewhat coriaceous in texture, and deep green and smooth on both surfaces.

C. HISPANICA.—This Fern is somewhat sparingly distributed through Spain and Portugal. Its slender stems are of a rich polished brown, springing from a dense tuft of stiff hairs of the same colour, which envelop the crown of the plant. The fronds (under cultivation), including the stems, are about 6 inches long, and over an inch wide, but in the wild plant they are somewhat smaller; they are coriaceous in texture, dark green, and smooth on the upper side, but the reverse side is clothed with long chestnut-coloured hairs.

C. LANGUINOSA attains a length of from 6 inches to 8 inches or more: the fronds are ovate-lanceolate in outline, and slightly under 2 inches in width, firm in texture, bright lively green above, and densely clothed on the underside with long woolly tomentum. It is found in Wisconsin, California, and elsewhere.

C. MULTIFIDA, a fine robust kind from South Africa, has dark shining brown stems and fronds, which are triangular in outline. They attain a height of from 9 inches to 1 foot or more, and are three or four times divided; the segments, which are narrow and oblong, are of a firm texture, smooth, and deep green in colour.

C. FRAGRANS, often called *C. odora*, is another European plant, although not a native of Britain. It is very abundant in Madeira and the Canary Islands; is found somewhat sparingly on the rocks at Gibraltar, in various parts of the south of France, and occasionally in Switzerland. The fronds, which have an agreeable odour, are some 6 inches long, by about an inch in breadth, and twice or thrice divided. They are deep green on the upper side, but pale beneath. Other elegant kinds for a greenhouse are *C. vestita*, from Carolina; *C. tenuifolia*, the Australian form; *C. myriophylla*, from Chili and Peru; and *C. lendigera*, from New Grenada. W. H. G.

INDOOR GARDEN.

NEW RACE OF CHINESE PRIMULAS.

THE Royal Horticultural Society's silver-gilt medal was never more worthily awarded than it was last Tuesday, when it was given to Messrs. Sutton, of Reading, for what was, perhaps, the finest, largest, and most varied collection of new double and single Chinese Primulas ever shown in London. Upwards of four hundred plants were exhibited, every one being a credit to the grower. Notwithstanding the bad weather lately necessitating a good amount of fire heat, the plants were not drawn, but stocky in growth, with luxuriant foliage and dense trusses of bloom. No fewer than sixteen sorts were shown, all raised by the exhibitors, and ten of them had not been shown before. These new sorts show what great strides the Messrs. Sutton have made in the improvement of this flower, the most remarkable kinds being the so-called blues, which, by the way, are not true blues yet,

though these may come. But a few years ago no blue Primula existed; then Messrs. Carter showed their Holborn Blue, a single sort with large flowers of a purplish blue. Now Messrs. Sutton have besides single blues two good double blues, one having Fern-like foliage, the other the ordinary foliage of the Chinese Primrose. The colour of these doubles is even brighter and a nearer approach to true blue than that of the singles, which are really beautiful sorts. The floral committee had no hesitation in certifying these double blues, and, no doubt, they were a surprise to many. One member of the committee, Mr. George Maw, made a suggestion as to the possibility of intercrossing a white Chinese Primula with a yellow-flowered species, as he thought that a yellow winter-flowering Primula would be valuable. Whether such a cross as this is possible or not no one can say, but all must admit that the attempt is worth making, and, seeing the rapid steps that are being taken in perfecting the blues, why need we despair of yet seeing yellows? Other remarkable doubles in the Reading collection were those named Double Scarlet, which is not, however, a real scarlet, but a brilliant carmine; Double Rose, an exquisitely beautiful sort of a colour pleasing to everyone. These doubles form quite a different race from those raised by Mr. Gilbert, of Burghley, and sent out by Messrs. Osborn, of Fulham. These Burghley doubles have fuller flowers—more rosetted, so to speak, but they have not the brilliancy of colour of the Reading doubles; and, further, they are far more delicate in constitution and more difficult to grow and propagate. But there is no need to disparage the Burghley hybrids in order to extol the Reading race; both are invaluable, and it is well that they are different; and let us hope that Messrs. Sutton and other raisers will still persevere in the improvement of the doubles and try as much as possible to originate new colours, for that is what is most wanted now. We have a surfeit of crimsons, roses, and whites among Primulas, but blue is a decided departure from the old track, and yellow is still within the range of possibility without even intercrossing with another species; for, be it remembered, Messrs. Huber, an Italian firm, showed in London some remarkable single Chinese Primulas having the yellow centres abnormally developed, almost obliterating, in fact, the white, and therefore a true yellow sort may be seen shortly, for that is, we believe, the ultimate aim of Messrs. Huber. As to Messrs. Sutton's single sorts shown, they do not call for special comment, as similar, if not identical, sorts have been shown numbers of times in London of late years, though no doubt the committee were just in certifying them. Among the single sorts, however, there were some remarkable for curious leaf development; two have foliage like Curled Kale or Parsley, but these seemed to lack quality of flower. To combine this handsome foliage with good flower-trusses and varied colours will, no doubt, be an object for attainment at Reading. Another point about the doubles that must not be overlooked, as it is so important, is, that the sorts may be perpetuated from seed; in fact, the grower of the Reading collection assured us that there was not a "rogue" in the batch of the double scarlet. This is a great gain, as the drawback to other doubles is the difficulty attending their propagation.

Forcing *Choisya ternata.*—I saw it recently stated in *Gardening Illustrated* that the Mexican Orange flower, as this shrub is called, is a good plant for forcing into bloom early, but as I have never seen or heard of its being forced, would any reader enlighten me as to its treatment as a forced shrub? It would be a great gain to have a good supply of bloom of this lovely white sweet-scented shrub at Christmas, or at any time during winter.—W.

THE BRUGMANSIAS.

FIFTY years ago Brugmansias were amongst the most popular of greenhouse plants. They were grown in almost every good garden in which there was a greenhouse or conservatory big enough to accommodate them, and the records of the Royal Horticultural Society tell us how popular they were at flower shows notwithstanding the fact that they are not very suitable for pot culture. Somehow or other, however, Brugmansias have been elbowed out of general cultivation; like a good many other old-fashioned plants, they have given place to more modern, if not more beautiful, introductions. Some good specimens of them may have been seen at Kew, and also at Chiswick in old times.

The Brugmansias should be strictly called *Daturas*, for botanists tell us that there is no material difference between the two genera; in a gardening sense there is, however, a difference, and an important one; therefore we cannot do better than retain the good old garden name of Brugmansia. Brugmansias are all shrubby plants, while *Daturas* are mostly, if not all, annual. A good many names are given under the head Brugmansia in books and catalogues, but there are really only three distinct plants that should bear that name, and two of these are a puzzle to many, who fail to see the difference between them. The three species are *B. arborea*, a native of Peru; *B. suaveolens*, said to inhabit Mexico chiefly; and *B. sanguinea*, also from Peru. The names *B. candida*, *B. Gardneri*, *B. cornigera*, *Knightsi*, *bicolor*, *frutescens*, and others are all synonymous with one or other of the three species above-named. The two white-flowered kinds, *B. suaveolens* and *arborea*, are so variable, and found in such widely separated regions, that it is no wonder the different forms of them have received specific names, and these have been transmitted to and perpetuated in gardens.

B. ARBOREA is a very old plant, and was known to Linnaeus, who named it. It is the Floripondio of the Spaniards of South America, who grow it in their gardens and much prize it on account of its noble white flowers. In a wild state it is a large shrub or small tree, growing from 15 feet to 20 feet high. It inhabits a wide region in the north-west parts of South America, but it is also found in Brazil. It flourishes on the table-lands of the Andes up to 9500 feet elevation, where the mean temperature is 50°, but it luxuriates most in the valleys by the sides of watercourses. Orchid collectors in Bogota and other districts speak of its being a striking plant everywhere, and say, moreover, that there are yellow and rosy pink-flowered varieties of it to be seen, besides a double-flowered

sort, which is called the Double Floripondio. This double kind is a wild plant, and must be the same as that we have in gardens under the name of *B. Knightsi*, which is perhaps the commonest of the three Brugmansias in gardens; it is sturdier in growth, and is frequently planted out during summer in the London parks. *B. arborea*, in greenhouses, grows from 10 feet to 15 feet high, has broad leaves, often coarsely toothed, and produces noble white trumpet-shaped flowers, from 7 inches to 9 inches in length and pure white. The difference between *arborea* and *suaveolens* seems to be as follows: In *arborea* the flowers have long, attenuated tails to the corolla lobes, whereas in *suaveolens* there

perature is just suited to them. *Datura candida* is the same as *B. arborea*, and so is *Datura cornigera*, a native of the Organ Mountains, figured in the *Botanical Magazine* many years ago.

B. SANGUINEA, the third species, commonly known by its synonym, *B. bicolor*, is very different from the others, but it is also of tree-like growth, varying in stature from 5 feet to 20 feet. It is a native of Peru, where it is known by the name of Red Floripondio, or *Campanilla encarnado*. There is no need to describe here how it differs technically from the white-flowered species, as it may be known at once by the colour of its flowers, which are funnel-shaped, and measure from 7 inches to 9 inches in length. The usual colour is a bright orange-scarlet, lessening in intensity in the tube, until it merges into orange-yellow, and then blends with the green at the base. There is a variety of it, called *flava*, which has its flowers wholly yellow, but this form is rare. The flowers of *B. sanguinea* are produced singly from the tips of the branches, so that by judicious pruning, flowering spurs can be greatly increased. *B. sanguinea* was first introduced to this country by a Mr. Crawley, who brought seeds of it home with him from Guayaquil, in 1833, and since that time it has been more or less popular in gardens. As it grows wild in the mountainous parts of Peru, it is half-hardy, and may be grown in perfection in a cool greenhouse, and even planted out in summer; indeed, the first plant which flowered in this country (which was at Hayes Place, Kent) had withstood the winter of 1833 out of doors.

B. SUAVEOLENS is, next to *Knightsi*, the commonest Brugmansia in gardens, and there are few nobler ornaments to a greenhouse than a large and profusely flowered specimen of it. It is a most abundant flowerer, and the fragrance emitted by a large bush of it is almost overpowering. The

Brugmansia arborea in the conservatory at Lews Castle, Stornoway, N.B. Engraved for THE GARDEN from a photograph.

flowers, which are larger than those of *arborea* and pure white, often measure over 1 ft. in length, and are more bell-shaped than those of *B. arborea*. It is also less tree-like in growth than *B. arborea*, though, in a wild state, it reaches 15 feet in height. It is said to be a native of Mexico, while *B. arborea* is confined to South America. If this be so, it affords additional evidence that the two plants are specifically distinct. It was introduced to Europe so long ago as 1733, and has been grown in English gardens for upwards of a century. The Brugmansia known as *B. Gardneri* is the same as *B. suaveolens*. Among other so-called Brugmansias there was a very beautiful one introduced

is scarcely any lengthening of the segments. In some of the specimens in the Kew herbarium the corolla lobes of *arborea* are 2 inches long. This and other characteristics, not so important to a gardener, are sufficient to distinguish it from *suaveolens*. The flowers are not so sweet-scented as those of *suaveolens*, but are fragrant in the evening. This is the Brugmansia that is said to have become naturalised in parts of California, particularly about San Francisco, where it is much used for room and table decoration. In fact, in all tropical and sub-tropical gardens, Brugmansias are favourite plants; they form a great feature in gardens in the Canary Islands, South Europe, and other places where the tem-

about fifty years ago, and figured in Paxton's *Botanical Magazine*, under the name of *B. Waymanniana*. The flower is represented as being double, or rather a sort of hose-in-hose. The colour is purple and white, and if as beautiful as the plate shows it to be, it must be a most desirable plant. Does anyone know if it now exists in gardens? I could find no trace of it among the herbarium specimens at Kew, but from the description given it seems to be a shrubby plant; hence a *Brugmansia*. Another beautiful plant, once called *B. floribunda*, is now placed in the genus *Juanaltoa*, and is *J. aurantiaca*, which, I believe, is in cultivation.

CULTURE.—One mode of treatment applies to all three *Brugmansias*, as they are of about the same degree of hardiness, and much the same in style of growth. They are not well suited for pot culture unless the pots or tubs in which they are placed are very large, on account of the roots being so bulky and spreading so widely. It is best to plant *Brugmansias* out permanently in a conservatory or greenhouse border, where they can have room to fully develop themselves. They should have at least 15 feet head-room space; hence it is only in good-sized houses that *Brugmansias* can be grown to perfection. The illustration here given is that of *B. arborea* in a Scotch garden, and it shows well what a noble plant the white *Brugmansia* is in a conservatory. Mr. Comings, the gardener at Lews Castle, who sent the photograph, states that the plant in question bears hundreds of flowers every season, and is the chief feature of the garden during August and September. He says, "It gives no trouble when once well planted (it should not be kept in pots), its only requirements being an occasional pruning in order to keep the wide-spreading branches within bounds. No flower," he says, "in my estimation can equal this white *Brugmansia* for purity and fragrance, and for room or church decoration it is unequalled, as, if gathered before the blooms are quite expanded, they last a long time in perfection." The position in the greenhouse in which a *Brugmansia* is planted should be well considered, and the soil for it must be good, such as turfy loam and rotten manure, so as to induce vigorous growth. A hole should be taken out a yard deep and as much across, and a good layer of drainage material put at the bottom. A young, healthy plant will soon shoot up to its full size, after which it may be kept within bounds by close pruning, which is best done in autumn; after that the plant must be kept drier throughout the winter. Subsequent top-dressings or applications of liquid manure will always remedy exhaustion from profuse flowering. Old plants, particularly those regularly pruned, are most floriferous.

Open-air culture used to be much practised here and is now on the Continent, and some of the finest effects in August and September are produced by means of *Brugmansias*. Open-air culture, however, requires more attention than greenhouse treatment. The plants must be grown in pots in order to be wintered well. One plan, and that generally followed, is to plunge three-year-old plants in pots in good rich soil in May, well water them throughout the summer, and in August they will flower abundantly. In October they may be lifted and placed in a greenhouse, or, failing this accommodation, set in a dry cellar, or any dry place out of reach of frost. But by this plan the roots run over the tops of the pots, so that the plants cannot be watered well in winter, so a better way is to enlarge the hole at the bottom of the pot through which the bulk of the new roots will descend, and at lifting time there can be cut off close to the bottom of the pot. Still another plan is to

turn the plants out of the pots at planting time, and then about the end of July cut with a spade round the balls close to the plant, working in at the same time some short stable manure, in which the new roots will run and form a dense mass, which will enable the plant to withstand lifting in autumn and repotting without injury. One of the old growers used to always follow this plan, and in one season extending over six weeks he had no fewer than a thousand flowers on a four-year-old plant 6 feet high and 10 feet through. *Brugmansias* out of doors associate well with noble-leaved sub-tropical plants, even if they do not flower. When grown in large pots or tubs, the best time to replenish the soil is in early spring just when starting into growth. They are all readily increased by cuttings made of the half-ripened shoots. W. G.

Cyclamens planted out.—Having found so many greenhouse plants to succeed so much better when planted out in summer than when kept in pots the whole year round, I last year resolved to try Persian *Cyclamens* in the same way in which we treat *Callas*, *Eupatoriums*, and a host of other things, viz., planted out in the open ground in May. We selected a border close to a wall, and having dug it up deeply and given it a good dressing of manure, the *Cyclamens* were planted out about 1 foot apart each way; and, beyond keeping them free from weeds, they received no attention whatever until September. They then had produced fine heads of young foliage, and many were showing flower. They were therefore carefully lifted with good balls of earth, and the way in which the roots clung to the manure and their healthy, vigorous look proved that they liked a good rich diet, and plenty of it. They certainly were altogether more satisfactory than if they had been kept in pots. When planted out they do not get so dust-dry as when in pots, and they are in a more equable condition both as regards moisture and temperature. They, therefore, enjoy their rest, and start afresh with renewed vigour. I am sure many will find that the plan of planting out a good deal of the stock that is usually kept in pots is a great gain; by it not only are better plants secured, but labour is economised. —J. G. H.

The red and white Lapagerias.—There are two fine plants of *Lapageria*, one red and one white, growing in the large conservatory at Lillesden, Hawkhurst, Kent. *L. rosea* is planted out in a narrow border against the back wall of the house, and *L. alba* is growing in a large slate tub. Both are in robust health and still bear a few blooms, but of the two the white variety certainly appears to be the more vigorous. Many of the shoots are extra strong, some being fully 8 yards long. They receive a dressing of rough peaty compost in spring. There are some positions in which they would do best planted out, but if a large pot, wooden or slate tub can be set in a cool situation they are capable of supporting very fine plants. At Lillesden the border is filled entirely with compost suited to the *Lapageria*, a matter very different from merely filling an excavated hole with specially prepared soil. That plan was many years ago, to my knowledge, tried in the Lillesden conservatory, and, like many other similar attempts, ended badly. Whether planted in pots, tubs, or borders, *Lapagerias* require a rough porous compost such as was described in THE GARDEN (p. 37), and abundance of drainage so arranged as not to easily get clogged. *Lapagerias*, too, require large quantities of water, especially during hot sunny weather, but if this does not pass freely away the soil becomes sour, and therefore poisonous to the roots. The plant of the white variety last autumn perfected a large quantity of seed, and some of this sown in heat as soon as gathered germinated in about six weeks. When I saw the seedlings recently they were about 3 inches high and looking healthy. The greatest difficulty usually experienced with young layered *Lapagerias*

is in effecting a good start, and if they could be more generally raised from seed useful sized plants might be formed much more quickly.—W. I.

SWEET-SCENTED FLOWERS.

AMONG plants with scented flowers that at this season of the year perfect their blooms in the temperature of an ordinary greenhouse, the first place must be assigned to the two forms of the evergreen *Daphne indica*, which are now about at their best, and whose perfume is so pronounced that it scents the whole house in which the plants are growing. The form most commonly grown is the deep coloured one, which is in all respects a more satisfactory subject to deal with than the white-flowered kind. It grows more freely and its foliage is of a deeper green, so that even when out of bloom it is more attractive than the pale sort. Still, the little clusters of pure white blossoms on the latter are so beautiful, and afford such a pleasing contrast to those of the typical form, that both are well worth a place in every garden in which accommodation for them exists. Though by no means particular as regards cultural requirements, they are frequently met with in anything but a satisfactory state. Owing to their not succeeding well on their own roots, many cultivators graft them on the Spurge Laurel, and with good results; while in the hands of some they are equally satisfactory when raised from cuttings. For cuttings, select shoots in rather more than a half-ripened condition, that is to say, a little before they acquire a woody texture, and having removed the bottom leaves, insert them in well-drained pots filled with sandy compost and pressed down firmly. About 4 inches is a good length for the cuttings, and they often root better when inserted around the sides of pots than when placed singly in small pots; contact with the sides seems to hasten the formation of roots. If kept close either in a propagating case or under a bell-glass in a structure warmer than that in which they have been growing, roots are soon produced, and when sufficiently established they may be potted off. A mixture of open turfy loam, well decayed leaf-mould, and a liberal amount of sand is a very suitable compost for this *Daphne*.

Grafting may be performed either on plants well established in small pots or on pieces dug up for the purpose, and potted after the operation is carried out. The first method is, however, to be preferred; all that is necessary to ensure success is to select good shoots in the same condition as for cuttings, and graft them in the wedge or side manner as near the ground as possible; after that they must be kept close till a union has taken place. They will only then require shifting into larger pots when necessary, but in either case their progress is more rapid if kept in a structure warmer than an ordinary greenhouse during their earlier stages. Care must be taken that the pots are not too large, as even if full of roots a little stimulant during the growing season will suffice to keep them in health. Soot water is one of the best of stimulants, as it imparts depth of colour, and may be liberally applied during summer. This *Daphne* is, however, seen in its best state when planted out. Its rate of growth is then much more rapid than in pots, and where it is expected to supply flowers in a cut state this is a great consideration, as the removal of a few flowering twigs can be effected without disfiguring the plant. It is quite at home on a conservatory wall, but before planting care must be taken that the bed for its reception is thoroughly well drained, and that the compost employed is not of too adhesive a character.

Another sweet-scented subject now in bloom is *Jasminum grandiflorum*. It forms a regular growing twigg bush, with deep tinted evergreen foliage, much like that of the common *Jasmine*, and each shoot is terminated by a number of pure white, fragrant blossoms. The common *Jasmine* is such a popular plant, that *grandiflorum* is sure to be appreciated, especially in midwinter. It strikes root readily if half-ripened shoots are

taken during summer and treated as just recommended in the case of the *Daphnes*. *Luculia gratissima*, another winter bloomer, is a grand object when studded with its large Hydrangea-like heads of pink blossoms, which are, moreover, deliciously fragrant. Somehow or other it has acquired the reputation of being difficult to increase by means of cuttings, but I have never found such to be the case. The cuttings should be formed of the young shoots when they are about half matured, and being dibbled firmly in a light sandy compost, they must then be plunged in a gentle bottom heat in a cool part of the stove. It will be necessary to cover them with a propagating case in order to exclude air; indeed, I know of no other plant that is so irreparably injured as this is if allowed to flag, and this, I think, explains the reason why it has acquired the reputation of being difficult to deal with.

H. P.

SEASONABLE WORK IN PLANT HOUSES.

T. BAINES.

STOVE.—Preparation should at once be made for potting most of the stock in this department. Loam, peat, and sand should, if not already got under cover, be brought in where it will get sufficiently dry for use, for it is scarcely necessary to say that when plants are potted in material that is over-moist, the roots never take kindly to it. The floor of a dry, open shed, where the air will have full play upon the various soils, is the best place, spreading them out thinly, and turning them over a time or two. All empty pots should be thoroughly washed, crocks broken, sticks made and painted, and training wires prepared, before potting operations are commenced, in which case the work goes on more smoothly, and can be got through quicker.

POINSETTIAS.—During the time that intervenes between the *Chrysanthemums* being over and the earliest of the spring-blooming plants coming in there is the most difficulty in keeping up the supply of flowers. This is especially felt where large quantities are required for cutting. Where a sufficient number of *Poinsettias* has been grown to admit of some being kept back in a temperature no higher than would keep them in a healthy condition without pushing on the development of their showy bracts, these may now be placed in the stove, where the heads will quickly expand, and be found very useful through the coming month. Where the plants have been retarded in this way, the bracts do not attain so large a size as when they have been subjected to more heat through the later months of the year, but they will generally be found more serviceable for cut purposes, at the same time being more enduring than when pushed on earlier.

EUPHORBIA JACQUINEFLORA.—Where plants of this have been well grown and are strong, they will yield a second, and in some cases a third, crop of flowers after the sprays produced on the leading shoots have been removed. This, one of the best of all plants for giving a long succession of bloom in winter, is found by many growers difficult to deal with, both as regards its propagation and after growth, yet it is easily managed, provided a little attention is given to its requirements. Like all other spare-rooted subjects, it cannot bear large pots; such as are 6 inches or 7 inches in diameter are large enough for the biggest plants that it is possible to grow in a single season. Care must also be taken that it is never over-watered, especially when the temperature of the house in which it is located in winter is lower than that required by the warmest section of stove plants; and under the most favourable conditions the water-pot must be used with caution during the next two months. Manure-water given now will much assist the production of successional flowers, keeping the heads of the plants as close to the roof as can be done without their touching the glass.

BEGONIAS.—So continuous is the habit of blooming of the best of the winter kinds, that where the plants are strong, they keep on giving an uninter-

rupted succession of flowers. Soft-wooded plants that bloom from the successional growth that is made through the winter in the way common to the section of *Begonias* in question are much influenced in the enduring character of their flowers when cut by the conditions under which the growth that produces them is made. When the plants are stood in light houses or pits, with their heads close to the glass, the growth possesses the requisite substance to enable it to yield flowers that will keep fresh for a much longer time than when the growth is made under the adverse condition of insufficient light. Those who have to provide a constant supply of cut blooms during winter will find that by paying due attention to the conditions that will ensure enduring properties in the flowers, fewer will suffice.

AZALEAS.—Amongst the endless varieties of *Azaleas* that have appeared within the memory of the present generation of gardeners there are few, if any, equal for winter forcing to the old white, and the slightly different *Fielder's white*, especially where the flowers are required for cutting. The robust constitution of the two varieties named, and the free growth that when well treated they make, admit of the flowers being cut with long portions of shoot attached to them, which is obviously a matter of the first importance when they are required for filling vases or stands where flowers with short stems are of little use. One of the best properties possessed by these old varieties is that where needed every shoot that bears flowers may be cut without its having any weakening influence on the plants that will interfere with the succeeding year's growth provided that the roots receive the requisite manurial sustenance during the time the growth is being made. Where a sufficient stock of the sorts under notice exists so that they can be brought into bloom in succession, the supply of flowers may be kept up from November to May. To give a succession, one or more plants, according to their size, should be placed in moderate warmth—the temperature of an intermediate house is better than stove heat—every three weeks. Before moving them into warmth it is necessary to see that they are quite free from thrips, the pest which *Azalea* growers to be successful need to wage incessant war against, as however clean the plants may be early in spring, the chances are that they will be affected with the insect before summer is over. Fumigation with tobacco, or some other of its preparations, will kill the mature insects, but not the eggs, that lie securely sealed up under the little black varnish-like specks that will be found on the leaves; there is nothing that combines the destruction of the insects and the eggs with an absence of injury to the plants like strong tobacco water, to which should be added Gishurst compound at the rate of about an ounce to a gallon of the liquid. In this small plants should be dipped; larger specimens require syringing, laying them down during the operation and allowing them to remain in this position until the solution—which must not be washed off—is dry; it is better not to allow it to find its way into the soil further than can be avoided on account of the sulphur contained in the Gishurst, as it is highly injurious to the roots. Where high cultivation with *Azaleas* is aimed at, the whole stock should now be washed or dipped in this way in the case of plants that have been much affected with the insect, repeating the operation in two or three weeks. At no time of the year can this work be so effectually done as in the winter before the young new shoots are in motion, as then the insects are not only more easily destroyed, but the wash may be used in a stronger state than the plants would bear during their season of active growth.

SHRUBS FOR FORCING.—Such things as *Azalea mollis*, and the Ghent varieties of *Azalea*, *Rhododendrons*, *Andromeda floribunda*, *Deutzias*, *Viburnums*, and *Choisya ternata* should be placed in heat. For these, again, a house or pit, where there is an intermediate temperature of, say, 55° in the night, with a rise by day proportionate to

the weather temperature, is preferable to giving them more heat. When the flowers are brought on in much heat their duration on the plants is shorter than where the progress has been slower. When the flowers are required for cutting to stand in rooms where the atmosphere is dry, and the temperature much lower than that of the structure where they have been brought from, they do not last long; in addition to this they often flag to an extent that detracts from their appearance. The merits of the last of the shrubs named when forced are not yet so generally understood as they deserve to be, but when better known this plant is likely to be in much request.

GREENHOUSE.—The use of fire-heat, more or less rendered necessary by the frosts that have occurred, combined with dense fogs, will have caused the flower-buds of *Camellias* to droop more or less according to the condition of the plants and the care that has been exercised in not allowing the atmosphere to get too dry, and in not using more heat than was requisite. Well known as this fine evergreen shrub is, with its cultural requirements supposed to be equally well understood, there are yet few mishaps more common than to see the flower-buds fall in quantity through the incautious application of fire-heat. The favourite old double white variety is one of the first to suffer in this way; it, and others that have a like tendency to cast their buds, should not be subjected to more heat in winter than that of a warm greenhouse, say 40°, or a few degrees more in the night, and this accompanied by sufficient moisture in the atmosphere and no deficiency of water to the roots. In all cases where it becomes necessary to push the fires to an extent that makes the pipes hot the plants should be stood as far away from them as they can be got. It is needless to say this applies to such as are in pots and tubs and are movable. In houses where the *Camellias* are planted out they usually occupy a central position, and on that account are at a safe distance from the heating medium. *Camellias* suffer less than most things from the presence of insects; yet the pest by which they are most affected—scale—if allowed to get numerous, injures the plants both in health and appearance. An effort should be made at this season to go over the whole stock and give it a thorough cleaning. If the work is carefully done much subsequent labour will be saved, and that at a time when there is less opportunity than at present.

GENERAL HARD WOODED PLANTS.—Fire-heat should be employed with care, not using more, even during severe weather, than will keep the stock well out of danger. This is particularly needful during protracted frost, as any excitement into growth at this early period would, in the case of most things, be highly injurious in its effects.

Late-flowering Chrysanthemums.—Within the last few years attention has been bestowed on late-flowering *Chrysanthemums*—that is, on those whose blooms may be had in perfection at Christmas, or even later, though soon after the commencement of the new year they seem to lose most of their freshness. A good deal doubtless depends upon culture, yet some varieties are better suited than others for late flowering, and among the best are the following, viz., *Grandiflorum*, yellow; *Ethel*, white; *Mademoiselle Lacroix*, white; *Meg Merrilies*, white; *Gloriosum*, pale lemon; and *Source d'Or*, deep orange. All these are Japanese kinds; though there is no end to so-called varieties now in cultivation, yet few bright-coloured sorts are available for late blooming; they lose both colour and freshness. The most satisfactory with us this season have been *Incomparable*, brownish crimson; *Souvenir d'Amsterdam*, crimson and gold; *M. Comte*, purple; and *Père Delaux*, velvety brown. In the *Anemone* section, *Virginal* and *Lady Margaret*, both white, are the best; while of incurved flowers, by far the latest is *Princess Teck*, a fine pure white variety. Of this a yellow sport has been exhibited, and it should be a very useful kind.

A promising sort for late blooming is a Japanese variety sent out last year by M. DeLaux and called M.M. Thibaut et Keteleer. It is short and sturdy in habit; the colour of the blooms is of an intense bright crimson, and they do not seem to become pale, as most kinds do, towards the end of the season.—T.

PAMPAS GRASS, BAMBOOS, AND THORNS.

PAMPAS GRASS FOR COVERT.—Where a good stock of the Pampas Grass is on hand and no particular demand for it, I would strongly advocate its use as underwood, affording, as it does, a great amount of shelter as well as being warm and dry. For the margins of woodland lakes and streams it is of particular value, seeming to delight in such situations, provided it is not too much hemmed in and overshadowed by trees. From a little experiment made here, we find that game in general are very partial to the Pampas Grass, affording, as it does, a cosy retreat and resting ground. A good stock of this plant is easily enough procured by dividing large established clumps and planting these out in a kindly soil in the nursery for a couple of years before transferring them to their permanent positions. In dividing large plants it is best to lift these out of the ground, shake away the soil, and cut them up into pieces of, say, half-a-dozen stems each. By so doing, the risk of cutting and maiming the divisions is much lessened, and the plants grow away rapidly and soon form well established masses. When planting out permanently the Pampas Grass need not be placed closer than 6 feet from plant to plant, for it soon increases in size, and the overhanging leaves quite fill up the intervening space. Any good soil suits the Pampas Grass, but that in which it grows most rapidly is, I have noticed, a dampish brown loam that is not apt to get dried up in summer or to retain excessive moisture during winter. A few clumps of from a dozen to forty plants in each placed here and there along the outskirts of woods and plantations have a most imposing appearance, and all the more so if backed up with dark foliaged shrubs or Firs. The New Zealand Flax and Royal Fern may be advantageously placed in similar situations, and when thoroughly established are both useful and effective.

HARDY BAMBOOS.—The present appearance of a truly grand specimen of *Bambusa Metake* in our home nursery tempts me to say a word or two in its favour as an ornamental and otherwise desirable plant. Not every one of the full half-a-dozen Bamboos offered in our hardy plant lists can be recommended as proof against the shocks of an ordinary English winter; but the one in question may be relied upon as being perfectly satisfactory in this way; here, at least, it has stood quite unprotected for nearly a score of years. I cut one of the wands the other day, just to get a truthful idea of the height of this plant, and it measured 13 feet and 1 inch, was as pliable as a hazel rod, and could be bent so as to make base and tip meet in a circle. The roots wander slowly about, sending up every here and there tufts of wands, so that a single plant placed in an ordinary border soon fills it up. Such a plant as that above described would have a truly imposing effect if well placed in an open recess of the shrubbery and contiguous to a sheet of water. In its present position it is, although in a perfectly open position, saved from cold, cutting winds by a high wall on one side and a big Portugal Laurel on the other. The aspect is eastern, and the soil loam of a not very kindly nature, but evidently well fitted for growing *Bambusa Metake* and the American *Oncoclea* (*O. sensibilis*), this latter uniting, or rather mingling, in a by no means unornamental fashion its Elk's-horn-like fronds with the graceful spikes of the Bamboo. Another perfectly hardy Bamboo will be found in *B. falcata*, a far more refined plant than *Metake*, and quite fitted for taking its place in the alpine garden, where but a few days ago I was admiring it growing

freely, and offering a slight shade to the under-growing Irish Heaths, *Andromeda polifolia*, and that lovely, but rarely seen, *Iris* (*I. gigantea*). It is readily increased by division of the roots.

THORNS IN THE PARK.—In the formation of parks and other grounds it is usual to retain a few of the largest and finest hedge Thorns as standards, and these, if carefully grouped in suitable positions, soon assume a very pleasing and picturesque appearance. That the Thorn, if carefully handled, transplants well when of large size is beyond doubt, as some of our largest country parks have been thus ornamented when the plants were from 12 feet to 15 feet in height. Clump-planting is to be recommended in the case of the Thorn, the best way being to place it in threes or fives, and at a distance of, say, 18 feet apart. There are several advantages accruing from this method of planting, and not the least of these is, that a single fence—for Thorns must be protected from cattle and horses—will serve instead of a number, not to speak of the substantial appearance presented by well-laid-out clumps over single specimens. For the sake of contrast it is to be recommended that a few clumps of the pink, scarlet, or crimson-flowered forms be indiscriminately mixed with the normal white-flowered plant, but by all means keep the colours separate, for a conglomerate mass of white, pink, and scarlet flowers is anything but desirable. In order to relieve the sameness or monotony caused by planting in clumps, it is always advisable to have a few single specimens planted here and there over the grounds. Transplanting the Thorn should always be engaged in in autumn or during mild, open winter weather, for as this is one of our first plants to break into leaf, early planting is therefore enforced upon us, and we cannot far err by taking Nature as our guide. The holes for the reception of the Thorns should be large and wide, and made up of extra rich soil, a cartload of well-decomposed farmyard manure acting wonders when inter-mixed with the ordinary loam. All will be benefited if the pits have been opened for some time previous to that when planting taking place.

RHODODENDRON CULTURE.—Many, indeed the majority of persons, are under the impression that in order to grow the *Rhododendron* in anything like a satisfactory manner it must be planted in peat. Nothing could, however, be further from the truth, as the common *Rhododendron ponticum*, and, indeed, all its varieties, thrive well in soil of very opposite qualities—loam, vegetable refuse, rough stony soil, and even clay if but a little trouble is gone to in improving it. The finest bank of hybrid *Rhododendrons* with which I am acquainted is not a dozen miles from where I write, the soil in this particular locality being a free, sandy loam, with a small admixture of decayed vegetable refuse atop, the whole resting at irregular depths of from 12 inches to about 40 inches on shale rock. During the flowering season it is a treat to see this bank, the gently undulating, irregularly-surfaced ground showing off in a peculiarly effective manner the various and rich tints of the flowers in this almost unique collection. In such a soil, and without coddling of any kind, the rare and beautiful *R. Thomsoni* and *R. Ingrami*, *Lady Eleanor Cathcart*, *Mont Blanc*, and that, to me, finest of all, *Mrs. John Waterer*, thrive luxuriantly. With the greatest of success we have planted *Rhododendrons* of all kinds, commonly cultivated in ordinary woodland soil and without preparation of any kind beyond digging good wide holes and collecting with the spade such leaf-mould as was lying within reach of the pits and mixing it with the soil that was placed in contact with the roots. Dampish ground, but not where stagnant water abounds, is preferred by most *Rhododendrons*, although from this it must not be inferred that the plant in question will only thrive under such conditions, for in some of the woods under my charge it succeeds well in very dry rocky soils and at considerable elevations above sea level. Open, sunny portions of the woodland should alone be

chosen in which to plant the *Rhododendron*, at least if it is intended to flower well.

A. D. WEBSTER.

ROSE GARDEN.

THE "Rosarian's Year-book" for 1887* contains papers on "The Orange Fungus of the Rose," from Messrs. Worthington Smith (illustrated), Fish, Burrell, Grant, and the Rev. J. A. Williams; "The Best Show Roses," by Mr. B. R. Cant; "Single Roses," by Mr. Girdlestone; "Roses in New Zealand," by Mr. Robert Trigg; "Eight Years' Experience of Rose-growing in the Perthshire Highlands," by Mr. A. Hill Gray; and "The Rose Weather of 1886," by Mr. E. Mawley. Mr. Burrell writes as follows concerning

THE ORANGE FUNGUS.

Of the enemies attacking the Rose, that known as Orange fungus, or red rust, is, of all others, perhaps the one which most baffles the skill of the cultivator to find a remedy, easy and practicable of application, and effectual in its results. Like ordinary mildew, it rarely attacks the plants until after the first blooming is past, then, if the weather is at all favourable to fungoid growths, the lower leaves suddenly become affected with a red rust-like powder, the fungus spreading upwards, and in bad attacks to such an extent as to cause the leaves to shrivel up and drop off, seriously impairing the second or autumn blooming of the plants. This fungus is much worse in some seasons than in others. In some of the very wet summers of a few years ago, when my experience of Rose-growing was confined to the north of England, and with almost constant moisture in the atmosphere, I have known remarkable instances in which not a trace of this fungus nor ordinary mildew ever made their appearance during the whole growing seasons of these years; whilst, on the other hand, in seasons after a short fit of exceptionally hot and dry weather the plants suddenly became affected with rust and mildew, the smooth-wooded varieties of the Victor Verdier race, and the very dark, thickly-spined varieties, like *Prince Camille de Roban*, showing the earliest and worst signs of the fungus. Different soils, also, appear to have certain influences in the spread of this fungus. Possibly in no season has it been so rife as in the past one. Yet I have seen remarkable instances of Roses growing in old beds which had not been disturbed for years, and where the soil was light and rich in vegetable matter, where scarcely a trace of the fungus was to be seen, and these, too, of such varieties as *General Jacqueminot*, which are among the worst to become infected with this fungus; whilst, at a short distance to these, in strong, rich, highly cultivated yellow loam, considered to essential to the production of exhibition blooms, and where every attention was paid to high cultivation, the plants were most infested. Indeed, I have invariably noticed on light soils, abounding in vegetable matter, that although the attack of ordinary mildew is quite as bad on these soils as on those of a closer and more calcareous nature, that the plants on the former rarely show signs of any serious attack of Orange fungus compared with those on the latter. Whether or not this is owing to the winter rains carrying the resting spores of the fungus on the lighter, more pervious soils, beyond sufficient warmth to enable them to germinate in the following year, I am not prepared to say.

As regards remedies, I am not aware of anything which has been successful in stopping the spread of this fungus, once it has made its appearance on the plants; nor can I learn that anyone has been successful. Several remedies have been suggested, the most common being to pick off all infected leaves and burn them as soon as the fungus makes its appearance. This may minimise the evil, but, to say the least, it can scarcely be called an effectual remedy, for not only does this fungus attack Roses, but, I believe, the same kind of fungus attacks Plums, White Thorn, Poplars, and possibly other trees and plants, and the

*Bumrose and Sons, Old Bailey, London, and Derby.

worst attack I have yet seen was on that beautiful autumn-blooming plant *Senecio pulcher*, the thick, leathery foliage of this being completely coated over with thick rust, so that not only would it be necessary to gather and burn the affected Rose leaves, but the same plan would have to be carried out with other plants and trees before the fungus could be stamped out by this means—a thing impracticable, seeing how easily these fungoid diseases are distributed over a wide area by air.

Although Roses may be badly infested with this and other fungoid diseases in the late summer and autumn months, so as to completely mar and spoil their autumn blooming, I have not observed under good cultivation that the plants in the following season bloom any the worse through the attack of fungus of the previous year, or that it either lessens the quantity or quality of the bloom the following summer, and if science and practice fail to find a remedy whereby we may prevent this fungus from spoiling the second or autumn blooming of our Hybrid Perpetual Roses (for it never appears so early as to affect the first bloom), then might I throw out a suggestion for the more extended culture of the beautiful Tea varieties, so thoroughly proof against the fungus under discussion, for I have never under any circumstances seen a single trace of Orange fungus on any of the varieties of these. They are the real Perpetuals—the first to bloom, and the last to succumb to frost.

Every decade shows rapid strides in the improvement of Rose culture, and probably we may soon see a race of Hybrid Perpetuals as proof against Orange fungus as the already existing varieties of Teas. Among other fungus-proof Hybrid Perpetuals we already possess two remarkable varieties for perpetual blooming and high quality, viz., *La France* and *Ulrich Brunner*. The first named, crossed with the Teas, ought to give a race of first-class light varieties proof against Orange fungus. The latter, a model of healthy growth and vigour, and a free seeder, crossed with the pollen from the darker varieties, would probably give us a race of dark Roses, resisting both mildew and rust.

Everlasting Roses.—Is not "T. W. G." (p. 27) mixing up two distinct types of Rose, *i.e.*, China proper and Bengal? The latter consists of many varieties of most unusual colour—blackish crimson, purplish crimson, and the nearest approaches to blue I have seen in the Rose, but they are plants of small value for garden decoration. Bengals can be had in almost endless variety in Belgian nurseries, but not the Chinas.—T. S., *Newry*.

FLOWER GARDEN.

ANOMATHECA CRUENTA.

A Dainty and brilliant little Cape plant that succeeds out of doors perfectly in the south of England if it has a sheltered, sunny place in rockwork or near a south wall. The flowers are of a lively salmon-rose colour, the lower petals having a blotch of deepest crimson. The seeds, which ripen freely in England and are contained in rather large pods, are round and polished, and of a deep crimson colour, looking much like little drops of blood. It is one of the easiest grown of Cape bulbs, and one of the prettiest and neatest, the whole plant being under a foot high.

Lilies in London.—"Delta" (p. 32) is wrong in his remarks about Lilies in London. I have seen them grow well in the Botanic Gardens, Regent's Park, in Bull's nursery, and in little gardens in different parts even in the heart of London. In St. James's Park last year there were some splendid Lilies, and I have seen good specimens in a lady's garden in Montague Street, Russell Square.

Of course, every Lily would not grow in London, but the common and more beautiful kinds will do perfectly well.—W.

HELLEBORUS NIGER MAXIMUS.

MR. ENGLEHEART (p. 22) gives us a memorandum from his note-book made in March last, describing a Hellebore which he observed growing in Northern Italy (Como-Lugano). It was a strong-growing Hellebore, flower large and cupped, pure white with a slight flush of buff pink, and with pink stigmata. I think we must recognise in this description *H. niger maximus* or *altifolius*, and that herein is a most interesting record of its occurrence in its native habitat. I took considerable trouble to trace out this question in 1883, when it was found to have its home in Carniola and the valleys of the Southern Tyrol. I have since obtained plants from this locality. Mr. Engleheart's observation extends its range into the neighbouring valleys of North Italy. There

which in my experience it never does here.—W. WILKS, *Shirley Vicarage, Craydon*.

— In reply to Mr. Engleheart's query as to the variety of Hellebore found by him between Menaggio and Porlezza, I confess my inability to solve the question with any degree of certainty. The description and specially the existence of the pink stigmata naturally suggest a form of *H. niger maximus*, and though I never heard of its existence in that locality, it might nevertheless very well be found there. The difficulty that occurs is whether in Northern Italy *H. niger maximus* would be in perfection so late as March. The colour and time of year might suggest *H. antiquorum*, but this never has red stigmata, neither has *abchasicus albus*, nor in fact am I acquainted with any white Hellebore, except varieties of *H. niger maximus*, which in their natural state show this character. Can Mr. Engleheart recall to mind whether his plant resembled the niger family in leaf, stem, and shortness of pedicel or how otherwise?—T. H. ARCHER-HIND, *South Devon*.

Anomatheca cruenta. Engraved for THE GARDEN from a photograph.

are numerous specimens in the herbarium at Kew from these districts.—W. BROCKBANK, *Brockhurst, Didsbury*.

— I was in the same neighbourhood as Mr. Engleheart last March (Como-Lugano), and noticed immense quantities of Hellebores; one mountain-side was entirely covered with them, and there were blossoms enough even then to have supplied Covent Garden the whole season through. From the erect stems and huge foliage, I take the variety to be *altifolius* or *maximus*, whichever name be preferred. I noticed some with leaf-stalks over 12 inches in height, and leaves like large Horse Chestnut leaves. I brought home two plants, one a bit of the very biggest I saw, flowers pure white, touched with pink and pink stigmata; the other a beautiful clear creamy pink, precisely the shade of *Anemone japonica hybrida*, and if this latter come true here in England and be not, as I rather fear, due to causes of soil and position, it will be a great acquisition, as it was as large and strong as an ordinary *altifolius*, only of colour as I have said. I do not doubt for a moment that Mr. Engleheart's plant was a true *altifolius*, but if so, *altifolius* must surely ripen seed there,

New Chrysanthemums.—In the remarks of "A. D." (p. 34) relative to the naming of new Chrysanthemums he has omitted to note one of the greatest of all stumbling-blocks in connection with the nomenclature not only of Chrysanthemums, but of many other florists' flowers. I allude to the same name being given to two or more totally distinct varieties, a practice which seems to be on the increase, and which I am able to speak from experience causes a very great amount of confusion. "A. D." states that he is not anxious to see the raiser's name attached to a variety, because all flowers should depend upon their merits, and not upon a raiser's fame or otherwise. Certainly, that should be so, but where the same name is borne by different plants, the name of the raiser is the only distinguishing characteristic. For instance, two distinct kinds are named *Duchess of Albany*, and the same may be said of *Delicatium*, *Rob Roy*, and *Ceres*, while we have two called *M. Hoste* and two *Madame Hoste*. As new varieties, many are worthless. That good kinds have been sent out during the last few years is undeniable, yet, on the other hand, many are seen only for a season or two and then disappear. One cultivator alone offers 100 new varieties for the current year. It is therefore difficult to imagine that even one-half of them are an advance on or fairly distinct from older kinds. Of those sent out from all sources within the last three years, not more than 50 per cent. should have been put into commerce, and if from that number even all that are barely distinguishable from older kinds were expunged, the list would be very considerably shortened.—H. P.

— When new varieties of Chrysanthemums or any other plants are introduced by the hundred and accompanied by long-winded descriptions of a superlative kind, it often follows that the inexperienced are tempted to neglect old and well-tried kinds, which in reality are far superior in merit to the new sorts. In this way love of novelty means too often an actual loss of growth-force and labour. It is not alone true of flowers: it is equally true of Potatoes, as "A. D." (p. 34) will, I am sure, admit. Of one thing "A. D." seems to be unaware, viz., that we have sometimes from two to five different varieties of Chrysanthemum in cultivation under the same name. These are the produce of different raisers, and the addition of the raiser's name in these cases is a *sim qua non*. The old Tulip and Auricula growers introduced the plan of adding the raiser's name to their varieties years ago, and doubtless for the very reason that it is now so essential in the naming of Chrysanthemums. I also notice that the Primrose growers at South Kensington often add the

name of the raiser to that of their pet flowers' *Primula Rosy Morn* (Dean) just occurs to me, and may serve as an example.—F. W. B.

NOTES ON HARDY PLANTS.

Houstonia cœrulea.—Few plants of humble growth are so fully appreciated or so much sought after as *Bluets*, a name by which this little alpine is known in English gardens. We are told, however, that previous to 1830 the only common name under which it was known was *Venus' Pride*, and this name exists still in Washington territory. *Innocence* and *Dwarf Pink* are also local American names for it; near Philadelphia it is called *Quaker's Bonnet*, and elsewhere *American Daisy*, because of its plentifulness. Dr. Chapman described it some time ago as *Oldenlandia cœrulea*, a name which never, however, received general recognition. In America there are no fewer than thirteen species of *Houstonia*, seven recognised botanical varieties, and several garden forms. Probably not more than three of these are in cultivation in England at the present time, viz., *H. serpyllifolia*, *H. purpurea*, and *H. cœrulea*. Of the latter, it is said that no plant is better known in the districts where it grows wild; being amongst the first to bloom in spring, it attracts everyone's attention. It is just the same in our own gardens. It commences to bloom early in spring, and continues laden with its pretty milky white stars nearly to the end of summer, and in moist seasons even longer. I have often been afraid that it would flower itself to death; but no, it seems to carry its American constitution with it, and continues year after year to produce flowers in great abundance. It thrives best in light, peaty soil in a shady, moist situation, and, if possible, almost on a level with the eye. Plenty of water should be given it during the growing season. In the matter of propagation it is most accommodating, as it will withstand any amount of division. Our plan is to lift pieces of it, break them into small bits, and pot them singly in $\frac{2\frac{1}{2}}$ inch pots, or prick them out in boxes, keeping them there until established and planting them out where desired; 2 inches or 3 inches apart will be quite near enough, as they will soon cover the empty ground. Small pieces pricked out in the open air and protected from drip would doubtless answer just as well, although they would require longer time.

Rhodothamnus chamæcistis.—This is a really charming little alpine shrub, much resembling in its way a miniature *Rhododendron* in habit and leaves, as well as in its large purple flowers. It is perfectly hardy in our alpine garden, being a native of high altitudes in Bavaria and elsewhere. In peaty soil in a half shady, moist situation it thrives well, making dense tufts, which at midsummer or later are covered with its bell-like blooms in such profusion as to entirely hide the leaves. The latter are small, oval, dark shiny green, and covered as well as the branches with white villous hairs, giving it quite a unique appearance. It may be propagated readily by layering, and cuttings taken off at the proper time also afford a ready means of increasing it. It is a pigny shrub, with large showy flowers.

Himalayan Primroses.—In the last number of the *Botanical Magazine* (tab. 6916) illustrations of two Himalayan Primroses appear, both of which we had an opportunity of seeing at the South Kensington conference in April last. One is *P. erosa*, a plant generally known, and, we believe, largely distributed under the provisional name of *P. capitata* var. *crispa*. The specific name being that under which the seeds are said to have been received, the varietal appellation being added in the interests of gardeners owing to the distinct crispy character belonging to the leaves. The other was shown, and received a first-class certificate under the name of *P. denticulata* var. *crossoides*. In the figure above referred to, however, it has been placed as a variety of *capitata*, which, owing to the drooping habit of the flowers, it resembles. In *denticulata* the flower-heads are globose, those on the top of the umbel opening and standing up; while in typical *capitata* the flowers droop, and the uppermost usually do not expand at all. From what we already know of the habit of *P. erosa*, it

will be much easier to manage than any of the others. It is more of a perennial than *capitata* as we know it in gardens, and not by any means such a shy bloomer. K.

WHITE DAFFODIL TRIAL.

MR. ENGLEHEART (p. 34) and Miss White (p. 474) having condemned, without a trial, the *Chiswick garden*, as being unsuitable for white Daffodils, there are yet two more things which devolve quite naturally upon them: First, to prove that *Chiswick* really is as unsuitable as they assume it to be; and, secondly, in that case to suggest a better place in as public and central a position, or as near London as possible. Mr. Hartland, of Cork, grows all the white Daffodils finer and stronger than any other cultivator with whom I am acquainted, and possesses more varieties than any other grower; but there are a good many reasons why Cork should not be selected as a trial ground. There are three things which trial grounds of all kinds should possess; in a word, they should be public, central, and, above all things, on neutral ground. Of course, no thorough trial of this kind can take place without considerable self sacrifice, and the sooner we all agree to self-deney ourselves the better. What I mean is this: Mr. Engleheart says (p. 34) that "some of us will require at least two more springs for observing and sorting our plants before we are in a position to send bulbs to the trial ground, knowing accurately what we are sending." If I were to act on this plan, I should require two-and-twenty years rather than two years, and the chances are that by that time *Queen Daffodil* would have abdicated her throne, or that the influx of garden-reared plants would have quite filled up the little gaps and distinctions now observable among wild varieties. My own object in offering to send what bulbs I may have to *Chiswick* for trial is not to satisfy myself on this question. I can do that much better where I am than elsewhere, but I am anxious, so far as in me lies, to afford satisfaction to the *Narcissus*-loving public generally. What has Mr. Barr to say on this matter? And perhaps Mr. James Walker, of Whitton, will, with his usual quiet courtesy, help us with his valuable experience and advice concerning this trial. Mr. Engleheart is quite right about the white Daffodils liking to grow amongst the roots of other things. The finest plants of white Daffodil *Colleen Bawn* I ever saw were growing amongst thickly-matted roots of *Moss* and *Cabbage Roses*; and Mr. Hartland told me that when he obtained bulbs of his *Bishop Mann* they were so firmly massed and embedded among tree-roots, that he had to use a pick instead of a spade, and that many were sacrificed in exhuming them. I wish we knew exactly how, and in what root-society or underground growths the white Daffodils of the Pyrenees are found. Perhaps Mr. Wolley Dod, Mr. Maw, or some other amateur collector will enlighten us on this matter, as in gardens this seems a by-no-means-to-be-despised factor towards their well-being.

F. W. BURRIDGE.

Earthing up tree stems (p. 39).—Apart from the injury inflicted on trees by filling up earth about their stems, there is another kind of harm which such work does, and that is it greatly diminishes the beauty of a tree, and this even a thin layer of soil will do. Gardeners are fond of covering up naked tree roots and continual top dressings, earth up the stems and make the tree look as if set in the ground like a pole, thus detracting from the stability and strength which a few big, rugged surface roots seem to give a tree. I was amused the other day at seeing how carefully a tidy gardener had made little mounds around one of his big trees; his argument was that the extra coating of earth would draw up the little roots, but one might as well try to prick an elephant's hide with a pin as attempt to draw up small roots belonging to a big tree by putting soil round its stem. There is a peculiar beauty in surface tree-roots, and on no account should they be covered if ornament is the first consideration.—G.

TREES AND SHRUBS.

THE ALATERNUS.

CONSIDERING what a beautiful Evergreen this is, it is surprising that it is not more planted. The shrub that is somewhat like it, but very inferior, the everlasting Evergreen *Privet*, you see repeated everywhere, even in the gardens of those who can afford to pay the extra price for the *Alaternus*. As regards the beauty of the two shrubs, there is no comparison. You rarely see the *Privet* at this season densely clothed with leaves, whereas the severest winter does not harm the *Alaternus*. It looks to-day, after 20° of frost, as fresh and green as in May, although I know it has the reputation of being liable to become nipped by frost. The density of its leafage and its deep glossy green colour are not surpassed by any other shrub, and, added to this, it produces myriads of honey-scented blossoms in spring and often before winter has left us. Moreover, it is a rapid grower in almost all soils, hence it makes a capital hedge or screen. Its full height is from 15 feet to 20 feet, but it is only near the seaside that it reaches its maximum size. It is then a small tree. It bears the shears well, and in some old-fashioned gardens you see trimly clipped hedges of it, and it is said that when kept cut close it is rendered hardier. *Rhamnus Alaternus*, it need hardly be said, is no novelty. It was introduced from the south of Europe more than two centuries and a half ago. The celebrated Evelyn claims to have introduced it to general cultivation, and in most old garden books some mention is made of it, always recommending it. There are about half-a-dozen varieties of it, one named *angustifolia*, with much narrower leaves than the original, being the hardiest. There is also a Spanish form, and another from the Balearic Islands, and three with distinct leaf markings, the least rare being that with golden blotched leaves, which character, however, it is apt to lose, and sometimes only a solitary variegated branch on a large bush is to be seen. Though no one need be afraid to plant it in the open shrubbery, it makes a good covering for a wall, which needs to be clothed with greenery in winter, and in old places like *Claremont*, *Wortley*, *Arundel*, you may see large spaces of the walls, once called conservative walls, covered with it. Comparing the nursery price of the *Alaternus* with that of the Evergreen *Privet* shows it to be twice or thrice as dear, but this is probably owing to the limited demand that exists for it.—W. G.

The best Evergreen for London is perhaps the Japanese *Spindle Tree* (*Euonymus japonicus*), the green, not the variegated or golden kinds. In the heart of the city, in *St. Paul's Churchyard*, it looks fresher and cleaner than anything else, and as to its hardiness, the arctic spell we have just had does not seem to have made it hang its leaves even. In the *Thames Embankment Gardens* the same shrub holds its place as the best of all, and perhaps finer bushes of it cannot be seen anywhere about London than in the *Embankment Garden* west of *Charing Cross Railway Station*. There are bushes of it there 5 feet high and 4 feet through, and as dense as it is possible to have them. The green of the leaves is of the deepest, and what is important is the fact that the sooty particles in the air do not stick to the leaves, as in the case of the *Holly*, *Rhododendron*, and most other Evergreens. The *Euonymus*, too, is a fast grower; indeed, it seems but a short time since the plants of it on the *Embankment* were of nursery size. It is, moreover, one of the best shrubs to transplant, an operation which may be done at any season of the year. Shortly before the frost set in some of the big bushes of it were moved and also some at midsummer, and none of them seem in the least checked, as they had such large and matted balls. This praise, however, only applies to the green-leaved kind; the variegated-leaved forms are more tender, and no doubt severe frost will injure them. It is well known that this *Euonymus* is one of the best of seaside shrubs, but were it more generally known that no Evergreen succeeds better

in London, it would be more planted in town gardens. Another excellent London Evergreen is the Japanese Skimmia, which also succeeds in St. Paul's Church-yard almost as well as the Eucalyptus, but its leaves being broader are liable to become more begrimed with soot.—G.

THE LARCH AS A LAWN TREE.

AN old French writer says, "the Larch is admired for its pyramidal shape and spiry head, for the tender green and peculiar disposition of its foliage, and for its tassel-like catkins, which spread over the tree, and, seen at a little distance, resemble wood Strawberries in their form, colour, and size, contrasting pleasingly with the pale green of the beautiful tufts of leaves which crown the slender branches." On the other hand, Gilpin, who is generally acknowledged as an authority as regards the aspect of trees, considers it too formal in growth to be beautiful in this country, though he admits it is elegant. This writer probably regarded it only as a formal tree, when seen, as it generally is, crowded in plantations with a view to profit. We are more concerned at the present with its aspect as a lawn or park tree, and in such places it is, we consider, a most beautiful tree, particularly when between the juvenile and adult stages. At this age, if the tree has been merely sheltered, not crowded, it is feathered almost to the ground with branches. Wordsworth, who held a high opinion of the Larch as an ornamental tree says, "To produce an ornamental Larch it should be carefully nursed, removing the nurses gradually so as to allow sufficient air around the specimen to encourage the growth of the lower branches, but at the same time affording shelter enough to produce length of stem." He continues, "I do not know a more beautiful object on a lawn in the early summer months than a tree so treated, forming, as it does, a delicate Pea green cone from the Grass upwards to a height of 50 feet or even 60 feet. If properly managed, the lowest branches will live as long as the tree. Then, again, its death-like character in the winter is strikingly peculiar to the tree." In many places in this country we have seen Larches which fully justify Wordsworth's remarks, and even some old trees we have seen with branches sweeping the ground.

So much for the ornamental character of the common Larch, so common indeed that it is looked upon as a native. But beautiful as it undoubtedly is, its near ally from the other side of the Atlantic is even more beautiful. In the American Larch we have a naturally weeping or pendulous tree, not an accidental sport or monstrosity, as the majority of so-called weeping trees are, but one that embodies all the elegance of the young Deodar with the addition of being deciduous, which enhances its interest and beauty so much. It is generally admitted that the American Larch is handsomer than the European; and, moreover, possesses wood superior for lightness, strength, and durability. But it is not its utility which now concerns us. The elegance of young American Larches renders them capable of producing an extremely picturesque effect in the landscape. The branches being longer and more slender, and its leaves being shorter, all add to its distinctiveness. Therefore, in places where the common Larch abounds in plantations, this one may be planted on the lawn or in the park for the sake of variety. It is of undoubted hardiness, as it inhabits the coldest, swampy districts from New England northwards. It is known popularly as the Black Larch, American Larch, Tamarack, and Hackmatack, and botanically by several names, the chief being *Larix pendula*, *Pinus pendula*, *Larix americana*, *Abies microcarpa*, and *Larix microcarpa*. The last name is that which generally has precedence among botanists in this country, though nurserymen, as a rule, call it *L. americana*. It is a slender-growing tree, throwing off horizontal branches, and often attaining from 70 feet to 90 feet in height. It is said to be an ungainly-looking tree when old, but in a young state most elegant; the cones are larger, and the foliage of a duller hue than that of the European species. It was first introduced to this country about the year 1739 by one Peter Collinson, to whom is accredited the introduction of many a fine American tree.

There is a pendulous variety of the European Larch in cultivation in this country originally intro-

duced from the Tyrol. In this form the branches are drooping. It is, however, rarely met with as a large tree. There are other varieties of Weeping Larch which grow taller; among these are the God-sall Larch and Lawson's Pendulous Larch, the latter somewhat resembling the American Larch. W. G.

ABIES NORDMANNIANA.

A NOTE in THE GARDEN lately highly commended this tree, saying it was to be the tree of the future. That depends entirely on the soil, and it is very capricious in its tastes, liking neither a strong, cold soil nor a light, dry, sandy soil. When I first came to Cheshire, eighteen years ago, and found plenty of room for experiments in tree planting, I got a good stock of most of the established kinds of the Pine tribe, making nurseries of them. My planting extended over ten years; the trees had every chance of doing well, the ground being well drained and double dug. There has now been time to judge fairly of the results, but it would be tedious to relate them all. I will merely say that on this cold clay and wet subsoil, *A. Nordmanniana* has proved a signal failure everywhere. I have planted at different times and under different conditions in different situations more than two hundred. Some turned yellow at the points and went off at once; others were beautiful and attracted much admiration for five or six years, but finally behaved in the same way. I do not think half-a-dozen healthy specimens now survive. As a contrast to these, planted side by side with them under the same conditions, are two or three hundred *A. Douglasi*. These are now from 30 feet to 50 feet high, well furnished down to the ground, and pictures of health. The only exceptions are the tops of a few in places where they have raised their heads into the track of our furious westerly gales, which few trees can withstand. I have mentioned these two kinds as having given the worst and the best results out of some thirty or forty species I have tried here.

Edw. Hall, Malpas. C. WOLLEY DOB.

Berberis aristata.—This is a vigorous-growing Barberry of the common type, but especially noteworthy from flowering much later in the season than that kind, a circumstance which should commend it to planters. During winter, too, the leafless branches are of a bright reddish colour, and therefore very conspicuous. It is in all respects variable when grown from seed; indeed, I observed last season great differences not only in the flowering of our plants, but also in their colour. This *Berberis* is a native of the Himalayas, and is quite hardy in this country.—T.

Cratægus Oxyacantha var. semperflorens.—This is a comparatively new form of the common May; it originated in a French nursery a few years ago, and has only recently been distributed. It is a compact dwarf grower, and is throughout the summer months hardly ever out of flower. Indeed, on strong specimens, ripe fruits, green ones, as well as fully opened flowers and buds, may be found at the same time. By-and-by when this becomes better known, there is every probability that it will become a popular favourite.

Tree planting around houses.—In tree and shrub planting for ornamental effect one of the chief considerations is the arrangement of the various kinds with regard to their form, size, and rate of growth, so that when they have attained maturity they will combine and form a harmonious whole. Too often planting so as to produce an immediate effect results in an incongruity difficult to remedy or efface after the trees have become large and well established, an occurrence which could scarcely be otherwise where trees and shrubs varying greatly in rate of growth, as well as in habit, are indiscriminately mixed, often on a space too small for them, and still oftener without due regard being paid to suitability of soil or position; hence it frequently occurs that plantations planted only a few years require rearranging, and even in some instances replanting, on account of no attention having been paid at the outset to the points just adverted to. Ultimate effects are always prejudged by

those who are well acquainted with trees, and it is this knowledge that enables the experienced landscape gardener to plant in a proper and advantageous manner. But there is another point connected with planting which requires consideration, viz., the harmonising of trees picturesquely with buildings, a branch of practice which requires to be dealt with skilfully, for even with the same kinds of trees opposite effects are produced, according to the style of building.—W. G.

RENOVATING RHODODENDRON BEDS.

RHODODENDRONS are much benefited by being mulched. I once had to deal with some plants in beds which were treated as follows: In forming them we removed all the soil to the depth of 2 feet 6 inches; the natural soil was heavy and retentive, resting on clay and flints; below this, some 4 feet or 6 feet deep from the surface, was a bed of chalk. As peat or bog soil of any kind was not at hand, it was thought that a considerable saving might be effected by mixing with some peat a quantity of turf, cut and stacked some time and in a good state for use, being about half decomposed. Of this compost, viz., peat and turf in about equal quantities, the beds were entirely made. The plants—good kinds of various sizes and very healthy—were planted in spring, and during the following blooming season made a good display, but during the following winter and spring their leaves became paler in colour, and they did not grow freely the following season—in short, towards the second autumn and winter after planting they presented a sickly appearance; the leaves dropped, and they became very unsatisfactory, so much so that we determined to replant them. When the plants were taken up it was found that no fresh roots had formed, and in some cases those which they had when first planted were decayed. The soil, too, owing to the loam being of a heavy character, went together in a mass as soon as the fibre decayed, and cut out as close and solid as cheese. No doubt much damage was done to the roots by using the turf we did, as I afterwards learned that chalk had been many times spread on the surface to benefit the Grass. This had worked down into the soil and affected the whole mass, chalk in any form being detrimental to Rhododendrons.

Some good sandy peat was procured, also a good supply of sharp silver sand and yellow building sand; the plants were taken up, and the old soil was shaken from their roots, this being easily done owing to the non-production of fresh fibres. The old soil was turned over quite to the bottom of the beds, and thoroughly chopped and beaten up fine so as to get rid of any cheese-like pieces; with it were mixed the fresh materials named. The plants were then replaced in their former positions, care being taken to use some fresh peat around the roots of each. The soil was trodden firmly about the plants, but not too much so. This replanting took place early in April, and the two following months were dry; consequently what flowers were produced were of very short duration, and, not wishing to give much water owing to the rootless state of the plants, mulching with cow manure, amongst which was a good proportion of straw, was resorted to. This had been cast into a heap a few months previously, and was in good order for use. It was laid on about 4 inches thick, and just previous to doing so the plants had one good soaking with water. After this no more water was required; the soil was kept moist by the manure on the surface. Good growths were made during that season, and a great improvement in the colour of the foliage manifested itself. The following April another bed was served in the same manner, adding the same kind of peat and sand. This and also the other beds were again mulched with the same kind of manure, and during the growing season copious supplies of water were given, which washed the juices from the manure down into the soil, and, judging by the colour of the foliage and the vigorous shoots made each year, the treatment must have been beneficial.

Mulching is not practised now nearly so freely, the plants having filled their allotted space. Indeed, we have to thin in order to preserve the form of the bushes, which is sure to get leggy if allowed to grow closely together. The plants at the present time are in all respects most satisfactory. Besides its other advantages, mulching has also the effect of rendering the blooms much longer-lived than they otherwise would be, and it rots down and improves the soil. A thin covering of Cocoa-fibre refuse over the manure gives it a neat appearance if the manure is at all an eyesore. Nothing could be more perplexing than attempting to grow Rhododendrons in a soil that is in any way impregnated with chalk or lime. In such a soil they may exist for a time, but they afterwards fail. E. M.

PRUNING FLOWERING SHRUBS.

THERE are many things in shrubberies that require to be done at the proper time if a full measure of success is to be reaped, and the pruning of flowering shrubs is one of them. For the most part, the proper time is just as they go out of flower. In certain positions we have to keep the red-flowering Currant in a small state, and annual pruning in our strong soil becomes a necessity. We therefore make a point every spring, as soon as it goes out of flower, to cut back all the shoots which have flowered to within a few inches of the old wood. By doing this the branches are kept in proper form, and the plant has time to make new growth, and to get it matured for next year's flowering. In this matter it has all the character of the garden Currant, *i.e.*, it does not object to pruning, and it will invariably yield larger racemes of flower on young wood than on old.

MAGNOLIA CONSPICUA, when trained to a wall and in a good deep soil, usually makes a few vigorous top shoots, and if these were not cut away early in the winter, they should be removed in spring. This Magnolia forms spurs similar to those of a Pear tree when trained, and if they are getting so far from the wall as to require shortening back, now is the time to do it; but do not cut back too hard into the old wood, or it may not break into growth again. A safe point is to leave 6 inches of the old spur, which will invariably break out into new growth.

Where *Berberis stenophylla* is used as a climber, it is impossible to keep it in good form without pruning; but it will do the plant no harm if useless branches are cut away as soon as the flowering season is past. It must not, however, be delayed after the flowers have faded, or there will not be time for flowering wood for next year to be made. When grown in the shrubbery in a suitable soil it also gets somewhat unruly in growth, and, although one may feel reluctant to cut such a beautiful plant, pruning is sometimes a necessity.

CHIMONANTHUS FRAGRANS should be pruned in February. Young plants growing vigorously should not have their leading branches cut back until they have filled the space allotted to them, but strong branches may have all the breast-wood cut back to within 3 inches or 4 inches of the stem so soon as they have reached the limits assigned to them. This shortening back will cause them to break afresh, and it is the growth which they make next summer that will produce flowers early next year.

Concerning *Ceanothus azureus grandiflorus*, a word of caution is needed in the case of those who may not be acquainted with the treatment which it requires. Like some other good wall plants, it flowers on the young wood of the current year; and the caution I would give is, that the young growth must be preserved. Where there are vacant spaces to be covered, leading shoots must be trained there as they advance in growth; but all the other growth should be allowed to grow in its own way, as it will flower more freely and have a much better effect when not stiffly trained to the wall. As this *Ceanothus* is not quite hardy in all places, the pruning should not be done until all danger of severe frost is over. As a general rule the middle of March is soon enough, and then, if the plant is vigorous and in a warm position, all the young growth that flowered the previous year should be shortened back to within 3 inches of the main branches.

WEIGELA ROSEA, when grown in a shrubbery border, is best allowed to have its own way, and then it will flower with great freedom; but as a wall plant it requires some care in pruning in order to have it in flower every year alike. As it does not flower until the end of June, it cannot be dealt with in the same way as plants which flower two or three months earlier; but when once the right treatment is understood, it can be had in bloom every year as easily as any other. The way in which this is effected is to thin out the shoots that have flowered as soon as the blossoms fade, which will give room for the growth which is then being made.

SPIREA ARLEFOLIA for the shrubbery border is the most stately of all the Spiræas, and, when in flower, as effective as it is stately; but it must be remembered that nearly all the Spiræas are dwarf growing shrubs; therefore pruning must be avoided until they get too large for the positions assigned to them. The system of pruning should be the same in all cases. Although they do not flower all at one time, no one can err if they prune them so soon as they go out of flower. Whether the variety be *Thunbergi*, which flowers early in June, or *ariefolia*, which blossoms six weeks or two months later, how much or how little pruning will be necessary depends upon the size and condition of individual plants. As a general rule, a judicious thinning out of the branches is all that is necessary, except in the case of those that are getting too large. Then a somewhat severer cutting back may be given without running any serious risk, as the centre of the plant should in such cases be left untouched for one year.

As the single-flowered varieties of *Kerria japonica* are getting fashionable, a brief reference to them may not be out of place in this list. We find that, grown in bush form in the mixed border, they do not thrive so well as one might wish. They make more growth than is desirable, and there is a proportionate scarcity of flowers; while in another garden not far distant, where this plant is trained to a wall, it makes less growth and flowers more freely than our plants of it do which have more room. As it is a very hardy plant, the pruning should be done in autumn; all that is required is to cut away some of the old wood, leaving the last season's growth its whole length.

THE GUELDER ROSE (*Viburnum Opulus*) is another plant that when allowed to grow in its own way flowers more freely than when pruned, and is more effective when large than small; but that is no sufficient reason why it cannot be had in small gardens more generally than it now is, for it is as amenable to pruning, in order to keep its growth within certain limits, as any other shrub. As soon as the flowering season is over, the long growths should be headed back, and where the branches are too thick they should be thinned out to make space for young growth, for it is on the growth made during the current year that it flowers the next season. C.

The Copper Beech.—This tree is undoubtedly far too often planted haphazard. Little regard is paid to its grouping, even if a thought is given to soil or to the danger of overcrowding. The consequence is that we have many well-grown specimen trees of it, whilst we seldom see an effective tree group. Beautiful in itself, no tree can more readily have its beauty enhanced by judicious arrangement than the Copper Beech. I have no more pleasing recollection of a sense of colour than that of the sun shining on a well-shaped Copper Beech in happy proximity to a Laburnum. This is a much-to-be-commended coupling. The homely white clusters, too, of the Snowball tree (*Viburnum Opulus*) have their beauty much intensified by a background of Copper Beeches, adding richness to their own bright green foliage, as a velvet mount sets off the grace of a Wedgwood plaque, and if it be not gilding refined gold, I may even add that the queen of the woods herself, the Silver Birch, seems to have an added glory even from a copper frame. For a neighbouring large tree nothing can surpass the common green Beech, simply on account of its spring-tide verdure. As accompanying underwood, I will only mention the Broom, the Furze (double), and the Bracken. The Copper Beech reminds me of that little known tree, or rather, let us say, shrub, the Copper Hazel.

Neat in habit and iron in constitution, it is, in my opinion, an admirable variation on the Holly, Laurel, and Hornbeam fences one sees often enough. Pleasing as these latter are, variety is so also, and I never remember seeing but one hedgerow of Copper Hazel.—S. B.

GARDEN FLORA.

PLATE 579.

IRIS AUREA.*

THIS stately, late-flowering, golden-yellow, beardless Iris is a native of Cashmere. It was first described by Lindley (*Botanical Register* t. 59) after plants raised from seed brought by Royle from that country, and was a few years ago re-introduced into cultivation by Dr. Aitchison, who found it growing near Shrinuggur, in the same country. I am not aware of any habitat outside Cashmere having been recorded. It possesses all those marked general features which characterise the spuria group of Irises (*I. spuria*, *notlia*, *Güldenstädtii*, *ochroleuca*, *Monnieri*, &c.). Thus, the rhizome is hard and compact rather than fleshy, and the terminal bud gives a piece of the rhizome when dried the appearance not unlike that of the not too curved rough end of a walking-stick; the tall leaves, somewhat narrow, 4 feet or more in length, are strong, stiff, and pointed, and die down completely in winter; the strong and stiff, but relatively thin, tall scape bears a terminal bud of two or sometimes three flowers, compressed within the long, stiff, spathe valves, so that there is hardly room for the two flowers to expand together, and also bears a similar lateral bud; the flower is beardless, rigid; the fall, with a narrow claw separated by a notch from the wider blade, spreads horizontally, the style being closely pressed down over the claw of the fall so as to leave a very narrow, almost perfect, tunnel down to the nectary, while the somewhat narrow standards are erect or slightly connivent; the ripe capsule is large, oblong, more or less beaked, with three conspicuous longitudinal ridges, each of which is double; the seeds, which are numerous, are compressed into discs (except the upper and lower one in each *loellus*, which are conical or pyriform), and possess very loose, wrinkled, white, grey, pink, or sometimes black coats.

All the various members of the spuria group possess these characters, and the question may be raised whether they do not really form one species; but *I. aurea* may be at once distinguished by the golden yellow colour of all parts of the flower, and by the blade of the fall being a long oval with peculiarly crimped edges. In *I. Monnieri*, to which *I. aurea* comes nearest, the blade of the fall is a more rounded oval with even edges; the whole flower is of a paler yellow, more nearly of a lemon-yellow, and the flower, spathe-valves, and foliage are all larger and broader. In the other members of the group the flower is white, blue, or purple, or at best a dingy yellow, and in *I. spuria* and *I. Güldenstädtii* the flower is smaller and narrower, as indeed is the whole plant.

Like nearly all the spuria group, *I. aurea* seems to me to do best in rich, fat, damp, somewhat stiff soil, but it will also flourish in lighter soil if adequately damp, and will thrive in places far too dry for the *I. virginica* group or for *I. Pseud-acorus*. It will repay with bloom rich feeding, provided that the manure be adequately rotten and digestible; and for the full development of its beauty full sunshine is needed. I imagine that in cold climates it will not do so well in an

* DRAWN FOR THE GARDEN IN M. Godefroy-Lefebvre's garden Argentueil.

IRIS AUREA

actual peaty bog as in damp, though not absolutely wet, rich loam; but on this point I cannot speak from experience.

It flowers late in the summer, about the same time as or a little after *I. Kämpferi*, and a little before *I. Monnierii*. It bears transplantation at almost any time, but is best moved immediately after flowering; for though the foliage may die down owing to removal, the autumn rains stir up the rhizome to send out new roots, and indeed new foliage, so that it gets firmly established before the hand of winter is upon it, and consequently starts vigorously in the spring. Seeds sown as soon as ripe, in October for instance, will germinate freely the next year, and the seedlings will flower freely in the third or fourth year, sometimes in their second year.

The flowers open well when a spike is cut in the bud, and being stout last a good while. Hence the plant may be made very useful for decorative purposes. M. FOSTER.

FRUIT GARDEN.

WINTER PEARS FROM WESTERN NEW YORK.

MESSRS. ELLWANGER & BARRY, of Mount Hope Nurseries, Rochester, New York, sent us a very interesting collection of Pears, with the following note:—

We send you to-day (9th December) a small box of Pears as an experiment. We desire to ascertain whether it is practicable to ship Pears to London at this season of the year. Be kind enough to inform us on their arrival what condition they are in, and what time they have been on the way. September was very wet here, and Pears ripened sooner than usual; those which we usually keep till 1st January are already sent to market. November was a wintry month here—far more so than usual, there being heavy falls of snow and hard frost. The weather now is, however, mild, and the frost so far out of the ground that we can dig up trees. The Pears sent are as follows, viz.:—

6 Easter Beurré	6 Josephine de Malines
6 Anjou	6 Winter Nelis
6 Beurré Gris d'Hiver	4 Lawrence
6 Columbia	3 Duhamel

Owing to certain delays, caused by agents or some misunderstanding, the Pears did not arrive until the 5th of January—nearly a month after they were despatched. They were not sent in what we consider, from our experience of the London markets, the best way to ensure their safety, and this is not surprising in an experiment of this sort made under unknown conditions. They were sent in a rather deep box, and unfortunately the pressure left a space between the fruit and the lid, and the consequence was that the fruit was knocked about considerably during the long and perhaps stormy voyage. Notwithstanding this, and that a great many were battered and almost unrecognisable, some very fine fruits of the best kinds came to hand safely: and we have not the slightest doubt that if sent in shallow trays, each fruit wrapped up carefully in paper, and all packed carefully with paper shavings, so that they could not move about, no matter what vicissitudes they went through, such fine fruit as Easter Beurré would arrive in a perfectly safe condition—as safe, practically, as the fruit that comes to us from Western France, and they would in that condition find a ready market in London, bring a very high price, and pay the American fruit-grower much better than Apples, because the climate of England and Western Europe, while it permits of the perfect growth of the Apple, and of as fine specimens of that fruit as can be shown, is not nearly so suitable as many parts of Eastern America for ripening the Pear, which is never seen at its best except in a climate some-

what better than that of England or Northern France. These remarks refer particularly to the fine market Pears, such as the Duchess or Easter Beurré, which bring the highest price in the London market, and, as we think, are worth it. The Pears that travelled most successfully were those referred to below.

JOSEPHINE DE MALINES.—Large, perfectly formed, and most excellent in flavour—such fruit as we rarely see of this variety, first-class in every way. For it, we have no doubt, an excellent market could be found in London.

EASTER BEURRE.—Very handsome large specimens of these, somewhat injured, however, but sufficiently good to show that with ordinary care in packing this fine Pear now sent to us from France could be sent here from America, and would find a very healthy market in London when fine winter Pears after Christmas generally bring a high price. We should say that such specimens as these are well worth 1s. apiece. The flavour was not quite so good as that of the best French samples, but we tasted the fruit immediately after the voyage for the sake of seeing how it travelled, and did not try to bring it to maturity. We have not the slightest doubt that these would hold their own with the very best French Pears, and in size they are better than those to which we are accustomed.

WINTER NELIS.—Handsome brown specimens, larger than those usually seen in the London market. Much battered about, owing to loose packing, but having all the precious qualities of this fine winter Pear.

BEURRE D'ANJOU.—Beautiful specimens of this, with a clear, waxy skin and handsome form, travelled well. Although of fair flavour, not to be classed with the others in respect to quality. The flesh is juicy and melting, but it lacks the fine high quality of the first mentioned. We believe our American friends think highly of it. Another Pear of delicate flavour is Columbia.

PACKING FRUIT FOR TRANSPORTATION.

Messrs. J. W. Draper and Son, of Covent Garden, inform us that such fruit as is sent from America should be packed in single layers in cases of half-inch clean deal. The dimensions of the case—which must not vary in size—should be, length 18 inches, width 12 inches, and depth 5½ inches (outside measurements). Each Pear should be wrapped separately in tissue paper (with which also the case should be lined), and a sufficient quantity of paper shavings should be used to prevent oscillation, absolute firmness being essentially necessary. All the fruits in a case should be uniform in size; the number it contains, eighteen, twenty-four, or thirty, as the case may be, together with the name of the fruit (thus: E. B. for Easter Beurré, W. N. for Winter Nelis, &c.) should be stencilled outside each case. Despatches of irregular numbers, or Pears of irregular sizes, or careless packing will surely have a bad result. Too much care cannot be taken in the packing, and the result compensates for the expense incurred, as the fruit would be sold in good condition to willing buyers. The name of the firm to whom the cases are consigned should be marked plainly on the box, while the consignor should have a distinctive brand, by means of which he could find a reputation, which would be of the greatest service to him in getting a good market. Shipments are best sent *via* Liverpool to London, as this route is quicker and not so expensive as sending to London direct, the dock dues, &c., and expenses from Liverpool being 3d., while those of London are 10d. per cask, &c. As regards the general question of the demand for winter Pears in London, we think it is practically

inexhaustible, and it is not now fully met by supplies from any country. At the time when this experimental package comes to us the supply of French Pears has virtually ceased, and no other country meets the demand for this fruit. It would not pay American growers to send us early Pears, but Pears of these fine old kinds are perhaps the best and most paying fruit that could be sent to us.

APPLES ON THE PARADISE STOCK.

"I AM planting a large piece of ground with Apples on the Paradise," said a Middlesex grower the other day, "because I am assured that in that way I shall get the finest fruit, and only good fruit will pay to grow." This statement comes from a grower whose opinion is certain to be received with respect. There remains, however, the important question of the endurance of the Paradise stock, especially if actively engaged during a series of years in producing exhaustive fruit crops. Now, where too liberal an expenditure is indulged in by growers under the impression that the Paradise stock is to bring back the command of the Apple market, it would be well if those familiar with this stock over a considerable number of years would furnish some proof that it would endure not merely for a few years, but for a lifetime. I have no intention to imply that these dwarfing stocks are essentially non-enduring, but there can be little doubt that the French Paradise did prove so exceedingly restrictive, that after the lapse of a few years it has almost invariably become a failure. The so-called English stock, a broad-leaved Paradise, without doubt gives more robust growth whilst still developing early fruitfulness. What remains to be shown is that this stock, if not so long lived as the Crab, will at least endure through an ordinary lifetime, for it will never pay to plant over a wide area of ground Apple trees which are not to be as prolific twenty-five or thirty years after planting as at five or ten years after planting. Very likely some will advise that along with precocious fruiting Paradise trees shall also be planted standard trees on the Crab, and with that action I agree, because there is then due provision made against failure on the part of the dwarf trees. The assumption that the two forms will not thrive together remains to be proved, but there is no more reason why dwarf Apple trees should fail beneath standards than that Gooseberry or Currant bushes should, and these latter, it is known, seem never to thrive better than in such company, as may be seen in hundreds of market orchards and over thousands of acres of land.

There are seasons when the protection of top trees proves valuable to the dwarf trees below, and if the bloom on the standard trees suffers, the loss is considerably minimised if the sacrifice above has saved the crop below. I remember a practical fruit grower saying not so long ago that he would never become tenant of an old orchard, because the trees, being thick, were all top and had no sides; hence, had all the bloom exposed to the weather. No doubt that is often the case, as it is found in the pruning and thinning of old trees that the lower branches must be from time to time sacrificed to the spreading top. On the other hand, if the centres of the heads be cut out, in the hope of promoting side growth, then the only result is a lot of strong young shoots, which must either be thinned, the best being left to form a fresh centre, or must be removed altogether. When an orchard consists of all top trees, of course they are permitted to remain thick, because this top crop is almost the sole crop. But when dwarf trees on the Paradise stock are planted beneath, there is ample inducement to keep the standard trees thinner, and thus side branches are encouraged as well as top ones.

The dwarfed trees ensure the production of the finest fruits, first, because the roots exist in the richer portion of the soil, and second, because there is a less tendency on the part of the trees to produce useless wood. For all early market purposes the

finer the fruit the better, because good samples always mean the top price. On the other hand, it is very doubtful whether these large samples are so useful for keeping as are more medium-sized fruits grown rather more slowly and on older trees. Thus it is well to advise the planting of dwarf trees for early supplies, but on the whole it is most probable that well-established standard trees on the free stock produce the best keeping because the more slowly grown fruits. I do not assert this to be a fact, but incline to the belief that such is the case. The metropolitan market growers are in favour of early kinds, and of kitchen Apples, large fruiting ones, chiefly for the following reasons: First, the early season finds less competition, and, of course, rather the best prices; second, the trees get early relief from the crop, and are by no means so much drained as are trees which carry out a good crop till so late as October; and third, the samples of early kinds are almost invariably the larger. I might have added that late kinds, if to be sold in plentiful seasons at a remunerative price, need storing and sampling, entailing much cost and trouble, which may not be repaid. It is held preferable to gather and run into market direct, even if there be some reduction of profit, than to store and take many risks.

It is thus evident that the London public must look to the provinces for stocks of late-keeping Apples, and these stocks are best furnished from districts where Apples thrive fairly well, and that is a very wide area indeed. Having regard to the fact that we import American and Canadian Apples in such enormous quantities, it is evident that there are seasons when our home supply must fall very short indeed of the demand. To meet that demand, it seems odd that landowners have not taken the Apple in hand and planted it largely either on their own account or on behalf of their tenants. A little saving in costly pastimes would soon pay for standard Apple trees, and it is very possible that tenants would gladly find land and labour for planting. Certainly several years would elapse ere the general cropping of the ground was interfered with by the trees, and when it was, then it is evident the trees would be producing fairly remunerative crops. No doubt our climate is so unstable that, plant as we may, we cannot ensure crops with any certainty, but the probabilities are in favour of good averages, and where the outlay is so small the average produce should be profitable. Certainly there is no reason why a million or more of Apple trees should not be planted in proper districts at once, and with a few more such plantings in future years we ought to be able to furnish less favoured nations with Apples rather than be so largely dependant upon America for our winter supplies. As a rule we are too sparing of the saw and hook in dealing with standard, and especially old trees. Not merely is a good thinning needful over five-sixths of the Apple orchards of the kingdom at once, but such hard thinning is imperative if good samples of fruit are to be had at least every two years. Myriads of trees need now that one-half their heads should be cut clean out, and if that were done, the character of the fruit sample would soon be wonderfully improved. I see in the Middlesex orchards the most distressing absence of the saw where plenty of labour might be profitably furnished and ample wood obtained to pay for that labour. One reason of the comparatively poor price returned for so much of our home-grown fruits is because of the indifferent size of the sample. The Canadians send us their best, and if we are to compete with them we must grow the best only, and that, too, of kinds which give fair average quality. Canadian Apples have rich colour and much beauty, but I know of none which excel our best Blenheims and Wellingtons for quality. A. D.

Barking Vines.—It takes a long time to get rid of established customs, but annually scraping the bark off Vine rods is about as useless work as one can well engage in, and when carried to excess is

positively injurious to the Vines. This sort of work is, as a rule, done by young men and boys, and although the directions to only remove the really loose bark may be partially attended to, it is fortunate if any rod escapes without the inner bark being broken and more or less injured; therefore the sooner such work is discontinued the better. The insecticides commonly used now-a-days are sufficiently powerful to exterminate any living thing on the Vines. This scraping business used to be a heavy item in the garden expenditure. I have myself spent weeks at it at this time of year. Now, however, we simply dress the Vines and leave the old bark to fall off naturally; thus we are gainers in all ways, *i.e.*, we have better Grapes and a lower labour account; in fact, the prices at which Grapes are sold now-a-days will not pay for scraping.—J. G. H.

HOME-GROWN V. FOREIGN FRUITS.

If foreigners can send fruits here and find a ready market for them, all we have to do is to grow as good an article as they do and one that will suit the daily wants of the masses. "We do not want dry American Apples or tasteless Tomatoes," say the public; "we will rather pay the extra price required for home-grown produce." Now there must be good grounds for this decision, for the appearance of foreign fruits is usually inviting. British fruits have got a reputation for good quality, and therefore growers must not only keep it, but improve it. The question then arises, what shall they grow? Well, for open-air culture nothing yields so good and speedy a return as

APPLES.—I have therefore for the last few years been planting young Apple trees instead of vegetables and bush fruits, finding these already overdone. Of course, there are times when common soft Apples, such as Codlins that will not keep are very low in price, but the orchards of the future must be stocked with a better class of fruits than one frequently finds in old orchards. Not that old sorts of Apples are bad; on the contrary, we are not likely to have anything superior to some of the oldest of Apples when well grown—and by well grown I mean when the trees get constant attention to clearing them of useless spray that chokes the good bearing wood, when Moss and Lichen are got rid of, American blight and other insect pests destroyed by a thorough dressing of paraffin oil, the best and cheapest of insecticides, and when the roots find plenty of rich food on the surface and are not driven down into cold or water-logged subsoils. The modes of pruning or training may be made to suit the varied tastes of cultivators, for if other conditions are favourable, whether the tree is confined to one shoot or cordon or spreads into a widely branched head, good fruit will be borne. The only difference is that cordons will produce a few grand specimens, while the latter will yield a full crop of average sized fruit. In the sheltered valleys in Kent, where the soil is strong and holding, the large standard is the form adopted, but here, in a wind-swept locality and shallow dry soil, dwarf bushes suit best. Of varieties, let Lord Suffield be the type for early culinary use, and for a late supply Blenheim Orange, Lord Derby, and French Crab. For dessert, Red Quarrenden, Golden Pippin, Cox's Orange Pippin, Court Pendu Plat, and others of that type always command a ready sale. Storing of late sorts ought to be more carefully done than it is. Why are sorts that would keep until the new year sent to market and sold for half their value? Why, simply because growers have frequently no storeroom, and their holdings are of too precarious a kind to induce them to erect buildings of any sort, for which they would get no compensation when leaving.

As to Pears, if anyone wished to form an estimate of the demand for them, they should watch the cargoes of boxes that come from France of Williams' Bon Christien and other popular sorts, and take note of the prices which they realise. I do not, of course, say that every county in the kingdom is suited for producing good Pears, but

I am certain that there are thousands of acres in the southern counties that would grow Pears quite equal in quality to those that are imported. But the old-fashioned Swan's Egg, Windsor, Lammas, &c., although useful in some cases, are not the varieties to drive the foreigner out of our markets. We must go in for dwarf bushes, cordons on walls of any kind, either brick, board, or any other material, so long as the sun's rays are fully utilised. I had fruit last season from pyramids of Pitmaston Duchess that realised 3*l.* each; such fruits are certainly far more profitable than bothouse Grapes. Pears must have good culture; the fruit must be thinned; good store rooms must be provided. If anyone wants to see really good home-grown Pears they should go to Petworth in autumn, and Mr. Breeze will show them what well-grown Pears really are.

As to Plums, it may seem folly to talk of growing more of them when so many were left to rot on the trees last year; but the fact is, growers have over-done the common mid-season kinds; really good early, or, better still, very late sorts pay well. The best for late work is Coe's Golden Drop; it is one of the best of dessert fruits when the glut of other kinds is over; for Plums wooden fences would answer perfectly. Damsons, although so plentiful in some parts, are by no means well grown in others; at the time when they were hardly paying market expenses in London they were realising good prices here; had railway rates not been so heavy, any quantity of them could have been sold here.

Cobnuts, Filberts, and Walnuts are unequalled by those imported, and home-grown ones in provincial towns rarely fail to meet with a ready sale. It is surprising that, when land of good quality is uncropped, such a valuable tree as the Walnut should be so much neglected. Its crop is not only profitable, but it is such a valuable timber tree as well. Landowners who have a small nursery ground could easily raise their own stock of trees, and thus permanently improve their estates at trifling cost. The fact is we let our trees stand so long that they get hollow and worthless, and then we send abroad for a supply of the very Nuts we can produce equally well at home.

Tomatoes, whether grown under glass, on walls, or in the open air, are the crop that one feels sure of not over-doing—at least for some time to come, and the difference between home-grown and imported ones is nearly 100 per cent. Last season the price for home-grown fruit was 8*d.* per lb. for a long time, and only for a short time was it as low as 6*d.* per lb.; while foreign Tomatoes could be had in any quantity for 3*d.* and 4*d.* per lb. The demand increases so rapidly, that it is evident everyone is becoming a consumer of Tomatoes.

Grapes are now sold so cheaply, that one can hardly recommend an extension of their culture. But if any branch of the trade proves a good investment, it certainly is that of the latest keeping black sorts, such as Gros Colmar, Alicante, Lady Downes, or Barbarossa. These realise good prices after Christmas, and where their culture is well attended to they are by no means a bad investment. Selling the produce to advantage is certainly quite as important as growing it in the best way, and there is no valid reason why much of the goods now sent to the salesman could not be sold direct to the retailer, if not to consumers, if growers would only take the trouble to do it. Of course, sending to London makes it compulsory to sell through a salesman; but London does not monopolise the markets of the kingdom, and new starters will find it advantageous to study the requirements of sea-side and provincial towns more than they have done. J. Groom.

Gosport.

5740 **Woodlice & fruit.** "R." cannot do better than trap the woodlice. Small garden pots laid on their sides with a piece of Potato, Turnip, or Apple at the bottom, and half filled with dry Moss, form very useful traps. Potatoes and Apples cut in halves and partly scooped out, placed with the hollowed-out part downwards, so as to allow the woodlice to creep under them, are also worth trying. Woodlice may be poisoned by boiling small pieces of Parsnip in water in which

a little arsenic has been dissolved. Care should be taken not to allow any other animals to have access to the poisoned Parsnip. Toads are very fond of woodlice. G. S. S.

SEASONABLE WORK AMONG FRUITS.

W. COLEMAN.

THE advent of the jubilee year will long be remembered by gardeners if by no other body, for hardly had they commenced clearing away the magnificent branches snapped off their Conifers and Evergreens when a dense black fog overspread the land, and the temperature gradually sank lower and lower until the thermometer on the evening of the 1st touched 7° Fahr., or 25° of frost. This, fortunately, was the lowest point, for the wind by this time had veered round to the south, a falling barometer told us we were nearly out of the coil wave, and ten hours later the figures were reversed, the thermometer standing at 25°, or 7° of frost. Cold rain is now falling, and the snow which has been quite a God-send to vegetable gardeners, although a demon amongst ornamental trees, will, we hope, soon leave the ground clear for further pruning operations. It is not, however, a good plan to prune in severe weather, neither is it wise to tread upon the soil, be it light or heavy, immediately after a thaw, but there are ways and means where there is a will, and those who have the misfortune to be behind must fall in where treading the wet ground will do least injury. All wall paths, for instance, may be lightly covered with long litter from the stables, and the pruning and nailing of Morello and other Cherries may be completed. When finished, soap-suds or other washes of lime or soot may be syringed over not only the trees, but the walls also with the greatest possible advantage. A dry day should always be selected for this work, and in order to thoroughly penetrate old walls whose joints are faulty, a stout garden engine will be found preferable to the syringe. Plums, Pears, Apples, and bush fruits in like manner may be washed once, twice, or as often as the supply at command will admit. Years ago it was the practice to paint choice trees, including Morellos and Peaches, with the old-fashioned mixture of soap, sulphur, lime, and clay, and in not a few places that finest of all insecticides—glutinous soap-suds, which cost nothing, were allowed to run to waste. All this is now changed, at least in well managed gardens, and fruit trees of all kinds show by their bright clear bark and spurs how thoroughly this material suits them, both as an insecticide and a manure. Soap-suds may be used pure and simple direct from the laundry, but I prefer keeping them for a few days or weeks in open-headed casks, and applying them to the trees and walls on dry, mild days. The soap, soda, and other chemicals known only to the female craft then form a fine glaze on the wood and flower-buds, which renders the latter impervious to the attacks of feathered vegetarians.

BUSH FRUITS.

We at one time left all our Gooseberry bushes unpruned until the spring, but this delay is no longer necessary, as birds do not seem to relish the saponaceous addition to their favourite food. But why prune Gooseberries and Currants to within an inch of their destruction when it is a well-known fact that unpruned trees often bear full crops of fruit where hard spurred skeletons fail? Some thinning to let in light and air and favour the introduction of the hand is necessary, but the less trees are spurred and the longer the outward extending shoots are left the finer and heavier will be the crop of fruit. Some years ago, having two long rows of condemned trees, they were left unpruned and the crop was excellent, whilst others from which all the superfluous wood had been cut away were a perfect failure. Although made secure against birds, a late spring frost destroyed the exposed fruit when in flower. It cuttings of bush fruits were not put in early in the autumn, straight, well-ripened pieces of wood should now be selected and heeled in as soon as the weather becomes favourable. Bushes can be bought at a cheap rate, but from only a few nurseries can trees equal to those of home manu-

facture be obtained, and for this reason every gardener should put in a batch of cuttings every year. If not wanted for home use, help and encouragement can be given to cottagers and tenants by an annual distribution of surplus trees. When bush trees are pruned, they should be well top-dressed with manure, fresh compost, or burnt refuse, as opportunity, in the way of weather, favours wheeling ready for forking in when the soil is in suitable condition.

RASPBERRIES.

too, may be heavily coated with light, rich manure, leaf-mould, peat, lime rubble, or charred refuse, but on no account must the borders be forked or dug, as the most valuable roots run close to the surface and quickly resent disturbance—I may say destruction. If still undressed, no time should be lost in getting them staked and tied, topping being deferred until the buds commence swelling in the spring. The modes of training Raspberries are numerous, but good rustic stakes being plentiful, I question if the old-fashioned system of placing three to each stool and equally dividing the canes is not as good as any. Much, however, depends upon the nature of the soil and the surroundings. If cold and heavy, single rows running from north to south and trellis training answers well; whilst on hot, dry land planting in blocks may be preferable, as the bushes shade and keep the ground moist and cool—no unimportant matter in the growth of fine juicy fruit. In model gardens where taste prevails, we often see Raspberries festooned or trained in the form of arches, and for this mode they are planted from 4 feet to 6 feet apart. When thoroughly established, a stake is driven in midway between the stools; half the canes belonging to one stool and half of those from the stool on the opposite side of the stake are then bent over towards each other and firmly tied together, also to the stake, to keep them in position. The advantages are neatness, security from wind and birds, as the major part of the fruit hangs beneath the arches, and economy in stakes where these useful articles are scarce. The Raspberry in many gardens is much neglected, and yet I question if any of our most valuable fruits can be turned to so many uses in our daily economy. Possessed of a delicious aroma, it is universally used for flavouring our earliest fresh fruit tarts, for jams, for raspberry vinegar, brandy, wine, and ices, and for the dessert it is most grateful and wholesome. To prolong its season, Cutbush's Prince of Wales should be planted in the warmest part of the garden for coming in early; Carter's Prolific for the main crop, also on a north border for succession, and, space being unlimited, the strong-growing Semper Fidelis, which comes in a fortnight later than the others, should have a place for leading up to the autumn bearers.

APPLES.

Now is a good time to wage war with American blight on infested trees, that is, provided they have been pruned and trained, and every old cankered branch that can be spared has been cut out and burned. We sometimes hear of the restoration of debilitated trees by heading back, but all cannot afford to decapitate, and unless the branches are very badly cankered, I should prefer pruning down the affected parts and painting with a strong emulsion of Gishurst compound and paraffin in the proportions of 1 lb. of the first to a wineglassful of the second. If preferred, the tar mixture, half a pint to a gallon of stiff loam and reduced with boiling water, answers equally well. One or other of these mixtures should be thoroughly worked into every old spur and wound before the sap begins to move, and a close watch must be kept upon the trees when insects that have escaped return to activity in the spring. The winter dressing will destroy the greater part, but in order to make a complete clearance the remnant must be waylaid as they emerge from their winter fastnesses. Newly grafted trees that have been allowed to grow to their fullest extent will now require attention. If the scions have

taken well and are considered capable of receiving the rush of sap from the stocks, all spray which has been allowed to grow wild throughout the past summer may be cut away, otherwise, the stocks being large and strongly rooted, shortening back will be found preferable to complete removal—at least, for another year. When this clearance has been made and extra strong growths have been shortened to secure evenly balanced heads, all old clay and ligatures must be cleared away, when the largest limbs still showing bare wood may be well plastered with fresh clay and cow manure. A mixture of this kind having wonderful healing power keeps out the elements and favours the completion of the union, always provided the trees are free from woolly aphid. If this existed on the stocks before they were grafted, or has been introduced with the scions, there, beneath the old clay, a colony will be found awaiting the tar or Gishurst mixture as a preliminary to the application of the healing mixture of loam and cow manure. Finally, all strong grafts, especially in situations exposed to wind, must be made safe by means of light stakes driven into the ground or tied to the main branches. To these the scions can be secured by light, tarred twine, but it will not be wise, at least for the present, to draw the young shoots out of their natural line of growth, as the slightest pressure frequently leads to their separation from the stocks when the sap begins to flow. Where grafting in the spring is contemplated, good scions should now be selected from clean, healthy trees, labelled and laid in under a north wall. The heads of trees about to be operated upon also may be partially cut back, leaving a foot or more of wood to be cut off each branch when the grafts are attached. A dozen grafts will quickly form a good head, but where the stocks are more than an inch and a half in diameter I prefer putting two on each shoot for the twofold purpose of getting the stump quickly covered with new wood and forming a great number of channels for the first flush of sap. These eventually may be reduced to one, as the strongest not unfrequently forces the weakest out of position when two are left.

PEARS.

Being more precocious than Apples, are first ready for grafting, and for this reason the selection of scions should be made forthwith. In all other particulars the preparation and manipulation of the two are identical. American blight, fortunately, does not attack the Pear, but the small grey scale, the exact colour of the bark, often produces a hide-bound and encraving condition before it is detected. Trees worked on the Quince and planted against hot south walls are most subject to it, and speedily assume a hard, stunted look, especially if the roots are allowed to feel the want of water. A mixture of loam and Gishurst compound, or soft soap and lime well worked into the old stems and branches, generally settles the account at one dressing; but in order to prevent a return, the trees should be generously mulched and copiously watered throughout the growing season. Last, but not least, the saponaceous wash should be freely and frequently plied from the time the leaves fall until the buds commence swelling in the spring. Pears, like all other fruits, become a ready prey to insects under starving treatment, and soon recover their health and vigour when these conditions are reversed. When well planted on open quarters or in good orchards, the rainfall, combined with annual top-dressing, generally keeps the roots moist enough, but no matter how well a wall border may be made, there are periods when copious supplies of water passed through heavy mulches become absolutely necessary.

PEACHES.

The ground at the present time is deeply covered with snow, and the severe frost which set in at Christmas, fortunately before we commenced detaching our trees, will delay this work for the present. But whenever the change to milder weather sets in, every nail will be drawn and

cleansed with fire, and the branches, after being carefully washed, will be made secure to upright poles a foot or so from the walls. Pruning having been performed immediately after the crop was gathered, the final dressing over will be deferred until the time arrives for nailing in. Meantime advantage will be taken of dry days for washing the walls with quicklime, soot, and sulphur, with a little linseed oil added, and a sufficient quantity of Venetian red to produce a warm old brick colour when dry. To some the removal of every shred and nail, and drawing the trees away from the wall, may appear superfluous labour, but a Peach tree worthy of the name requires re-training every year, and I can assert that the time devoted to this work in the winter and early spring is paid back with interest in more ways than one. In the first place, a new start is made with the wood and walls quite free from the larvæ of insects; consequently dressing to destroy the myriads of aphids which spring into life almost before the blossoms are open is avoided. The young shoots grow on freely without undergoing a check and ripen early, and the fruit, well sheltered with fresh healthy leaves, generally escapes late frosts and swells to maturity. In the second, detachment enables the pruner to examine his trees thoroughly, and after cutting out every bit of cankered or faulty wood, they can be trained into perfect form and balance in much less time than it would take to alter unwashed trees whose first growths get crippled by insects, and, independently of the check to the fruit, the second do not have time to ripen. The seasons of late many people think less favourable than they were in their boyhood, and some assert that the fruit is not so large, but this, I think, is a very natural mistake, and so long as good crops of the finest late Peaches can be obtained from properly managed trees, our time may be better employed than in dwelling upon the past.

APRICOTS.

If these have not been pruned and trained I would suggest their being allowed to stand over until the weather breaks. Meantime the materials for protecting the flowers should be prepared and in readiness for hoisting on the shortest notice. Apricots, especially Moorpark, are neither satisfactory nor profitable, and, try all we may, large branches in otherwise healthy trees die off annually—I ought to say towards the latter end of the summer. All the theories hitherto put into practice have not arrested the disease, by some supposed to arise from sunstroke, by others from the action of frost on the sap vessels. If either of these causes is correct, our trees after mild winters or cold, unless summers should be free; but such is not the case, as a year never passes without leaving its mark upon the finest trees in the best managed gardens throughout the kingdom. I have often thought that mildew to which the Apricot in warm, dry soils is very subject, may affect the shoots when young, and although they do not die off at once, the time comes when the roots in a dry soil cannot supply, and the damaged vessels cannot allow a sufficient quantity of moisture to pass into the leaves beyond. Prevention of mildew, if this theory be correct, must be secured at any cost, but sulphur, the usual remedy so long as the roots are dry is only temporary in its action; hence the importance of supplementing it with copious supplies of water and heavy mulchings. In almost every work on the management of fruit trees we are told the Apricot should be well watered in the spring, but well acquainted with the fact that this tree evaporates an immense quantity of moisture from its leaves, it is only reasonable to assume that August and September are the best months for thoroughly soaking the soil down to the drainage. In fact the Apricot should be unnailed and washed every winter, and the walls thoroughly dressed with the Peach wall composition before they are nailed in again. The roots, too, should be treated precisely as we now treat those of Peaches whose new season commences as soon as the last fruit is gathered, and no one who wishes to succeed would think of allowing them to lie high and dry throughout the

autumn and winter. Under the false impression that the roots of fruit trees become dormant as soon as the leaves fall, many people think a dry border does no harm; but let them plant a Peach or Apricot, say in October, let them wash the soil well home, and they will find it has made a quantity of new roots by the end of November. Check these by drought and the work of bud feeding will come to a stand just when slow, but steady, progress is imperative.

OBITUARY.

MARSHALL P. WILDER.

AMERICA has lost one of her greatest and brightest horticulturists, viz., the Hon. Marshall Pinekey Wilder, who died at Boston, U.S., on December 17, in his eighty-ninth year. He was one of the oldest and most successful of Boston merchants. But trade and the acquisition of wealth had by no means been the all-engrossing aim of his life. His inherent love of rural pursuits led him, in 1832, to purchase an estate in Dorchester, where, after devoting a proper time to business, he gave his leisure hours to horticulture and agriculture. There he cultivated his own grounds, imported seeds, plants, and trees, and endeavoured by his example to encourage labour and elevate the rank of the gardener and husbandman. Here he prosecuted his favourite investigations, year after year, for at least half a century. Soon after the Massachusetts Horticultural Society was formed, Marshall Wilder became its president, an office which he held for eight years, and from that time till he died he was one of its most efficient members, constantly attending its meetings, taking part in its business and discussions, and contributing largely to its exhibitions. In 1879, on the occasion of its semi-centennial anniversary, he delivered an address (a copy of which is before us) alike remarkable for eloquence and ability. When he retired from the office of president, the society voted him a silver pitcher, valued at £30, and caused his portrait to be placed in its hall. As president he headed a circular for a convention of fruit growers, which was held in New York, October 10, 1848, when the American Pomological Society was formed—a grand association, to which we have no equal. He was chosen its first president, an office which he held for thirty-six years. Its biennial meetings, held in different places, are great occasions, on one of which, held in 1883, President Wilder, with his usual foresight, proposed a grand reform in the nomenclature of fruits for America, and asked the co-operation of other nations in this important matter. He said—

When we think of the irrelevant and inappropriate names by which many of our fruits are known, we feel the importance of keeping up our warfare until the victory is won, and our catalogues are purged of these improprieties. Long, superfluous, ostentatious, or unmeaning titles hitherto applied would be avoided in the future. Like the Baldwin Apple, the Bartlett Pear, the Concord Grape, and other renowned fruits, let such varieties be dedicated to perpetual remembrance by appropriate names, and thus let us hand down to future generations a system of nomenclature pure and plain in its diction, pertinent and proper in its application, and which shall be an example, not only for fruits, but for other products of the earth. Let us have no more names of generals, colonels, captains, presidents, governors, monarchs, kings or princes, mammoths or Tom Thumbs, or such titles as Nonsuch, Seek-no-further, Ne Plus Ultra, Hogpen, Sheepnose, Big Bob, Ironclad, Legal Tender, Sucker State, or Stump-the-World. The terms Pearmain, Pippin, Beurré, Doyenné, Bon Chrétien, &c., applied to Apples and Pears once described classes of fruit which are now so confused and blended that the names have lost their significance. The cases are

very few where a single word will not form a better name for a fruit than two or more. These reforms have been adopted in the catalogue of the American Pomological Society, and other prominent horticultural and pomological societies have voted to adopt improved nomenclature. It has been suggested that the work might be carried farther than has been done in the catalogue of the Pomological Society, as, for instance, by substituting *Lucrativa* for *Belle Lucrativa*, and *Nelis* for *Winter Nelis*. Pomologists may differ as to how far the reform should be carried, but by comparison of views they will come to a final agreement. I desire especially to enforce upon nurserymen the duty of aiding in this reform, by revising their catalogues so as to correspond with the improved nomenclature. Horticultural and pomological associations have thus far been our most powerful auxiliaries in this good work, but they do not come in contact with the people at so many points as the nurserymen whose catalogues are distributed broadcast. Let us push on the work so constantly and vigorously while we live, that future generations, seeing its advantages, shall avoid the evils we have encountered, and shall enjoy the benefits of the improved system, and look back with gratitude to us for our labours.

In February, 1849, the Norfolk Agricultural Society was formed, and Mr. Wilder was chosen president, an office which he held for twenty years; and as to other horticultural and agricultural societies with which he was connected, their name is legion. He was one of the commissioners appointed to the Universal Exposition in Paris, 1867, when he was placed at the head of the committee on horticulture and the cultivation and products of the Vine, the report of which was published by act of Congress. In short, his published speeches and writings amount to nearly one hundred in number, and Dartmouth College, as a testimonial to his services in science and literature, conferred upon him, in the year 1877, the degree of Doctor of Philosophy.

In all his pursuits and avocations, Mr. Wilder seems to have realised and practised that grand principle, which has such a bearing and influence on the whole course of life—the philosophy of habit. Part of his leisure hours he devoted to his pen, which has filled several large volumes with descriptions and delineations of fruits and flowers, proved under his own inspection. In a letter sent to us in July last he says:—

I am largely interested in the culture of the Pear and Strawberry. Of the former I have about 800 varieties, and at the late exhibition of the Horticultural Society, I placed on the table thirty varieties, or more than double that of any other exhibitor. My collection of Camellias and Azaleas is still large and choice, and I have many seedlings, such as Wilderi, Mrs. Abbie Wilder, and others well known in Europe for more than forty years. I still keep up my interest in cross-fertilisation of plants, and the proving of everything new and promising.

Marshall Wilder has, indeed, shown us by his life what an individual may accomplish by the concentration of one's intellectual powers on grand objects. He has been pre-eminent in the establishment and development of institutions. Few men have been called upon so often to preside over constituted societies, and few have acquitted themselves so happily in such positions. At a complimentary banquet given him in September, 1883, on his completing the age of eighty-five, Mr. Winthrop said—

No other man has done so much for our fields, gardens, and orchards as Marshall Wilder. He has also distinguished himself in many other lines of life, and his relations to the Legislature of Massachusetts and to the Historic Genealogical Society will not soon be forgotten. But his name will have its most enduring and most enviable association with flowers and fruits, for whose culture he was foremost in striving, both by precept and example. He deserves a grateful

remembrance as long as a fine Pear is relished or a brilliant bouquet admired.

Marshall Wilder was a foreign member of our Royal Horticultural Society, and on the occasion of his eighty-eighth birthday a congratulatory letter was despatched to him from the scientific committee.

KITCHEN GARDEN.

EARLY PEAS UNDER GLASS.

ONE of the best kinds of Peas, if not the best, for culture under glass is the American Wonder. Peas will not bear much artificial heat. As soon as they begin to run up, if the night temperature exceeds 50°, they become spindly and weakly. The seeds will germinate in a high temperature, of course, but anything partaking of the character of forcing, as commonly understood, does not produce satisfactory results. I have had very good early Peas in a pit in which there was just a little bottom-heat from a bed of leaves made up now. The leaves were made firm to prevent too great a settlement, and the pit was filled full enough to lift the Peas up near the glass. About 8 inches or 9 inches of soil were placed on the leaves. It was taken from an old Melon bed; and was consequently of good quality and in a healthy, mellow condition. Under such circumstances the Peas grew rapidly. They were properly sheltered at night, and daily ventilated when the weather was suitable. All Peas, whether dwarf or tall, under glass should be well supported with sticks. It does not answer to allow them to fall over and become entangled in their growth. A little dry, mellow soil should be placed in a ridge on each side of the rows as soon as they require support, and they should be staked whilst still in an erect position. Nothing is gained by sowing too thickly in the rows or by placing the rows too near each other. From 16 inches to 18 inches between the rows will be none too much space for the American Wonder and other dwarf varieties. Peas may be grown in pots equally easily as planted in a bed. They involve more labour, but all the care required is to keep them in a light position in a greenhouse temperature and to ventilate freely when not absolutely freezing. They succeed very well in 8-inch pots on shelves near the glass. They will do with only the protection of glass without artificial heat, but it is a great advantage to have enough warmth to keep out frost.

Peas if sown now in the open border, or as soon as the weather breaks, will not be much behind those planted in November, even if the latter escape injury from the late spell of cold weather. It is an advantage to lay the seeds in dry, mellow soil, and some effort should be made to obtain as much of the same material as will cover the seeds in situations where the soil of the border is wet and cold. Where there is room under glass Peas may be sown in 5-inch pots, and be transplanted in March when the weather has become suitable, sheltering them when first turned out with Evergreen branches. There are other expedients which may be adopted for raising Peas in heat for open-air planting later in the season when the weather is more

suitable. Peas raised under glass are not exposed to the same vicissitudes as when planted in the open air at this season, and as they transplant well, those having glass houses or warm pits will doubtless, acting on the principle of having two strings to their bow, plant a part of the first early crop in this manner. Sods of turf from 6 inches to 8 inches long, 4 inches wide, and 3 inches thick, with a groove hollowed out down the centre to receive the seeds, will do very well for raising Peas for turning out. The Peas are sown along the hollow, scooped out with a trowel and covered with light, rich soil. They may be placed in any house or pit in which there is just a little warmth, and when up an inch or so high they should be moved to a cold frame till the weather is suitable for planting them out. The sods of turf should be set in the drill without disturbing the Peas.

he might help us a bit; but there is scarcely a worse case of wasted energy than this eternal talk about new Potatoes. Soils have a great deal to do with Potatoes—everybody must know that—and it really should be a question for private growers whether they should grow Potatoes at all if their soil does not give them a good result. I myself have a stiffish soil and grow Potatoes, but they are inferior. Gilbert gave me some of his best, and he knows as well as anybody what good Potatoes are; but they are so inferior to the Regents of the London market, that I take down a bag of Regents with me, and leave the rest to the crows and pheasants. I fear all this talk about new Potatoes is not in the public interest, but in that of certain raisers and sellers of new varieties. —E. T. G.

RAISING CUCUMBERS, MELONS, AND TOMATOES.

Not a little depends upon the start made with these plants. I hold it indeed to be of the utmost importance that healthy, sturdy, and clean plants be always put out, and therefore I bestow rather more than ordinary pains upon their preparation. Drawn and weakly plants are frequently a long time in becoming sufficiently strong to perfect good crops, and it is certain that if plants infested with either thrips, red spider, or mealy bug are used, they will never be thoroughly clear of these pests. The old-fashioned plan of raising Cucumber and Melon plants in frames over a hotbed has still much to recommend it, as although it involves more trouble, the plants are much less liable to be infested by insects than those raised in a hothouse. If placed anywhere near the hot water pipes, red spider soon infests them, and even when raised on a hotbed in a forcing-house other plants are apt to infect them with green fly, or, worse still, black fly, bug, and thrips. As a rule, the first week in January is quite early enough to sow Cucumber and Melon seeds, though, for my part, I prefer the end of the month; there is then more light and sunshine, and the plants raised are much sturdier than those got up at an earlier date. For all ordinary purposes, a good strain of Telegraph is yet unsurpassed, and a good companion for it is Cardiff Castle. The latter is the smaller of the two, but it possesses a stronger constitution, is very prolific, and in quality it is excellent. Telegraph being wonderfully prolific is apt to be weakened by over cropping, but if the young Cucumbers were oftener freely thinned, undesirable gluts would be avoided, and the plants would remain cleaner and in better bearing order than is generally the case.

THE LATE MARSHALL P. WILDER.
Engraved for THE GARDEN.

Varieties of early Peas are now very numerous, but one need not plant many kinds in order to obtain an early supply to continue bearing till the second earlies and the main crop kinds come in. As a dwarf Pea there is nothing better than the American Wonder. Ringleader is one of the best of early white Peas, and William the First is a good kind to follow in succession. E. HOBDAV.

New Potatoes.—I have seen "A. D.'s" article on the best Potatoes, and I have read a great deal in THE GARDEN about them, and heard of Potato shows and all sorts of exhibitions devoted to this popular root; but surely it is the most futile fuss that can be made about anything, considering that not one of these new varieties equals in flavour the Regent of the London market. If "A. D." would mention the best half-dozen old or new Potatoes

MELONS.—For the earliest crops of these, whether to be obtained from plants in pots or on beds, there are none to surpass the true stock of Blenheim Orange. This usually sets well, ripens quickly, and though a scarlet-fleshed variety is excellent in quality. The good old Victory of Bath is still to be recommended for early crops, and is certainly to be preferred to a mongrel Eastnor Castle. If the latter can be obtained true, it is well worth growing; but who now-a-days has it uncrossed or undegenerated? Hero of Lockinge still keeps popular for either house or frame culture, and another very handsome green-fleshed sort will be found in Cox's Golden Gem. Longleaf Perfection requires special treatment; otherwise it is unprofitable. Owing to its high quality, many will, however, be tempted to cultivate it for the first time this season. From the

foregoing it will be seen that I am not much in favour of novelties; on the contrary, I prefer to grow sorts with which I am well acquainted, and which give satisfaction to those who eat them. After all, everything depends upon the way in which Melons are grown and ripened; it is possible to have nearly every known variety sufficiently good to gain approbation anywhere.

Incredible as it may appear, there are yet cultivators who sow the seeds of Cucumbers and Melons thickly in pots much in the same way as they would sow Mustard and Cress in a box. Plants thus raised are sure to be much drawn and weakly, and as the practice also necessitates shaking out and potting off singly, much valuable time is consumed in bringing these weakly subjects into a condition fit for planting out. The plan long adopted by us is to sow singly in clean 3-inch pots filled with rather light loamy soil; the seeds are buried about an inch below the surface, the thin end being uppermost. The pots are then plunged in a brisk bottom-heat either in a frame or forcing-house, in either of which the seeds germinate strongly and quickly. Little or no water is needed at the outset, especially if the heat of the bed is below 70°. If kept too moist the seeds will be liable to decay, especially early in the year. We do not dislike the seedlings being somewhat "long in the leg"; in fact, Melons with a good length of stem below the seed-leaves are much less liable to canker at the collar than if shorter. The hotbed being in a fairly light position, the young plants may remain plunged, thus encouraging brisk root action. At an early stage of growth each plant should be lightly staked, and when the rough leaf is well developed and the pot filled with roots the best of the plants, or rather more than will be eventually required, should be at once given a shift. For this purpose we use good loamy soil, thoroughly warmed, and clean 6-inch pots, and pot firmly. On no account should dirty pots be employed. If well attended to the young plants soon become established in the fresh soil, and should be finally transferred to their fruiting quarters before they become badly root-bound. No greater mistake can be made than unduly delaying the planting out, as when once the plants harden and branch out it is almost impossible to get them right again. From the first they ought to be kept steadily growing; it is even better to raise fresh plants than to depend upon stunted ones. While the plants are being prepared, the beds or pots, as the case may be, ought also to be got in readiness for their reception. Small bodies of soil are preferable at the commencement to accumulations of greater bulk. Small quantities are more easily warmed, remain in sweeter condition, and there is less danger of the bottom-heat being confined, and thereby seriously crippling the roots. Warm, fresh compost can be added at leisure, and Cucumbers and Melons, when growing strongly, soon take possession of it. One, or at the most two sowings are necessary in the case of Cucumbers—one at the present time to furnish plants to keep in fall bearing at least till midsummer, and another in May or early in June to provide plants for frames and pits. A long succession of Melons being required, four or five sowings in their case are necessary, or, say, in January, February, March, and April, allowing each batch of plants about four months in which to mature fruit. Much less trouble need be taken with the later sowings than with the earlier ones. The seed may be sown in $\frac{1}{2}$ inch pots and the plants put out when a good rough leaf is formed, but in every case they should be reared well away from old plants of the same sorts, as well as all kinds of stove plants, or the chances are that dirty plants will be the result.

TOMATO PLANTS also well repay any extra trouble that may be taken in raising them. Many prefer plants struck from cuttings to seedlings, and I have known good growers strike the tops of seedlings and throw away the bottoms, the idea being that they thus obtain dwarfer and more fruitful plants. This is, however, a fallacy, and the practice ought to find no favour, except it is only by means of cuttings that any particular

variety can be had. It is true that seedlings of many kinds of plants are much longer in attaining fruitfulness than cutting-raised plants, but the former are invariably the strongest. Seedling Tomatoes, however, may easily be had in a dwarf, fruitful state, and as far as my experience goes are always preferable to cutting-raised plants. The former may be raised clean or free from the troublesome little Aleyrodes that infest them, but it is frequently a very difficult matter to obtain clean cuttings. The Aleyrodes can never be thoroughly eradicated unless Tomatoes are cleared out for a time, and the house and all its other inmates subjected to a thorough cleansing. Hathaway's Excelsior, Large Red, Hackwood Park Prolific, Dedham Favourite, Reading Perfection, Dwarf Orangefield, and Carter's Perfection are all well adapted for pot and house culture. Large Red and Dwarf Orangefield, both corrugated sorts, set more freely than the rest and are also good in quality. For early supplies the seed should be sown now, thinly, in well-drained 8-inch pots filled with light soil. After being watered they may be plunged in a gentle hotbed, and a square of glass placed over each pot materially hastens germination. The glass should be removed soon after the seedlings break through the soil, and when the seed leaves are well unfolded the pots should be placed near the glass in the same house. If at all crowded they ought to be thinned out freely, the aim being to keep them sturdy from the commencement. When two leaves besides the seed leaves show themselves, the time has arrived for potting off, for which either 5-inch or 6-inch pots may be used—in the former place one plant, and in the latter two. Any good loamy soil will suit them, and this should be well warmed by plunging hot bricks in its midst prior to using it. The seedlings should be carefully shaken out of the soil and at once potted, this work being done in the house in which they are growing. One crock and a little rough soil constitute drainage sufficient for each pot, and the seedlings should be sunk up to their seed-leaves in the soil and lightly potted. If returned to a warm position, carefully watered and shaded from bright sunshine, plants thus treated soon commence growing afresh and emit roots from the whole length of the stems buried. Directly they seem to be recovered from the check thus sustained they ought to be transferred to a warm shelf near the glass, and if properly attended to will rapidly develop into fine, sturdy plants. Many succeed very well up to this point, but manage to spoil their plants afterwards from keeping them too long in the small pots. Directly they are root-bound the growth becomes spindly, and this should be anticipated by early transference to their fruiting quarters. Last season some of our first bunches of fruit nearly touched the soil, and nearly all commenced to fruit at about a foot from it. The plants were dwarf and sturdy when put out and were placed rather deeply in the pots, thus both further dwarfing them and admitting of a subsequent liberal top-dressing of loam and manure. For such sturdy plants stakes from 3 feet to 4 feet in length are quite long enough; all being grown with one stem (the side shoots being rubbed out as they appear) and heavily fruited, prove both ornamental and profitable. Those planted on mounds of soil and trained under the roof were equally profitable, most of them commencing to fruit long before the trellis was reached. Any plants not wanted for the earliest crops are best consigned to the rubbish heap. Where plants are required for cool structures, March is quite early enough to sow the seed.

Two favourable seasons in succession will give a stimulus to open-air culture, and more would succeed in less favourable years if more attention were paid to the proper preparation of the plants. Instead of sowing very early in March and according starvation treatment from the commencement, the end of March or early in April should be chosen, and the plants be kept steadily growing, either in warm frames or on shelves in a green-

house till near the time of planting out. If time and space can be spared, I would recommend that the seedlings be first potted singly into 5-inch pots, and when well rooted be shifted into 8-inch pots, good loamy soil and very little drainage being used in each instance. Then, if properly staked and given good room either in a light, airy greenhouse or pit, they will soon form a strong bunch of bloom; this will set and perhaps another not far behind it prior to planting out early in June. Then if they are given a warm position against a wall and fairly rich soil to grow in, a quantity of good fruit will ripen in July and August, or some time before the disease makes an appearance. Much starved plants lose their first and sometimes second bunch of bloom, and a late and uncertain crop is the result. W. I.

KITCHEN GARDEN NOTES.

W. WILDSMITH.

My contributions under this head will not be in the ordinary calendrical style, but they will be seasonable, *i. e.*, sowing, planting, or general cultivation, as the case may be, of whatever is under discussion, may begin when my notes appear. By thus omitting details, we shall have increased space to fully explain the cultivation, &c., of the various vegetables that may come under review; and further, to be practical, my observations shall consist of what we ourselves are doing at the time, or what is in immediate contemplation. With this introduction, I begin with

POTATOES.—Opinions may differ, but mine is that this is the most important of all vegetable crops. Others evidently think the same, for we have never yet been told to grow fewer Potatoes. The inquiry begins about the middle of April. When are you going to give us new Potatoes? and it is of almost daily repetition till a full supply is forthcoming, either from frames or warm borders. We are now preparing for these supplies by starting the sets in shallow boxes of leaf-soil. They are about half-buried in the leaf-soil, and as soon as roots have well laid hold of the mould, they are planted in frames, being disbudded to a couple of eyes as they are taken out of the boxes, and laid on trays ready for planting in drills, that are drawn a foot apart and 4 inches deep, and the sets are planted 9 inches apart in the row. I ought to have mentioned that the beds are made up with tree leaves (Oak and Beech principally), two-thirds of these to one-third of long stable litter. The heat from this mixture is never intense, and, as a rule, lasts the whole season without needing the renewal of linings. Larger proportions of litter give out a greater heat, but it is a spurt, and soon over, and new linings must be had recourse to to keep matters right. "Slow, but sure," is the best motto in forcing operations of every description. The best soil for frame-cultivation is roughish vegetable mould and light loam in about equal proportions. The siftings from under the potting-bench and the soil that has been emptied out of boxes that have contained bedding plants we reserve for the purpose, and after it has thus done duty twice over, there is sufficient vitality left by adding to it a sprinkling of bonedust or a few bushels of droppings to make it an excellent compost for the growing of ridge Cucumbers and Vegetable Marrows. The sets that are intended for planting on warm borders in the open air are still on shelves in the Potato house, but are laid out singly, that those disposed to sprout may develop strong sprouts. We shall put the first batch in boxes of leaf soil a fortnight hence; meantime the borders will be got ready—in fact are so, except levelling down, the soil having been left rough when trenched in the autumn. From close observation, I am persuaded that we do not exercise sufficient care in the application of manure for Potato crops. Indeed, I have very nearly attained to the conviction that we do wrong in manuring at all for that crop, and that it would be desirable to plant on ground that had been well manured for a former crop, such as Onions, Celery, or French Beans.

I say nothing as to produce under these conditions, but I have proved that it is but little inferior and that quality is largely advanced, whilst in a season when murrain was prevalent there were fewer bad tubers. The best manure for ordinarily good garden soil is leaf-soil, or well rotted stable manure, or both in mixture, and it should be well incorporated with the soil. Fresh, what I call raw, manure is only fit for very hungry soils, and even then I would hesitate to plant Potatoes on such ground unless the manure had been trenched in during the winter. Except bones and bone dust, I have little faith in the lasting qualities of artificial manures. Soot and wood ashes are most excellent fertilisers for Potatoes, and so is salt for dry, gravelly sandy land; this last we have used with excellent results, applying it as soon as the tubers were planted. I cannot say the quantity to a given space, and therefore perhaps the best way to convey an idea as to quantity used is to say that it was a thick sprinkling and done by hand. With regard to varieties for frame and earliest open-air supplies, there are none, taking all points into consideration, that excel the old Ashleaf types, but as first succession sorts to these, several kinds have of late years come to the front, which, whilst equal in quality to the Ashleaf, are a long way in advance in respect of productiveness. The best of these are First and Best, Early Regent, and perhaps Early Market.

PEAS.—For some years now we have discontinued the once general plan of sowing these in November or early in December, simply for the reason that the crop was never ready a day earlier than that from Peas sown early in February; very naturally, therefore, we resolved to give up the practice, and save ourselves several weeks of anxiety as to the parloinings of the seed by mice, or the pecking out of the points of the young shoots by birds. Our first sowing will very shortly be made in small pots, and be placed to germinate in a cool Peach house, and from there be transplanted to the open border about the end of February. They will be thickly screened from cutting winds by staking them at once, and by using a few Spruce or Laurel boughs along the bottoms of the sticks. The border for this early crop slopes to the south, and is well sheltered from the north and east, as it is from those quarters that during spring-time our garden suffers most. I need hardly say that ground for Peas cannot well be too rich or too deep, and manure of any kind can be used. The number of first early varieties is bewildering, and when all are said to be "the best," one feels somewhat diffident about mentioning any. I, however, risk the censure I may incur by first saying that dwarf varieties find no favour with me, solely because there is never a crop on them, at least not one worthy of that designation, even when the haulm is covered with pods. Sutton's Ring-leader and Veitch's Extra Early are very early good kinds, both being from a week to ten days earlier than Laxton's William the First, which, taking quality into account, is the best first early Pea that has yet come under my notice. There are at least a dozen of most excellent very early kinds, and out of so many there is no doubt that the experience of others may be altogether the opposite of mine.

TOMATOES.—We have just made our first sowing in 5-inch pots, and placed in a temperature of 65° Earliest of All and Hackwood Park Prolific. The rapidity with which Tomatoes have come to be regarded as indispensable is surprising; a very few years ago we were never asked for them; now it is impossible to grow too many, and very fortunately their cultivation is of the easiest description. Those now sown are intended for growing in pots in vinerias, Peach houses, or any warm place having an average temperature of about 60°. The seedlings will be potted off as soon as of sufficient size to handle, and be potted singly in small pots, and as the roots reach the sides of the pots they will be shifted into larger, the final size being 10-inch. Good loam, not too

heavy or broken up too finely, with a small quantity of bone-dust, is the compost they relish. Manure is not required till the plants are in full fruit and the roots are cramped in the pots; manure water is then of great assistance, and should be given on alternate days. A compost overlone with manure is apt to cause the plants to miss fruiting at the right time; growth is so strong, that the flowers fail to set, and will so continue till the growth gets a check through the roots getting pot-bound. This can and should be prevented by using soil containing little, if any, manure. Soon as the clusters of fruit are formed and swelling, all deformed ones should be pinched off to ensure size and space to aid the fruit to ripen on all sides alike, as well as for appearance sake.

THE CHRYSANTHEMUMS OF FIFTY YEARS AGO.

ONE of the earliest and most remarkable contributions on the general history of our now popular queen of autumn was that of Mr. Sabine, to be found in vol. v. of the Transactions of the London Horticultural Society, published in 1826, with coloured figures of some of the varieties, but the earliest figure seems to be that of Rheede, which was published as early as 1699, and presumably represents *C. indicum*, of which our present Pompon varieties are considered as the modern representatives. But the fact is that, supposing three specific wild types of the Chrysanthemum of China and Japan ever existed, which is doubtful, we can assure ourselves that cultivation has quite obliterated them in the garden of to-day. The seed from almost any one variety of Chrysanthemum is now-a-days found to yield us varieties of all kinds, forms, and colours—incurved, re-dexed, singles and doubles, with quilled or strap-shaped florets, or of the Pompon or Anemone groups, so that I think we may bid good-bye to the old specific names of *C. indicum*, *C. sinense*, and *C. japonicum*, which possess no real meaning in the gardens of our time. To find out the early history of the Chrysanthemum one would need a few years' residence in China and Japan, where it would be possible to consult the native books and drawings, and more especially to study the pictorial representations of this their national flower as it appears on porcelain and lacquer ware, or on old textile fabrics of many kinds. I am told there is a room in the Mikado's palace at Tokio which is entirely devoted to carvings and paintings of this favourite Japanese flower. As is well known, the Dutch were amongst the earliest traders to deal with the Japanese, and the Chrysanthemum is said to have been introduced to Holland long before it reached our English shores. To say nothing of Breynius (1689), both Kämpfer (1712) and Thunberg (1784) allude to the flower, and original drawings may linger unseen and forgotten in some of the libraries of Holland or of Spain. Haworth also wrote on the Chrysanthemum on or before the year 1833, and proposed a new arrangement of the then existing kinds, which is as follows:—

Ranunculus flowered.

YELLOW INDIAN (Hort. Trans., v. 4, p. 330, tab. 12, and v. 5, p. 346). Of short stature (in its group) with very late and double, but small, flowers; and forms, with the next, a distinct species.

WHITE INDIAN (Hort. Trans., v. 4, p. 347). Shorter than the preceding, with very late and similar, but white, flowers.

WABERATA YELLOW (Hort. Trans., v. 6, p. 344). Flowers very late, with the preceding, and of similar size, but has much more entire leaves, and larger flowers, which make it a distinct species.

SPANISH BROWN (Hort. Trans., v. 4, p. 488, and v. 5, p. 420). Of short firm stature, but rather early and beautiful flowers, the size of the preceding, and with smallish leaves a little more pinnatifid, and probably a distinct species.

BLUSH RANUNCULUS-FLOWERED (Hort. Trans., v. 6, p. 328). Of short firm stature, and incrimed early flower, of a bluish colour, and peculiar neatness of form. I think I have two variations of it.

SMALL DEEP YELLOW, PAIR'S SMALL YELLOW (Hort. Trans., v. 6, p. 327). Taller and weaker than the last, early and small-flowered, with small and blunt pinnately-lobate leaves. Perhaps it may be a distinct species from its small leaves and flowers.

SMALL DEEP YELLOW, SMALL WINDSOR YELLOW (Hort. Trans., v. 5, p. 415, and v. 6, p. 335). Also called 'Aitons' Yellow. Of short stiff growth, and early flowering, and but little merit.

SMALL FLAT YELLOW, SMALL YELLOW (Hort. Trans., v. 5, tab. 17, and v. 5, p. 422). Of shortish growth, and with pure yellow and expanded early flowers, the shape and size of the three subsequent varieties, of which it is presumed to be the origin, as yellow is the most predominant colour in these plants. Their forms are very neat and regular.

THE BUFF, or BUTTER (Hort. Trans., v. 5, p. 420). Also called the Orange, or Buff. Resembles the preceding in everything but colour.

THE ROSE, or PINK (Hort. Trans., v. 4, p. 344). Also called the Luteo. Resembles the last in all things but colour, and is now the most common kind in cultivation, although introduced after the old purple, hexamerid-emanate.

THE PALE PINK (Hort. Trans., v. 6, p. 336). Raised in Mr. Colvill's nursery, being a sportive branch from the last, and differing in nothing but colour. This and the three preceding doubtless sport mutually into each other, and are perpetuated by cuttings of their respective sports in the first instance, and offsets as well as cuttings afterwards, but are all liable to sport again, from pale pink through deeper pink, and copper or light orange to bright yellow; but their shoots and leaves are inimitable.

EXPANDED LIGHT PEARLE (Hort. Trans., v. 5, p. 153, and v. 5, p. 421; and Hort. Mag., tab. 2250). Of middling size, and with flowers in the middle season (of its group), but nearly twice as large as the last, though resembling it in form, and far more handsome.

QUILLED LIGHT PEARLE (Hort. Trans., v. 5, p. 155, and v. 5, p. 421). A sport only from the last, but now made permanent.

Incurving Ranunculus flowered.

INTERVING LIGHT (Sweet, Brit. Fl. Gard., tab. 7). Called LIGHT (Hort. Trans., v. 5, p. 155 and p. 421). Also called the Quilled Light. Grows tall, and flowers early, and is an elegant plant, allied to the preceding, and has produced the following one from a sportive branch.

QUILLED BLUSH (Hort. Trans., v. 6, p. 326). Has been called the Double Blush and Double White. The flowers, which are rather early, large, and showy, dying off nearly of that colour. It is of middling stature in its group; and, although a sport only of the preceding, is now an established and more beautiful variety than it.

THE QUILLED PINK (Hort. Trans., v. 4, p. 350, and v. 5, p. 351, 420, 421; and Hort. Reg., v. 8, tab. 919). Of tall stature, and one of the very latest in blooming; but very handsome, and repaying by its beauty every care bestowed upon it by the gardener. It has been called the most beautiful of all; but with me it yields to the Gold-bordered Red.

LARGE QUILLED ORANGE (Hort. Trans., v. 5, p. 152, tab. 3 copper figure, and v. 5, p. 421). A tall and large (dist.)-flowering variety, of considerable beauty, and at present uncommon.

GOLD-BORDERED RED (the TWO-COLOURED INCURVED OF Hort. Trans., v. 6, p. 32, 333). Of tall stature, very late, with the most perfect and beautiful flower of all its genus, although only of the middle size. The red petals are striped with gold beneath, and golden-tipped there; which tips, merging strongly and gracefully, show the gold in a front view of the flower, which is golden likewise at its base within. I consider it the most complete of all.

THE SUPERB WHITE (Hort. Trans., v. 4, p. 338, and v. 5, p. 190; Hort. Reg., pl. 479). A late, very tall, and splendid plant, with large, incurving, very double, pure white flowers.

China Aster flowered, often showing a disc, and then much resembling China Asters.

THE SULPHUR YELLOW (Hort. Trans., v. 4, p. 341, and v. 5, p. 420). A beautiful variety, of tall stature, and free and early blooming, with middle-sized Aster-like flowers.

THE TWO-COLOURED RED (Hort. Trans., v. 6, tab. 4, and v. 6, p. 342, 343). A very fine and showy variety, of the middle size in stem and flowers, but rather late, which sometimes shows a disc, and is then very Aster-like. The bipinnatifid leaves are far more limited than any other kind; and I think they constitute it a distinct species.

THE EARLY CRIMSON (Hort. Trans., v. 5, tab. 5 (inferior figure), p. 151 and p. 421). Of light, small stature, delicate, and apt to lose its leaves before its bloom is finished. The flowers are middle-sized, early, and very beautiful; they show a disc, and when well managed, have ripened perfect seeds in England.

THE CLUSTERED PINK (Hort. Trans., v. 6, p. 336). Also known by the name of the Changeable Blue. One of the tallest of its tribe; flowers in the middle season very abundantly; and, although the flowers are but middle-sized, and little better than half-double, showing a considerable disc, and greatly resemble China Asters, they make a very fine and durable appearance, standing the weather well, and becoming much darker by age, though less delicate. This is a very likely variety to produce seed in this country.

THE EARLY BLUSH (Hort. Trans., v. 6, p. 326). This tall and almost unimpeded variety is also called the Double Blush and Double White. It flowers very early, beautifully, and freely, and its flowers are large, and scarcely show any disc; and their colour without is light blush, but within they are exactly of the peculiar tint well known by the name of French white; and, like many other varieties, they are very durable. They have ripened seeds in England.

THE PALE WHITE (Hort. Trans., v. 5, p. 417, 422). This exquisitely white-flowering and noble variety is of tall stature, and early blooming, and makes a splendid appearance in a general collection. Its flowers are of the middle size.

Marigold-flowered: with well formed double flowers resembling Double Cape Marigolds in shape and size.

GOLDEN BRONZE-BACK, GOLDEN YELLOW (Hort. Trans., v. 6, p. 342; and Bot. Reg., tab. 4 (superior figure)). Also called the Large Yellow and the King's Yellow. A very tall, handsome, and free-flowering variety. The flowers are early, and of a high rich yellow colour, but bronzed or orange in the buds and on the outsides. This is one of the best to grow as a standard; and, if parted at the root and annually transplanted, succeeds very well as a herbaceous plant, especially if in a warm or sheltered situation, duly supported by a stick.

THE SUPERB CLUSTERED YELLOW (Hort. Trans., v. 5, p. 156, and v. 5, p. 421; and Sweet's Brit. Fl. Gard., tab. 14). One of the finest and tallest of the group, being higher than the preceding, and with more clustered, and more neatly formed, pure yellow flowers, but they are later in opening.

THE GOLDEN LOTUS-FLOWERED (Hort. Trans., v. 6, p. 340). A very splendid and large long-leaved variety, and nearly or quite the tallest of this genus of plants; having late pure and deep yellow flowers, above the middle size, and larger than those of any other yellow kind of the Marigold form, and which partly endure until the heavier frosts of winter destroy them.

THE CHANGEABLE PALE BUFF (Hort. Trans., v. 6, p. 380, and tab. 3). Also called the Pale Cluster. This plant, when flowering as perfectly as it is represented on the above-cited table, is one of the most showy and splendid in the group; but this has not been the case during the autumn of 1832; all the flowers, and in various gardens, which met the writer's eye, being, as it were, degenerated into almost buff-coloured and spuriously quilled flowers, of more upright appearance than the large, expanded, flat-petalled, and variegated purple whitish and yellow-buff ones so charmingly depicted in the figure cited. They are of the middle season.

STARRY CHANGEABLE PURPLE, THE STARRY PURPLE (Hort. Trans., v. 6, p. 339). This beautiful plant is one of the most variable-flowered in the genus, its very late flowers first opening of a purple colour, with the exterior petals at first few in number, starry, and paler, especially at their expanded spoon-shaped tips, soon, however, becoming still more pale until the whole well-expanded and very double blossom becomes regularly more bluish coloured and white than purple, and is a very fine, well-formed, variegated flower. The stature of the plant is of the middle size, but its remarkable leaves are much more laminated than usual, and often broader in their outline than long, which is not the case with any other in the group, and of very considerable size. Wherefore I conceive it may be a distinct species from all the others.

THE LATE PURPLE, THE LATE PALE PURPLE (Hort. Trans., v. 5, p. 413, and v. 5, p. 422, and v. 6, p. 353). Also called Large Pale Purple. This is a very late-flowering and rather tall variety, whose middling-sized and well-expanded blossoms are very neat, and resemble in shape those of the preceding, but are much smaller.

THE BROWN PURPLE (Hort. Trans., v. 6, p. 341-2). A tall and slender-twigged very late-flowering variety, whose middle-sized flowers resemble the last in shape, but are not quite so flat and neat in expansion, and their colour in the group is very remarkable, being of a very dull brownish or reddish purple. The leaves are so small, and so bluntly lobed and on such slender shoots, terminating in such long and graceful peduncles, that the plant is probably a distinct species from *Chrysanthemum sinense*, and differs not so much in leaf as in flower from the Small Deep Yellow above.

Tassel-flowered: being tall or very tall plants in their genus, with very large double, and more or less conspicuously drooping flowers, whose petals are usually elongated and quilled, and often greatly resemble the form of a tassel.

THE TASSELED FLAME YELLOW, THE QUILLED FLAME YELLOW (Hort. Trans., v. 4, tab. 14, p. 341, and v. 5, p. 421). The magnificent flowers of this tall plant appear rather late, and often measure above 5 inches in expansion, and make, perhaps, if not a more neat, at least a more showy appearance than any other of the group, being double, and composed of innumerable chiefly quilled incurving petals, hanging more or less downwards, and when at their best resembling a flame-coloured tassel.

THE TASSELED SALMON, THE QUILLED SALMON (Hort. Trans., v. 5, tab. 17 (inferior figure), p. 414, and p. 422). This is a late-flowering, slender, and graceful plant, with large tassel-like and half-expanded drooping quilled salmon-coloured flowers, and is very uncommon.

THE TASSELED YELLOW (Hort. Trans., v. 6, p. 329). A very tall and strong-growing, large-leaved variety, with numerous tassel-formed flowers of the largest and most showy kind, often measuring more than 5 inches over, and appearing rather early. It is one of the most desirable and free-growing of the whole collection.

THE QUILLED YELLOW (Hort. Trans., v. 4, p. 341, and v. 5, p. 420). This is a tall variety, with rather large flowers, of the middle season, or later, producing its blossoms in clusters at the top of the strong upright shoots. It is also known by the name of the Quilled Straw.

THE LATE QUILLED YELLOW (Hort. Trans., v. 6, p. 343). This has been called a very late and not very desirable variety in collections. It appears to be of the middle size, but it has not yet opened its blossom-buds with me, not having long possessed it.

THE LARGE LILAC (Hort. Trans., v. 4, p. 343, and v. 5, p. 420). Also called the Late Lilac, the New Lilac, and the Semi-double Purple. A very tall, upright plant, bearing but few double large and clustered flowers at the summits of the branches, and those so late in appearance, that in cold seasons they cannot expand well, and are consequently in but little repute. I have only seen one plant in blossom, and that in my own garden.

THE TASSELED LILAC (Hort. Trans., v. 6, p. 332). A middle-sized, or rather tall, plant of very great beauty, and one of the most desirable of the whole group, having very showy tassel-formed flowers, 5 inches or more in expansion, very numerous, early, and elegantly drooping from their weight, but they often show a disc. It is a likely variety to produce seeds of the most promising kind, but I have not hitherto heard of its ripening any in England.

THE TASSELED PURPLE, THE PURPLE (Hort. Trans., v. 4, p. 334). Has also been called the Old Purple, the Old Red, and the Quilled Purple, and is figured in the Bot. Mag. (tab. 327). This is a very beautiful and rather early-flowering plant of almost the middle size. The flowers are very numerous, gracefully drooping, and of middling size, and are at first of a reddish purple colour, but become paler by age, and in mild seasons will continue in succession from the end of October to the second week in January. It acquires the name of Old from being the first China *Chrysanthemum* that came to England in modern times, and bloomed in Mr. Colvill's nursery in November, 1795, but was said to be at Kew in 1790. The great horticulturist Miller certainly had one, or more likely two, of these Chinese, or Indian, *Chrysanthemums* in cultivation at Chelsea long before; but it is not yet quite satisfactorily explained what sorts they were. See Hort. Trans., v. 4, tab. 12, p. 228, and following.

THE CHANGEABLE TASSELED WHITE, THE CHANGEABLE WHITE (Hort. Trans., v. 4, p. 336, and v. 5, p. 419; and Bot. Mag., tab. 2042). It has also been called the Old White, being the first white flowered variety known in our gardens. It is recorded in the Hort. Trans. to have been raised from a sporting branch of the preceding, and, indeed, resembles it in everything but colour. It is a very graceful and elegant plant, and in warm situations its flowers are often more or less tinged or dotted with purple or bluish colour.

Fig. 1, the common centipede (*Lithobius forficatus*); 2, numerous ditto (*Geophilus longicornis*); 3, underside of head of centipede, showing the mouth organs (magnified).

THE NARROW QUILLED WHITE, THE QUILLED WHITE (Hort. Trans., v. 4, p. 337, and v. 5, p. 419). This rather slender variety is almost of the middle size, and has the slenderest and most completely quilled florets, and the earliest flowers of the whole group, which hang in gracefully drooping tassels, and form a strong contrast to the next in almost every respect.

THE GREAT TASSELED WHITE, THE TASSELED WHITE (Hort. Trans., v. 1, p. 339, and v. 5, p. 420). Has also been called the Expanded White. This large, strong and broad, deep-green shining-leaved variety is one of the latest of all in blooming, but its lovely flowers are larger and more showy than those of any white-flowered variety, and endured to the end of January, 1833, the date of the present paper. No flower in this chilly climate stands the cold so well, or so long continues to beguile the fancy of a florist by its protracted opening, by its hardihood in expansion, and by the soft hue of its snowy blossoms, carrying on, as it were, the flowery beauty of lingering autumn into the very bosom of winter, whose ice at length closes the temple of Flora for a time, until the herald flowers of spring appear amidst the melting snow, as if impatient of delay.

Half-double. Tassel-flowered: with only half-double flowers, and narrow elongated, quilled petals; often drooping, and somewhat resembling a tassel.

HALF-DOUBLE QUILLED WHITE, SEMI-DOUBLE QUILLED WHITE (Hort. Trans., v. 5, p. 158). A very tall, robust variety. The flowers are among the latest varieties, and more inclining to be single than usual, yet of too late occurrence

to ripen seeds with us. They are very large, and the narrow quilled petals are very singularly waved, and as if pursuing each other from right to left, making a pleasing and almost animated appearance.

HALF-DOUBLE QUILLED PINK, SEMI-DOUBLE QUILLED PINK (Hort. Trans., v. 5, tab. 17 (inferior figure), p. 157, and v. 5, p. 422, and v. 6, p. 351). This variety grows rather tall and flowers bluish, but its flowers, although but half-double, and only of the middle size, possess a degree of graceful elegance and lovely hues peculiarly their own. It is at present a rare variety.

HALF-DOUBLE BRONZE BUFF, PALE BUFF (Hort. Trans., v. 6, p. 334). Also called the Semi-double Pale Buff, and Reeve's Pale Buff, and Quilled Buff, and the Buff. It is a very tall and free-growing variety, and its half-double buff large flowers, which in their early stages are much bronzed, though of course hues, make a showy appearance, and stand the weather better than all others, opening rather early, and continuing late, until all the bronze is gone, having faded to a dull buff.

HALF-DOUBLE QUILLED ORANGE, SEMI-DOUBLE QUILLED ORANGE (Hort. Trans., v. 5, p. 412 and p. 422, and v. 5, tab. 17 (left-hand figure), and v. 6, p. 352). A tallish plant, with but few large and almost single, and also some nearly half-double, flowers, of good size, but making a poor show.

HALF-DOUBLE PALE QUILLED ORANGE, SEMI-DOUBLE QUILLED PALE ORANGE (Hort. Trans., v. 6, p. 337). Also called Semi-double Deep Yellow. Of the middle stature, with few and late flowers, of good size, but comparatively poor appearance, on loosely drooping footstalks.

F. W. B.

GARDEN DESTROYERS.

CENTIPEDES.

THESE well-known creatures are not encouraged and protected as they deserve to be; on the contrary, most persons look on them with great dislike and horror. This, no doubt, is owing to the fact that they usually move very rapidly. Slugs, snails, caterpillars, and other creatures which are slow in their movements, persons do not shudder or shrink from so readily; but a spider, blackbeetle, an earwig, or a centipede are generally objects of great aversion. The account often given of the venomous nature of the bites of the large tropical species of centipedes, no doubt is an additional reason to regard these useful creatures with disgust. Useful they most certainly are, for they live almost (if not quite) entirely on animal food, such as insects, worms, &c. Centipedes usually feed at night time, and during the day hide themselves under stones, brick-bats, pieces of wood, rubbish, &c., or in crevices of the earth. The common centipede (*Lithobius forficatus*), fig. 1, is undoubtedly carnivorous; their active movements and the formation of their mouths, provided as they are with a powerful pair of poison fangs, point to their being creatures which prey upon living things, even if we had nothing else to guide us. There is, however, another very common centipede, the luminous centipede (*Geophilus longicornis*), fig. 2, which has been found under circumstances which seem to show that it does not at all times confine its diet strictly to animal food, although the organs of its mouth are formed in just the same manner as those of the other species; it is, however, a much more sluggish creature, and would be quite incapable of catching any tolerably active insect, for in spite of its great number of legs it moves very slowly, and with much deliberation, and it is quite probable that if when near the roots of plants, the supply of its ordinary food were to fall short, it would feed on them. This, and some other nearly allied species, seem to form a link between the Julidae (or snake millipedes), which are undoubtedly vegetarians, and those centipedes which are decidedly carnivorous. If it is suspected that they are injuring the roots of a plant, they may easily be found by turning up the earth round the plant, as their length (2½ inches) and pale colour render them very easy of detection; but though these creatures are common, they are seldom so abundant as to be the cause of much injury to plants. When near plants they are generally found in the company of snake millipedes, and like them they are protected by such a hardened skin that few, if any,

insecticides would reach them with fatal effect, unless they were very near the surface. Watering with brine has been recommended as a means of killing the snake millipedes, and would be worth trying in the case of these centipedes.

The centipedes belong to the same class (the Myriapoda) as the snake millipedes. They differ from them, however, in various particulars, but chiefly in the formation of their mouths; the latter are not provided with the powerful poison fangs (fig. 3) which are so conspicuous in the former. When the head is examined, another difference which may be easily recognised is that the snake millipedes have two pairs of legs attached to each joint of their bodies, while the centipedes have only one. All the snake millipedes crawl very slowly, but many centipedes are very quick in their movements. I have figured two of our commonest species, *Lithobius forficatus* (fig. 1) and *Geophilus longicornis* (fig. 2). The former species is, as I have already mentioned, undoubtedly carnivorous. It measures about an inch in length, not including the legs and antennæ; the latter consist of about forty joints; the legs have seven joints, and terminate in a single claw. The front pair of legs have become modified in form, and now serve as a pair of mandibles, terminating in poison fangs. Fig. 3 shows these fangs, in each of which is a poison gland, from which the poison is ejected through an aperture at the point of the fang. The points of the mandibles in the drawing touch the maxillæ or jaws, which are furnished at their edges where they meet with sharp teeth. Below these jaws is the under lip or labium, which is toothed along the upper edge. This lip appears as if divided longitudinally into two, and in young specimens it is really in two parts, but in full-grown specimens the two halves grow together and form one organ. Above the points of the mandibles is the upper lip. The eyes are situated just below the antennæ; the whole of the latter are not shown. The luminous centipede (*Geophilus longicornis*), fig. 2, is a remarkably long, narrow creature, measuring when fully grown about 2½ inches in length and not more than 1-20th of an inch in width. Its body is composed of a great number of joints, each of which is provided with a pair of legs. The last pair in the males are considerably longer than the others, and have very much the appearance of antennæ. The organs of the head are just the same as those of the common centipede. These creatures move in a slow, tortuous manner, and seem to glide along rather than walk; their legs are so small that they are scarcely observed.

At certain times, generally in the spring and autumn, supposed to be the breeding seasons, these centipedes emit a phosphorescent light, and they often leave an illuminated trail behind them some few inches, and occasionally 2 feet and even 3 feet, in length when they move about. Persons are often surprised to see a streak of phosphorescent light on a pathway, and wonder what can be the cause, for unless careful search be made, the author will not be noticed. The female lays her eggs, numbering nearly fifty, together in a cluster in a cell, which she forms in the earth. In this cell she remains coiled around the eggs until they are hatched, the period of incubation occupying a fortnight or three weeks. The centipedes hibernate during the winter.

G. S. S.

Beetles (*I. J. II.*)—The specimens you send are those of the common Vine weevil (*Othiorhynchus sulcatus*), a most destructive pest in all its stages. The beetles hide themselves during the day, and feed upon the leaves of almost any plants that come in their way at night. The best method of catching them is to place a white cloth or paper under the plants which they attack, then enter the house after dark with a light; this, usually causes them to drop

upon the cloth, when they may be gathered up and destroyed. The plants should be slightly tapped in order to bring down any which may be secreting themselves amongst the leaves.

SOCIETIES AND EXHIBITIONS.

ROYAL HORTICULTURAL.

JANUARY 11.

THIS, the first meeting of the year, opened with a bright display—far brighter than had been expected in such wintry weather as that which we are now having. The great feature of the meeting was an extensive and magnificent collection of new double and single Chinese Primulas, shown by Messrs. Sutton, of Reading, who seem to have made great strides in the improvement of these beautiful winter flowers. This was such an exceptional display, that it is worthy of notice beyond the report, and a detailed account of the sorts shown will be found in another column. The rest was a miscellaneous gathering of winter flowers, most of which were submitted to the committee, and these included not a few choice Orchids. The following plants were awarded first-class certificates:—

LÆLIA ANCEPS STELLA.—A splendid variety; the largest flowered of the numerous forms of this ever-popular Orchid. The flowers are a third larger than those of the ordinary form; the sepals and petals are pure white, and the large labellum is white also, adorned with a golden crest and very rich pencillings of plum-purple in its interior. This variety is second only to the lovely *Dawsoni*, but is fortunately not so rare. Some cut spikes of it were shown by Mr. Ballantine, gardener to Baron Schroeder, The Dell, Egham.

LÆLIA ANCEPS SANDERIANA.—This variety may be best compared with *Dawsoni*, that being the form it most nearly resembles, though inferior to it in every respect. The sepals are white, but not so snowy white as those of *Dawsoni* and not so broad; the petals, too, are narrow. The lip is of much the same form as *Dawsoni*, but the colouring is not so heavy nor so beautiful. It is, however, a good substitute for *Dawsoni*. A well-grown specimen, carrying two flower-spikes each with four flowers, was shown by Mr. Hill, Arnott's Hill, Notts; and some cut spikes were shown by Baron Schroeder, and to both exhibitors first-class certificates were awarded.

KOROLKOWIA DISCOLOR.—An ugly name for an unlovely plant, which is scarcely showier than its relative, *K. Suwarowi*, which has been grown in gardens a long time. It is like a *Fritillaria*, of dwarf growth, not more than 6 inches high, and with broad, glaucous-green leaves. The flowers are bell-shaped, about an inch across, produced from the axils of the leaves, and of a sort of bronzy yellow. It is said to be hardy, but the plant shown had evidently not been grown in the open air. It may be considered interesting, but is scarcely a good garden plant. It was shown by Mr. Ware, Hale Farm Nursery, Tottenham.

KALANCHOE CARNEA.—A pretty South African Crassulaceous plant, nearly allied to the common scarlet *Kalosanthes*, which it nearly resembles in the size and form of the flowers, and the way they are borne in dense clusters. The flowers are of a delicate pink, and sweetly scented like honey. Its natural flowering season is January and February, and it may be grown in a greenhouse; therefore it is a valuable winter plant, and one that will be, no doubt, much appreciated. Some cut trusses of bloom were shown by Messrs. Veitch, of Chelsea.

PTERIS TREMULA FLACCIDA.—A most elegant variety of a well-known and popular greenhouse Fern. The fronds of it, though not really crested, have that appearance, the pinnae being much wavy and of a cheerful green. A well-grown plant has widely-spreading fronds, and has a very graceful appearance. A fine specimen of it was shown by Mr. H. B. May, of Edmonton, with whom it originated, and who, no doubt, will find it invaluable as a market plant.

BARKERIA VANNERIANA.—A new and very beautiful Mexican Orchid, perhaps the finest of all the *Barkerias*, lovely though the others are. It is most like *B. elegans*, as it possesses the same graceful habit

of growth. The flower-spikes are slender, from 2 feet to 3 feet long, terminated by a dense cluster of flowers. These have narrow sepals and petals, and rounded oblong lips. The colour is a bright rosy purple, varied only by a white spot on the lip, and margined by a zone of deep carmine. Exhibited by Mr. Vanner, Camden Wood, Chislehurst, after whom the species was named not long since by Professor Reichenbach.

CYPRIPEDIUM LEEANUM SUPERBUM.—One of the finest of all the hybrid *Lady's Slipper* Orchids and greatly superior to the original *C. Leeanum*, which was also the result of intercrossing *C. Spicerianum* and *C. insigne*. The beauty of these two handsome species is continued in the hybrid in a striking way. The flowers are nearly as large as those of *insigne*, and the colour of the lateral sepals and pouch is much the same as that of *insigne*, but the upper or dorsal sepal is like that of *Spicerianum*, but much finer, being over 2 inches broad, pure white, adorned with numerous minute spots of purple. Flowers representing the best variety yet seen of this hybrid were shown by Mr. Ballantine, from Baron Schroeder's garden.

CHRYSANTHEMUM GOLDEN GEM.—A first-rate new late-flowering variety belonging to what is vaguely termed the decorative class. The flowers are of medium size, loose, as in other Japanese sorts, and produced in heads of five and six, so that it may be considered a free flowerer. The colour is a warm yellow, deepening towards the centre into a rich apricot tint, and this variation of colour adds greatly to the beauty of the flower. Flowers of it were shown by Mr. R. Owen, Floral Nurseries, Maidenhead.

CHRYSANTHEMUM MRS. H. JONES.—A clear canary-yellow sport from the well-known white, late-flowering Japanese variety *Ethel*. The flower of the sport is the counterpart of the original, and the colour is most pleasing. Being so late, it will be of great value for cut blooms. The variety has been in bloom since the first week in December. Some cut blooms of it were shown by Mr. Ware, of Tottenham.

PRIMULA SINENSIS FILICIFOLIA DOUBLE BLUE.—A beautiful and very distinct, new, double-flowered Chinese Primula with Fern-like foliage and double flowers of a rich purplish blue colour. Exhibited by Messrs. Sutton, Reading.

PRIMULA ROSY QUEEN.—A single-flowered sort with great trusses of large and perfectly shaped flowers of the loveliest colour imaginable, it being a kind of blush-pink shaded at the edges with white. This was the queen of a large collection shown by Messrs. Sutton.

PRIMULA DOUBLE SCARLET.—A sturdy and compact-growing sort with dense trusses of double flowers scarcely over-topping the foliage and of a brilliant carmine-crimson. From Messrs. Sutton.

PRIMULA DOUBLE BLUE.—The counterpart of the double blue Fern-leaved, except that the leaves are of the ordinary form and not as in the *filicifolia* variety; the leaf-stalks are of a conspicuous reddish brown. Exhibited by Messrs. Sutton.

PRIMULA DOUBLE ROSE.—Flowers very double, numerous, produced in compact trusses, and of a delicate rose-pink colour. One of the best doubles in Messrs. Sutton's collection.

PRIMULA GIPSY QUEEN.—A single-flowered variety with large white flowers, which contrast beautifully with the dark green foliage and ruddy tinged stalks. Exhibited by Messrs. Sutton.

Among the other exhibits the following were the most noteworthy. The Orchids from Baron Schroeder's garden were the centre of attraction, as among them were several not often seen in bloom. There were no fewer than six distinct varieties of *Lælia anceps*, including the rare *Dawsoni*, which is the queen of the series. There were spikes of this with three and four flowers. Then there were *Stella* and *Sanderiana*, both certificated; *Percivaliana*, a pretty tinted form; the true pure white *alba*, whose flowers have no trace of colour, except a dash of yellow on the lip; *Williamsi*, another white form, but marked with lines in the interior of the labellum; and, lastly, *Barkeri*, an old variety still unsurpassed for richness and depth

of colour. Besides the *Laelias*, Baron Schroeder showed some fine spikes of *Cattleya Percivaliana* *superba*, a variety justly worthy of the name on account of the huge size of the flower and splendour of its colour. Another rarity was *Laelia triophthalma*, one of the Veitchian hybrids, having *C. superba* for one of its parents. It is a distinct and brightly-coloured flower, as large as that of *L. elegans*, the distinct point about it being its round-lobed labellum. Mr. Pollett, of Fernside, Bickley, showed a spike of *Oncidium brevifolium*, a species rarely seen in bloom. It is a near ally of *O. coronarium*, and, like it, bears a cylindrical spike of flowers, which are as large as those of *O. crispum*, and of similar colour, a sort of reddish orange with bright yellow lip. Mr. Tantz, Studley House, Hammersmith, showed a new hybrid *Cypripedium*, named *Marshallianum*, which, however, is not a great beauty. It looks like a cross between *C. concolor* and *C. venustum*, both of which species we consider finer than the hybrid. Mr. Hill, of Nottingham, showed a new *Odontoglossum*, called *Arnottense*; it looks very much like *Coradinei*, if it is not that species. M. Vervae, of Ghent, sent two good spotted varieties of *Odontoglossum crispum* and a pretty little *Restrepia*, like *R. elegans*, but with striped instead of spotted flowers; therefore considered new. Various new sorts of Chinese *Primulas* were shown besides those from Messrs. Sutton. Two pretty sorts came from Messrs. Cannell, of Swanley, both singles, one with blush-pink flowers, the other of an intensely deep carmine. Mr. James Woodside, Farnham Royal, had a few new sorts, those named *Mary James*, a purplish mauve, and a good white, named *Advance*, being the best. Mr. R. Clarke, of Twickenham, sent some new seedling *Cyclamens*. Two of these were placed before the committee, but it was considered inexpedient to certificate individual plants of seedling *Cyclamens*, and, therefore, the strain only was commended. The *Cyclamens* included a very fine pure white and an intensely deep crimson named *Albert Victor*, certificated three or four years ago. Mr. Ware, of Tottenham, sent an interesting group, including *Christmas Roses*, very fine plants, the white Algerian *Narcissus monophyllus*, *Laehenalia pendula*, with bright red flowers, the little yellow *Primula floribunda*, which seems to flower throughout the winter, and *Freesia refracta alba*, whose snow-white flowers, deliciously fragrant, are invaluable for cutting at this season. A large group of the white *Erica byemalis*, from Mr. Kinghorn, showed what a beautiful plant this white *Heath* is at this season.

Fruit and vegetables.—Among the few exhibits put before the committee were two monster *Smooth Cayenne Pines*, from Mr. Roberts, gardener at Gunnersbury Park, to whom a cultural commendation was accorded. A new Grape, named *White Gros Colmar*, was shown by Mr. Roberts, Charleville Forest, Tullamore. Though called *White Gros Colmar*, the new sort does not bear a great resemblance to that variety, for, though the berries are round, they are not so large, neither are the bunches of the two identical in form. The colour is too green to be nice-looking, and the flavour is not first-rate. The committee desire to see this variety again. Mr. Norman, gardener at Hatfield House, was accorded a cultural commendation for a fine basket of *Mushrooms*, and the same award was voted to General Hutt's gardener, Appley Towers, Isle of Wight, for a dish of very fine fruits of *Diospyros Kaki*, gathered from a tree grown against a wall in an orchard house. The fruits are like large *Acme Tomatoes*, and of a bright orange colour. Some seedling *Apples* were shown, including a seedling from *Cornish Gilliflower*, shown by Mr. William Paul. Messrs. Wrench showed examples of *Curled Broccolo* or *Kale*, which is considered an excellent winter green.

NATIONAL CHRYSANTHEMUM MID-WINTER SHOW.

JANUARY 12 AND 13.

THERE is exceptional interest attached to a January show of *Chrysanthemums*, and the National Society acted wisely in making the experiment of holding a show so late in the season. That a *Chrysanthemum* show in the second week of January is possible was amply proved by the really excellent and large gather-

ing which was brought together from various parts of the country in the Royal Aquarium this week. It was larger by far than was expected, and the quality on the whole was excellent. True, there were many flowers shown which were out of season, or, in gardeners' language, "stale;" but, on the other hand, the show brought to light numerous little-known varieties, which because flowering so late naturally do not find a place at the November shows. One of the chief objects of this society in holding this late show is to encourage growers to treat their plants specially for the production of late bloom, and further to encourage raisers of new sorts to turn their attention to swelling the now meagre list of really good late kinds. As the matter stands now the grower is most successful at a late exhibition who possesses the best means of preserving his blooms, and it was surprising how successfully this had been done by several exhibitors at this Aquarium show. No doubt some had made special provision for this one show, but they must also have well considered their selection of sorts, for only a few can be kept in bloom so long. It needed only a glance at the table to see which class was most represented. There were scarcely any of the old-fashioned incurved sorts, only a few of the *Anemone*-flowered section, the bulk being of *Japanese* kinds, which are undoubtedly the best for preserving in bloom. The best dozen sorts, taking the show through and reckoning only those that looked as if they were still in season, would include *Ceres*, *Meg Merrilies*, *Jupiter*, *Ethel*, *Pelican*, *Mrs. C. Carey*, *Yellow Dragon*, *Mdme. Lacroix*, *Duchess of Albany*, *Boule d'Or*, *Mrs. Jones*, and *Golden Gem*. The two last named were unquestionably the best in the show, and stood out conspicuously from all the rest, and the raiser who can give similarly fine late sorts will be rewarded. We give the names of the chief sorts in the collection shown, as some readers may like to see which sorts are capable of holding out so long.

Mr. R. Owen showed the finest collection in the chief class, that for the best stand of blooms. He had a very numerous selection of sorts, the finest among them being *Meg Merrilies*, *Exposition de Chalou*, *Mdme. Anna DeLaux*, *Engène Mizard*, deep purple; *La France*, deep purple; *Mrs. Charles Carey*, single white; *Mons. Raoux*, pink; *Snowdrift*, white; *Tintamarre*, *Caprice*, yellow; *Yellow Dragon*, *Zaire*, bronze reflexed; *Comtesse de Beauregard*, *Reduplicata*, carmine-purple; *Pelican*, white; *Diana Vernon*, purple; *Nuit d'Atomme*, *Mdme. Deville*, *Ceres*, flesh; *Jupiter*, reddish orange; *Géante de Valence*, pale pink; *Mons. de Brazza*, *M. Maxime Cornu*, purple reflexed; *Virginale*, large white *Anemone*-flowered; *Belle Paule*, *Bush*; *Moonlight*, white; and *Golden Gem*, the beautiful new sort.

Mr. Bolas, Hopton House, Wirksworth, showed the second best collection. He had good blooms of *Mons. Paul Fabre*, red-chestnut; *Fleur de Marie*, *Cœur Fidele*, white; *F. A. Davis*, deep red; *Mdme. Lacroix*, white; *Peter the Great*, yellow; and *Excellence*, deep crimson. An extra prize was taken by Mr. Stevens, St. John's Nursery, Putney, whose chief sorts were *Ceres* and *Mrs. Charles Carey*.

The best collection of twenty-four cut blooms was shown by Mr. Walters, Sunnyside, Burton-on-Trent. His best blooms were of the following: *Ceres*, *Meg Merrilies*, *Baronne de Prailly*, *Boule d'Or*, *Duchess of Albany*, *Marguerite Marrouch*, chestnut; *Fabias de Maderanaz*, *Sunflower*, large yellow *Anemone*; and *Mons. Freeman*, rose-pink.

Mr. Stevens, of Putney, was second, his best blooms being of *White Ceres*, *Mrs. C. Carey*; and Mr. Hamlin was third with a stand of *Princess Teck*, fairly good blooms.

The best dozen blooms were from Mr. Stevens, Putney, who had a really good stand containing the following sorts in fine condition: *Ceres*, *Mrs. Carey*, *Duchess of Albany*, and *Jupiter*. Mr. Walker, of Staines, was second, his blooms of *Princess of Teck* being the best; and Mr. Seale, of Crediton, was third. The best twenty-four *Japanese* blooms were from Mr. Stevens also, and again he had *Ceres* and *Mrs. Carey*, very fine, two sorts he seems to grow rapidly. The best twelve *Japanese* blooms were from Lord Brooke's gardener, Easton Lodge, Dunmow. He had good blooms of *Sceptre Toulousaine*, *The Daimio*, *Boule d'Or*, *Thunberg*, *Belle*

Paule, *Fanny Boucharlat*, *Comtesse de Beauregard*. Mr. Stevens' second best dozen blooms were again of *Ceres* and *Mrs. Carey*; and Mr. Walker's third dozen contained *Fabias de Maderanaz*, *Boule d'Or*, and *Jupiter*. Mr. Owen showed the best six blooms, which were of *Ceres*, *Golden Gem*, *Le Spectre Toulousain*, *Baronne de Prailly*, *Mons. Ivon*, and *Mons. Freeman*. *Boule d'Or*, *Belle Paule*, *Comtesse de Beauregard*, *Fanny Boucharlat* were the best in the second half a dozen.

Mrs. Norman Davis, a new yellow reflexed, was shown by Mr. E. Mizen, Mitcham, who had a stand of four dozen fine blooms. It is evidently a first-rate late sort, and Mr. Mizen, being a market grower, no doubt sees its value for his work. Mr. Waller, of Norwich, sent a golden yellow sport from *Ethel*, which appears to be identical with the new *Mrs. Jones*. A new sort, showed by Messrs. Carter, High Holborn, was highly commended by the committee. Its flowers are bright yellow, and may come larger another season. The two best new sorts shown were *Mrs. Jones* and *Golden Gem*, referred to elsewhere.

First-class certificates were awarded to the variety *Golden Gem*, the same as that shown and certificated the day previous at South Kensington, and also shown by Mr. Owen, who won a certificate likewise for his *Princess Blanche*, a large-flowered, reflexed *Japanese* with pure white flowers. A dwarf plant was shown carrying three fine blooms, and this represented the natural growth of the variety, it is said; if so, it will be valuable.

CHINESE PRIMULAS were as great a feature in the show as the *Chrysanthemums*, and as there was a class set apart for them, some first-rate specimens were shown in competition. No finer lot of plants could be seen than the collection to which the first prize was awarded. This was shown by Mr. Braid, of Winchmore Hill. He had some good sorts, too; one of which, named *Braid's Seedling*, was of exceptional merit. It has brilliant carmine flowers, with a central zone of an intensely deep crimson. It is one of the finest sorts we have seen. The second collection, from Mr. Holmes, Upper Tulse Hill, was not inferior in point of quality. Messrs. Carter, of High Holborn, who make a specialty of *Primulas*, had a large and varied collection of sorts, which they have wisely named according to their colours, and hence may be termed the *Holborn* race. Thus there are the *Holborn Carmine*, *Vermilion*, *Salmon*, *Blush Carmine*, *White*, *Rose*, *Mauve*, and *Gold Leaf*, the latter with with pale gold foliage. It is an excellent series, and was shown admirably. Besides the *Primulas*, there were miscellaneous groups of plants. Mr. Wright, of Lee, took a special prize for a large mixed group, in which forced bulbs were a feature. An excellent group was also shown by the secretary, Mr. Holmes, of Framp-ton Park Nursery, Hackney, but lacked the variety which Mr. Braid had in his group. Messrs. Sutton, of Reading, showed the large collection of *Primulas* they had at South Kensington on Tuesday, and were awarded another silver medal here. *Primulas* were shown very finely, too, by Messrs. Cannell, of Swanley, who possess one of the finest collections of single sorts in the trade. There were many kinds shown, the following being those we thought the best: *Delicata Improved* (pink), *Swanley Purple*, crimson; *The Queen* (white, very large), *White Perfection*, *Swanley Purple*, *Emperor*, and *Swanley Giant*.

First-class certificates were on this occasion awarded to Messrs. Sutton, Reading, for eight of their *Primulas*. Six of these were the same as those certificated on Tuesday by the Royal Horticultural Society, the two additional sorts being the *Single Blue Fern-leaved*, which has flowers of rather a richer tint than the plain-leaved *Blue* and *Double Carmine*, which is as pretty as the *Double Red*, but not so effective in point of colour. Messrs. Cannell were awarded a certificate for their lovely new sort *White Perfection*, which we imagined is matchless as a white both in habit, flower, and purity.

Names of plants.—*F. H. L. (Gynanthus)*.—1, *Cyrtanthium falcatum*; 2, *Pteris cretica*; 3, *Phymatodes pustulata*; 4, *Eranthis umbellifera*; 5, *Hibiscus Cooperi*.—*S. (Gynanthus)*.—1, *Pinus excelsa*; 2, *Pinus rigida*; 3, *Pinus Strobus*; 4, *Pinus excelsa* var.; 5, *Pinus pithusa*; 6, *Bupleurum fruticosum*; 7, *Illicium Alaternis*, var. with narrow leaves; 8, *Myoporum laetum*; 9, *Siphia nana*; not determinable in this state.—*G. Harris*.—*Crotalaria Cunninghamii*.

WOODS & FORESTS.

THE "ART" OF THINNING FOREST TREES.

I did not know thinning had been reduced to an "art," as "J. B. W.'s" remarks last week would seem to imply. It might be called a practice, which each forester carried out according to his own notions, and very often with no clear notion on the subject at all, but that is all. If I was to advise owners of forests, I would say to them, Whatever you do, do not let your woodman do any thinning on the so-called scientific principles of the past, because it may cause thousands of pounds of loss to the estate. "J. B. W.," I presume, has a hankering after the "art" on the old lines, but recent discussion on the subject has apparently made him cautious. He does not believe in Nature's thinning, and yet he gives an example of Nature's way of working that speaks more for that system than all his other statements do for artificial thinning. He writes:—

For example, in thinning a natural plantation of Scotch Fir some years ago, I found a patch of trees in one portion of the plantation about 30 feet high, and growing at a distance of some 10 inches or 12 inches apart. These trees were straight and free from branches, with the exception of small bushy tufts at their summits. Now, had these trees been thinned in early life, there can be no doubt that they would have attained the size of useful timber; whereas by leaving them to Nature they were only fit for paling rails or other similar purposes. These trees, being all about one size, grew up like a crop of Corn or Wheat, but had they been of different sizes the results would have been widely different, as the larger trees would then have killed their weaker neighbours, which is Nature's system of thinning under ordinary circumstances. This may be taken as a fair illustration of the difference between natural forests and such as have been planted.

I have now and then given you examples of Nature's plan and its advantages, but this example, although unconsciously given by "J. B. W." to point a moral in the other direction, is one of the best I have yet come across. Just consider its purport. At the quantity given to the space, a plantation of Firs would produce between 40,000 and 50,000 trees—30 feet high, as regular as "a crop of Corn or Wheat," straight and free from branches—to the acre. Think of it! And "J. B. W." declares he has seen such an example. Be it remembered that, by the old planting and thinning method, half as many hundreds are not grown to the acre by the time the trees are 30 feet high, and then they are pruned afterwards! And these crowded trees were fit for paling rails—a very fair size for the age under any circumstances, because the Scotch Fir is never fit for much else under the most favourable conditions at a height of 30 feet. I presume "J. B. W.'s" "patch" was not old, or he would have "found" it sooner "in one of his plantations." I like to dissect this statement of "J. B. W.'s," because it affords an excellent lesson, although it hardly appears to be read by the author of it. The fair and indisputable presumption is, that if a Fir plantation will rush up to a height of 30 feet, 10 inches asunder, as straight and even as a crop of Wheat, what possible reason can be advanced for thinning young plantations of the same kind planted from 3 feet to 4 feet asunder at the outset, let alone pruning what is left? There is, no doubt, a healthy ratio between the distance asunder and the height attained if we could find it, but apparently there is no need for thinning under ordinary circumstances. This is the conclusion enforced by "J. B. W.'s" example taken on its own merits, but his example is ill-chosen for all that. We do not want a plantation of young rails with presumptions as to what might have happened had they been treated differently, but we want examples of mature timber crops grown on Nature's plan, and these "J. B. W." could have found had it suited his purpose, and had he chosen such examples he would not have been under the necessity of guessing at "might-have-beens." Both in the Highlands of Scotland and elsewhere in these islands, and in vast tracts all over both the temperate and cold regions the natural forests exist, and wherever found the timber is tall, straight, sound, and produced in far greater abundance on the ground than in our artificial plantations, and

also in less time, and the timber beats hollow any thing the British forester can produce by his artificial thinnings and prunings. That is the broad fact, and it is borne out on every wharf and in every timber yard in the kingdom. I am not opposed to thinning when it consists of removing weedy specimens that can be turned to better account at the time, but I am impressed with the wisdom of doing as little in that way as possible.

In conclusion, I would just point out that "J. B. W.'s" acre of poles 30 feet high, and from 10 inches to 12 inches apart, and all so straight and regular, would here fetch nearly £400 at 2d. apiece, equivalent to a rental of £16 an acre, supposing the poles took twenty-five years to grow. This is a result that probably neither "J. B. W." nor anyone else ever attained or approached by the most elaborate culture, and can never hope to attain, and yet it is the example he has chosen—let us hope without reflection—to show how Nature mismanages our plantations. I do not myself claim anything like such results from leaving our woods to Dame Nature, but if there be any truth at all in "J. B. W.'s" figures they show results that are highly encouraging even after being heavily discounted.

YORKSHIREMAN.

SLIDE-RULE TIMBER MEASURING.

I OBSERVE what "Young Forester" says about my answer to a previous query of his regarding the method of calculating the true cubical contents of a tree from the dimensions taken in the usual way. "Young Forester" must be very young indeed if he failed to perceive from my article on timber measuring that I did not suggest any alteration from the customary style in which timber measuring has so long and so generally been conducted, but merely mentioned a method of determining the true cubical contents by slide-rule computation as a speedy way of satisfying curiosity, not as a necessity in timber-buying or selling. There are many questions of extent and quantity that may be asked of the forester or estate manager that are only resolvable by an intricate manipulation of figures, occupying time, and not always resulting in absolute accuracy. Many questions of this kind may be rapidly and correctly solved by the aid of the common slide-rule, which should be a constant pocket companion. A few examples may demonstrate its usefulness, and incite to a further study of its capabilities and general utility. To compute the area of a piece of land, when the dimensions are taken in chains. Set the length in chains on B to 10 on A, then opposite the breadth in chains on A; find the contents in acres, and decimals on B.

Example: What is the area of a piece of land 7½ chains long and 6 chains broad?

A	6 chains	10
B	4.5 acres	7.5 chains

A piece of land is 650 links long and 308 links broad. What is its area?

A	308 links	10	1700 links
B	2 acres	6.50	11 acres

Or a piece of land 17 chains long by 6½ chains wide, would give—by the same setting—11 acres and a small decimal, which practice alone would enable the operator to value approximately.

Should the dimensions be taken in yards, set the length in yards on B to 484 on A, and opposite the breadth in yards on A find the contents in acres and decimals on B. One piece of land is 30 yards long by 20 yards wide, another is 161½ yards by 30 yards, another 323 yards by 30 yards. The areas of these three separate pieces are ascertained from the slide-rule by one setting, as under:—

A	20 yards	484	161.4 yards	323 yards
B	1.21 acre	30 yards	1 acre	2 acres

The figures upon the slide B opposite any width in yards on A up to 161.4 yards would give decimal parts of an acre. And opposite any other figures on A between 161.4 and 323 would give

1 acre and decimal parts of an acre on slide B, with the first setting of 30 yards wide. But if we call the 30 yards 300 yards, and the 20 200 yards, then the reading opposite 2 on A would be 12.4 acres on B, and so on.

To find the quantity of land occupied by fences, roads, or rivers running through an estate or parish. Set 4 on B to 11 on A, and opposite yards wide on A; find area in acres in each mile of length.

Example: A road is 4 yards wide, another is 5½ yards wide, and a river is 20 yards wide. What are the respective areas of each in one mile of their lengths?

A	4 yards	5½ yards	11	20 yards
B	1.46 acres nearly	2 acres	4	7.28 acres nearly

Or, should the dimensions be taken or stated in chains, set 8 on B to 10 on A; then opposite the widths in chains on A; find areas in acres on B per mile in length.

A	2 chains	2.50 chains	4.50 chains	5 chains	10
B	16 acres	20 acres	36 acres	49 acres	8

The diameter of a circle being given, to find the side of a square of equal area. Set 44 on B to 39 on A, then opposite diameter on B; find side of equal square on A.

A	39	find side of = square
B	44	above diameter

The circumference of a circle being given, to find the side of equal square. Set 39 on B to 11 on A, then opposite circumference on B; find side of equal square on A.

A	11	find side of = square
B	39	above circumference

Example: Above 20 on B, find	5.65 on A.
" 30 "	8.47 "
" 60 "	16.94 "

The solution.

The diameter of a circle being given, to find the side of an inscribing square. Set 75 on B to 53 on A, then opposite diameter on B, find side of inscribing square on A.

A	53	find side of inscribing square
B	75	above diameter

The circumference of a circle being given, to find the diameter, and *vice versa*. Set 7 on B to 22 on A, then opposite circumference on A; find diameter on B, and *vice versa*.

A	22	circumference
B	7	diameter

To find the area of a circle in acres. Place 10 on C opposite 11.28 on D, then opposite diameter in chains on D, find area in acres on C, and *vice versa*. Or, place 1 on C, opposite 78.5 on D, then opposite diameter in yards on D; find area in acres on C, and *vice versa*.

To convert imperial acres into Scotch or Irish measures.

For Scotch. Set 5 on B to 3.98 on A, then opposite imperial acres, and decimals on B, find Scotch acres on A, and *vice versa*.

A	3.98	Scotch acres
B	5	imperial acres

Example: In 28 acres, and 70 acres, imperial, how many Scotch acres?

A	3.98	22.2	75.5	Scotch
B	5 gauge points	28	70	imperial

For Irish. Set 13 on B to 8 on A, then opposite imperial acres on B, find Irish acres on A.

Example: In 18, 23, and 60 acres imperial, how many Irish acres?

A	8	11.11	16.2	37	Irish
B	13 gauge points	18	23	60	imperial

Examples might be multiplied *ad infinitum*, but the foregoing may be sufficient to stimulate young foresters and others to study slide-rule calculations, and make further discoveries of its many uses. A. P.

Allowances for bark.—"W. B. H." in his recent article seems to have been in ignorance respecting allowances being made in measuring timber for bark. I should imagine that he never went far from

home, as in every county where I go to measure timber it is a usual occurrence. Never did I come across a man yet so unreasonable as not to allow for bark. It is an absurdity for any forester to object to such, because I believe it a difficult matter indeed in these times for a forester to find a merchant who is foolish enough to buy timber without allowance being made for bark in measuring. Another thing is we never take quarters in girthing; we always allow the odd inches in cubing up the timber. This is not a custom of to-day, but one which has existed between forester and merchant for upwards of 100 years in this part.—YOUNG FORESTER.

The Corsican Pine for timber.—Though a good deal has been written already with regard to the Corsican Pine as a timber tree, I think too much cannot be said in favour of it. I strongly recommend its being extensively planted in woods and plantations with a view to profit, for unquestionably it is one of the most valuable of all Coniferae, and succeeds well where many others would fail. Near the seacoast, for instance, it grows with a vigour equalled by few, but in such situations there should be plenty of other things planted with it to assist in breaking the force of the winds, and, when thinning is done, it should be gradual, as those left get out about through sudden exposure, and sometimes completely uprooted. It seems a pity that so much ground should be occupied about the country by the growth of so many trees that are quite worthless for their timber, and more particularly so, as we are dependent, in a great measure, for all we use on the supplies we get from abroad, but, somehow or other, Spruce appears to have been the favourite with our foresters, but why this should be so I am at a loss to conceive, as it has no special merit beyond its symmetrical shape in an ornamental point of view, and in other respects it is almost worthless, except for fuel.—D.

Disadvantages of mixed planting.—My opinion is contrary to the prevailing fashion on this subject, for we are constantly told that there are certain kinds of trees, such as the Larch, Spruce, and Scotch Pine, which are good nurse plants, and are accordingly recommended to be mingled with the hard-wood and intended to be grown as a protection to it. They are good nurse plants, it is said, because they grow fast. Now this is a very excellent property in any kind of tree, and if with this property they unite strength and durability, which the trees mentioned do to a very considerable extent, then these of all others are those which a view to profit would recommend us to grow. That, however, is not the mode generally adopted, and the Larch, the Spruce, and the Scotch Fir are cut down to make way for the more tender and less profitable growth of a hard-wood plantation. We do not here advocate the growth of these trees to the exclusion of the Oak, the Beech, and other hard-wood trees; all that we here mean is that it is unprofitable to attempt the growth of hard-wood in situations where these nurse trees are required, and it is highly so to use these nurse plants in situations where the hard-woods flourish without them.—M.

Italian Poplar wood.—The Black Italian Poplar for timber purposes is the most valuable; and it is one of the best trees we have for planting on strong, wet, clay soils, on which it thrives well, provided there is no stagnant water. It grows to a great height, and generally leans a good deal to the leeward, especially when much exposed. Owing to its growing so much quicker than any of our other forest trees, it is not suitable for intermixing with them, as it soon overtops them. It should be planted 16 feet apart, and filled up with Birch to 4 feet apart. Its timber is of comparatively little value when it is of small size, but after forty years of age it commands a good price. It is the most suitable for making "breaks" for railway wagons of any of our timber, but for that purpose it must not be less than 14 inches in diameter. In soils unsuited to its growth, such as wet, peaty soils, it is liable to throw out excrescences on the trunk. On good, loamy soil, its quickness of growth is quite astonishing. The White Poplar, or Abele, is the only other species valuable as a timber tree. Unlike the Black Italian, this grows well on damp,

peaty soil, and in such situations it is most valuable to plant; it also grows well on stiff loam. Its habit of growth is not so spiral as the other, but partakes more of the habit of the Oak or Beech, and when grown singly is very ornamental. The timber is most useful when of large size.

ENGLISH FIREWOOD.

PERSONALLY, I would not give a fire of coals for any fire of wood I ever saw, either for warming a room or for cooking, excepting it be in the bakery oven, because it does not make such a satisfactory fire, and to have wood in blocks fit for regular firewood it is almost as dear as coal. These are good reasons, I take it. Still I know wood fires are occasionally preferred by those who can afford mansions, fireplaces in imitation of old-fashioned hearths constructed for the purpose and have forests of their own from which to fetch the wood, and the question of which is the best wood for fuel is an interesting one. Here much of the winter's work for some of the men consists in procuring and splitting firewood, and of the sorts of timber readily available for the purpose, Ash and Birch are preferred to all others, and these are first sawn into lengths about 10 inches long and then split into halves and quarters according to the size of the trunk. The Oak has been condemned as inferior to either, owing to its crackling and sparking, otherwise it gives out a good heat. Probably the best and quietest burners are the Yew and the Holly, whether in the fagot or timber state. There are no better materials for lighting a fire in the woods than the dead branches of either of these. If the twigs are dry they will ignite from a match without any other assistance and burn readily, and the larger pieces burn and glow with an intensity possessed by few other woods. The Scotch Fir burns well, I am told, in the highlands owing to the spirit it contains, and a portion of the root is sometimes lit and carried as a torch at night. So far as I have seen, all woods burn readily when dry, and in this state there is little or no appreciable difference between young and old wood. I imagine "J. C. C.'s" statement on this head to be imaginary. Much depends on the elements of the wood's composition. If these are of an inflammable nature, the wood will burn fast and *vice versa*, but whether these abound most in the old and comparatively inert heart wood or in the young wood is an open question. Still density has a good deal to do with it no doubt. The different qualities of wood as fuel have been ascertained and published, but when or where I cannot at present recollect. I think it has been found that, as a rule, the heaviest timber burns longest. The two bodies on which heat from combustion depends are carbon and hydrogen, and the amount of heat produced by each is different, but much depends on the fire. These are matters, however, which perhaps do not affect the question of the best kind of wood for a grato fire. A wood that burnt brightly, but quietly and at the same time lasted well, would probably answer best, and these, as we have before stated, we find to be Ash, Birch, Holly, and Yew. Y.

The Weymouth Pine (p. 39).—The merits of this as a timber tree are scarcely recognised sufficiently, and I was glad to see some words in its favour. It may not grow, as was remarked, so large as the Douglas, but a tree that will girth an even 6 feet for a distance of 20 feet, as some which I have just measured, is of a very good size for most purposes for which it is likely to be required. They will not grow in too dry a position, but it should be remembered that the greater the amount of moisture which they have at the roots, the less good will be the quality of the timber; hence, though they may be planted in swampy ground, such good results in the workshop are not to be expected. Another point to be noticed with regard to planting is that the closer they are put in together, or are allowed to be drawn up by other trees, the more free will they be from knots.

This, it may be said, is what was to be expected, but it is more noticeable in the Weymouth than many other trees, and one may see specimens with the branches up one side no stouter than a Cedar pencil, and dead stumps sticking out on the other side as thick as a man's wrist. It should be remembered that the sooner the tree, when cut down, is sawn up into planks and put in the dry the better, for if allowed to lie on the ground the ends or any part exposed to the damp are apt to get discoloured and turn blue; whereas when kept under cover the board will work up as bright and nice as possible any time afterwards. For cupboards, shelves, &c., it is most useful, and also for panels in doors on account of the width it may be cut without any fear of curling or winding. Of its appearance as an ornamental tree I need scarcely speak, for the glaucous green heads appearing about among the woods in contrast with the colours of the Scotch, Spruce, &c., is always pleasing. Lastly, it has the recommendation of producing an abundant supply of cones which are usually covered with turpentine, and invaluable for lighting or drawing up sulky fires in a house. I should like to see Pinus Strobus planted more extensively than it is. I am reaping the benefit of the wisdom of one of my ancestors in this respect, and in my gratitude intend to follow the good example set me.—C. R. S. D., *Sussex*.

Weeping trees.—The association of the common Weeping Willow with water leads people to think that it will not succeed elsewhere; but there are few spots, even away from water, in which it will not thrive if the soil be deep. I have seen really grand specimens of it growing on lawns. Scarcely less beautiful is the Weeping Birch; for, although its spray is not so long as that of the Willow, yet, owing to the tree being more lofty, it is nearly equally effective. Not so graceful perhaps as either of these, but a better arbour tree, is the Weeping Ash. Owing to its extremely pendulous habit, it is necessary that it should be worked on very tall stocks, as if height is not secured at first, it cannot be obtained afterwards. The Weeping Ash should be planted in quiet, secluded spots, where, when fully grown, it may form a pleasant retreat during sunny days. It will be found that a tree with a stem considerably bent or inclined at the top will form the most convenient arbour tree, as the position of the stem will then be at one side, instead of in the centre.—A.

Qualities of the Austrian Fir.—Some twenty or thirty years ago it was written of this Fir that "so highly is it esteemed by many, that it is thought it may ultimately supersede the Scotch Fir, but for the higher price of young plants which has hitherto acted in some measure as a check upon its universal diffusion." The tree, it appears, has a greater adaptability for different soils than the Scotch Fir, produces better timber in the south than the latter does, and is a far better tree for shelter. The Austrian Pine is now much commoner and cheaper, and, speaking from experience of it on a large scale with living trees of all ages up to about forty years, I am prepared to say that the Scotch Fir cannot be compared to it in any way under equal conditions in the south. It has been planted on a more extensive scale here during the past twenty-five years than any other Fir save the Larch and Scotch Fir, and, in taking a general survey of these plantations lately, it was plain to the most casual observer that the Austrian had the advantage over the Scotch Fir in all cases, both being planted in equal quantities on the same ground. For shelter purposes the Scotch Fir cannot compare with it, and it is not affected by the white blight as the Scotch Fir is in numerous instances, and to a very serious extent, in the same plantation. I notice also that the Austrian Fir contains an unusual quantity of resin—an important factor in the quality of Pine timber, and one which constitutes the main difference between good and bad examples of the Scotch Fir, the best examples containing most resin, and *vice versa*. I am not the only one who has noted this, for I have either heard or read somewhere that the Austrian Fir produces more resin than any other European tree.

No. 792. SATURDAY, Jan. 22, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

THE ROSE OF SHARON.

OF all Biblical plants, the Rose of Sharon is decidedly the most famous, but, curious to say, this flower of all others is the one we know least about. Some commentators affirm it is the *Polyanthus Narcissus*, some the autumn *Crocus*, some the wild Rose, some even the Daisy. Of these, none seem near the mark; some seem even far and away from any mark. Of course there can be no certainty what the flower was; but it seems a plant could be brought forward coinciding with all the passages in which this mysterious flower is alluded to, and this is more than can be said of any previously suggested. The plant I mean is the *Nelumbium speciosum*.

From a comparison of the texts, this Rose is generally conjoined with the Lily (cf. *Eccles.* xxxix., 13), which, if we admit of the supposition that the Lily was the *Nymphaea Lotus* (cf. Kitto's "Biblical Dictionary," article headed "Shushan"), and the Rose the *Nelumbium*, seems very natural. We may note that Herodotus and other ancient historians connect these two plants also; and by this supposition, "a Lily among thorns" can easily be accounted for, as there are thorns on the *Nelumbium*, "which are so hard," says Theophrastus (iv. 10), "that the crocodiles avoid the plant for that reason." This Rose, we see, was a prolific bloomer—"Blossom as a Rose, it shall blossom abundantly" (*Is.* xxxv., 1). It grew in marshes or pools by rivers—"A Rose growing by the brook of the field" (*Eccles.* xxxix., 13). It was evidently well known and highly esteemed in ancient times—"I was exalted as a Rose plant in Jericho" (*Eccles.* xxiv., 14). Lastly, it was used for making garlands—"Let us crown ourselves with Rosebuds before they be withered" ("Wisdom," ii., 8).

The first and most important question is, did the *Nelumbium* grow in Syria? It most undoubtedly did, for we have the testimony of Theophrastus that it grew there. As to the other points, the *Nelumbium* is an abundant bloomer, and identical in its habit of growing; and it is easily provable that this plant was held in high estimation, even as a sacred flower, by the ancient Jews, else it never would have been used as an ornament for the top or finial of the Jewish high priest's mitre (cf. "Josephus," *aur.* iii., 7, 6). As this Rose was used for making garlands for the head, so also was the *Nelumbium*. Indeed, wreaths made of this flower were very celebrated in ancient times. Plutarch (*Isid.* and *Osir.*, 14 and 28) speaks of a sacred *Melilotus* wreath which Athenæus (*Deipn.* iii., 2) tells us was made of the blossoms of *Nelumbium speciosum*, and these wreaths were exported so largely from Naukratis—a town recently discovered on the delta of the Nile—as to be one of the chief exports of that town. Another garland made of the same flower, and called Antinean (*Athen.* *Deipn.*, xv., 6), was, in Egypt, worn as a crown for the head, and in Greece this plant was cultivated, according to Nicander, for its blossoms, which, likewise, were there used for garlands. Another important point in connection with this Rose garland is, that it was generally (cf. context to "Wisdom" ii., 8) used at feasts in the time of Solomon. Now, if the Book of Wisdom be the production of Solomon, it may be presumed to contain allusions to Egyptian customs, as he was

connected by marriage with that country, and what is more common than to see represented on the old bas-reliefs of that ancient nation the Egyptians feasting crowned with the buds and full-blown blossoms of the Sacred Lotus?

Unhappily, from the Hebrew name of this Rose (*Habazeleth*), we cannot obtain any clue, but it must be borne in mind that the Greeks, in translating it, used the word *κρινον*—Lily—the same which Herodotus used for the most noble of all aquatics, the *Nelumbium speciosum*. Of such a kingly flower Solomon might well have said, "I am the Rose of Sharon."

Upper Norwood. PERCY E. NEWBERRY.

GARDEN IN THE HOUSE.

DOUBLE PRIMROSES.

"I HAD a grand display of double Primroses last spring in my window garden, but I am afraid they are not hardy, for I planted them afterwards in the open ground and they all died." Thus writes a grower to whom some were sent for trial. They were found to have no root-hold upon the soil, and they succumbed to the rigours of the winter. The fact is, the plants should have been potted in small pots, in a good soil, pressed firmly about them, and placed in a cold frame. Really, when these plants are bought in October, up to the end of February they should be established in pots. I have bought strong plants, with good roots, in October and November, and potted them; but they have always appeared to make but little use of the roots. There is but little root action until the spring, and when it occurs the feeding roots appear to be put forth from near the lower leaves, and but little use comparatively is made of the old ones. I think the best time to have these Primroses is about the beginning of September, or even earlier; then there is a chance of their doing something before the winter sets in. Some plants came to me last year about the end of August, and, as there were three each of some five or six sorts, I put the three plants of one variety in one pot, round the sides of it, using a compost made up of good yellow loam and leaf mould in equal proportions, with a little sand thrown in. They were fully exposed to all weathers, standing on a cinder border, until about the end of November, when they were placed in a cold frame, and they have done remarkably well. About February they will be potted singly into 4-inch or 5-inch pots to flower, according to the size of their roots, and they will have a compost of loam, leaf-mould, and sand, used pretty moist, and pressed firmly about the roots; they will not have any water for a week at least. I am persuaded that the plants do best when transplanted, if they are put round the sides of pots, as they root better in consequence. The grand old double crimson variety is one of the most difficult to manage; consequently its culture is much restricted. There are many who would be glad to grow it if they could only succeed in doing so. I got a strong plant from Cork some time last year, and potted it; it is doing remarkably well, and growing into a strong plant, and I hope to flower it well in the spring. I think that Mr. Samuel Barlow has hit upon a good plan of growing this charming variety at his place in North Wales; he has planted it on a turf bank facing the north among the Grass, and it is doing as well as can be desired. It is in the company of some choice single and other Primroses, all of which do well on this cool grassy bank. *Crousi fl. pl.* is another pretty variety, but I find it somewhat delicate, and, like the crimson, it wants careful management. *Platypetala* (or *Arthur Dumollin*) is a better grower, and does well in the open ground, in a moist, sandy loam. The double purple is a fine variety also, with large, fully double, crimson-purple flowers; it is a good grower, and one of the best among the double varieties. I am not quite clear what the Scotch Red is; if I get the red double Primrose from some parts of Scotland, I find it is the rose-

coloured variety, with its large double flowers, but they are sparingly produced. It is, however, a very strong grower, yet it is difficult to get anything like a good head of bloom upon it. What I sometimes get as the Scotch Red is like the crimson-purple, which throws up a stem surmounted by a truss of flowers like a *Polyanthus*. But it is very free indeed; I think the freest to bloom of all the double Primroses. But it is possible there is a variety known as the Scotch Red which is quite distinct from the crimson-purple, purple, or the rose. I regret to find that the fine old late or giant yellow (*Cloth of Gold, The Duchess, &c.*) is very scarce this season. It has very large full flowers, and is in all respects a great beauty. Last summer the Hon. and Rev. W. T. Boscawen sent me a double yellow variety, which he informs me is a natural sport found in a hedgerow in Cornwall, and which I hope to flower this season, to see if it differs from the ordinary late yellow. The Scotch have two early-flowering yellow or sulphur-coloured double flowers, but I do not know if they are distinct. The early double sulphur, or Harbinger, as it is sometimes called, is pretty plentiful in places; it is both very early and very free. Everyone knows the double lilac, the commonest, perhaps, of all the double forms, but by no means the least attractive. It is a charming subject in the border in spring, and it and the common white—quite a gem also—will do well in the open air where the others will die. But they want suitable soil—a deep, moist loam—and they do best in the shade. I once saw a large patch of the double white growing in a market garden near London, planted out in the moist soil under some tall fruit trees; but it was found necessary to mulch and water the plants during the summer. There yet remains the blush, which is no doubt a sport from the double white; and, like many other sports, apt to revert to its original form. If I would have it true, I find it necessary to go to the north of Ireland.

Will not some of the readers of THE GARDEN give their experience of these pretty Primroses, and let us describe as many varieties as it is possible to do, so that as complete a list as possibly may be compiled? I have heard it stated that there are as many as sixteen distinct varieties. Who will help to trace them out? R. D.

PLANTS FOR CORRIDORS.

THOSE who have corridors, entrance-halls, and similar places to decorate during winter should bear in mind the merits of the *Laurustinus* for that purpose. Were this fine-flowering shrub not so hardy as it is, we should certainly use it more freely than we do for indoor decoration. But, although it is hardy and flowers well in the southern counties at least, it often does not come well into bloom before spring. Given the protection of a cool or cold house and the blossoms will expand during the winter months, coming just when flowers are scarce. They come, too, much purer in colour than in the open air. The best way to grow the *Laurustinus* for this purpose is in tubs, and if the plants are pinched in a little when young they will form very ornamental, shapely bushes when they reach a large size. *Chamaerops excelsa* is also excellent for such a purpose, as it only needs a little protection from cold, wintry winds and extremes of cold. Bamboos, too, are ornamental and distinct, the variegated kinds giving variety of colour. For this purpose the golden variegated *Eucynmuses* are also valuable. There are two kinds having yellow variegation, and when grown into good-sized bushes they produce an excellent effect. Even in the south of England these variegated kinds are apt to suffer; if they do not get killed outright, they become in hard winters so crippled as to lose much of their distinctive beauty. There are few more ornamental shrubs than the golden variegated *Eucynmuses*, and they are certainly worthy of more care than they usually get. In the summer they should be placed in positions freely exposed to the sun, as a certain amount of solar warmth is necessary to bring out

the golden tints. When they get the conditions they like, not only the foliage, but the stems become finely coloured. The finest plant of golden *Euonymus* I ever saw was on the front wall of a cottage, which it covered. The position seemed to suit it well, and all through the winter it had a most cheerful appearance. Just as it came, however, to its fullest development, an exceptionally severe winter destroyed the greater portion of it. The variegated New Zealand Flax is likewise very ornamental when placed in corridors; it only requires a little shelter to ensure its safety; the golden variegated *Periwinkle*, too, is very ornamental when protected against severe weather.

J. C. B.

SWEET-SCENTED FLOWERS.

THESE are not only highly prized indoors, but in the open garden they are equally appreciated. Some say the best time to enjoy the scent of flowers is in the early morning. Without denying this, it is exceedingly pleasant to walk round one's garden in the gloaming, when colour does not attract so much attention as in bright light. Everything looks different after the daylight has departed, and though the fragrance of the evening may be less charming than that of the early morning, yet the former, as I have said, is very pleasant. The one speaks of peace and rest, the other foretells activity. After nightfall it is easy to tell in summer or autumn when we are approaching a group of Roses, by the perfumed atmosphere which surrounds them. The beds of Pinks, the borders of Thyme, the Marvel of Peru, the common Musk, the *Syringas*, *Mignonette*, the Sweet Brier, the Portugal Laurel, and hundreds of other flowers indicate their presence, even though one cannot see them; each has a perfume peculiar to itself, and each stands as it were in a lake of its own incense. When the Hawthorn season comes round, when the country in the evening is lit up with white blossoms, what a glorious, not-to-be-forgotten time it is! But there is no season of the year when the garden is altogether scentless. I am thinking now only of the early open-air garden; of course, in the conservatory there are always sweet scents abounding, both of leaf and blossom, and the perfume of foliage, being different in degree and character, gives a piquancy to the heavier, denser perfumes of the flowers. At this season the perfume of the Myrtle and *Diosma*, for instance, is exceedingly refreshing and pleasant, and in the open air we have their counterparts in the Lavender, the Bay, the Rosemary, and Sweet Verbena. The latter is growing in a sheltered situation against a warm wall, and though its leaves are withered and falling from the effect of the late frosts, yet when touched they emit an agreeable fragrance. Then, besides the sweetness of flowers and foliage, there is, in the season, the perfume of agreeable fruits. In summer the aroma of the Strawberry floats on the atmosphere, and the Melon and Pine, each in its season, have a fragrance of their own. Trees and shrubs with scented blossoms or foliage are numerous. They include the Limes, Tulip Tree, Horse Chestnut, Thorns, Laburnums, flowering Almonds, Magnolias, double Cherries, Barberries, the Apple, Mock Orange, Lilacs, *Laurustinus*, Spiræas, Elder, Honeysuckle, Jasmine, Portugal Laurel, flowering Currants, Rhododendrons, Azaleas, Gorse, Broom, Kalmias, Sweet Briers, Bays, Daphnes, *Cistuses*, *Wistaria*, *Chimonanthus*, Willows, and last, but not least, the Scotch Fir. Who that has in spring or early summer inhaled the breath, if I may so term it, of a plantation of Scotch Fir, can forget its inspiring influence? Among sweet scented plants of a lowlier character may be named Lavender, and, to be effective, this should be planted in masses. Its appearance in winter as a group on the lawn is quite as effective as most of the plants employed in such positions. Rosemary, Hyssop, Southernwood, all possess a value for increasing the ozone of a garden; also Carnations, Pinks, Sweet Scabious, *Mignonette*, and Stocks. The night-scented Stock is one of the most delightful things imaginable to be sown under the windows. Sweet Peas should be planted in succession, Sweet Alyssum, Lily of the Valley, *Liliums* of many kinds, many kinds of *Hya-cinthus* (including the Musk Hyacinth), *Daffodils* of

many varieties, Water Lilies, *Dictamnus Fraxinella*, Winter Heliotrope, Snowdrops, Violets, Primroses, Mints, Thymes, *Aponogeton distachyon*, Water Flag, Alyssum, *Allium fragrans*, Clematis *Flammula*, Cyclamens, *Funkia grandiflora*, *Galium verum*, *Gypsophila viscosa*, *Hedysarum coronarium*, Candytufts, Irises many varieties, Phloxes, *Collinsia verna*, Lupines, *Malva moschata*, the red Monarda, Woodruff, Myrica Gale, *Pæonies* various, *Panacratium illyricum*, &c. In the grouping of these scented trees and flowers in order to make the garden as pleasant as possible, there is much scope for cultured thought and taste. The trees and shrubs should form picturesque groups. Roses, in all their variations, will be present, and such things as Clove Carnations, Pinks, Musk, Wallflowers, Lavender, Sweet Borage, Lily of the Valley, Violets, Primroses, may be planted in appropriate situations as special features. Climbing plants—Honeysuckles, Clematises, Jasmynes, and Roses—will be allowed free scope for development in the conservatory. All the sweetness culled from numerous exotics will mingle together; but I question if the temperate or tropical regions of the earth can send us anything sweeter or more lovely than the products of the open air gardens can furnish where well planted and cared for.

E. HOBDAY.

NOTES OF THE WEEK.

Euphorbia jacquiniæflora.—This is now in great beauty in Mr. Williams' nursery, at Upper Holloway; although a very old plant, it is still one of the best and most striking for winter-flowering; and, if care is exercised in its treatment, a second crop of flowers is produced from the growth which is made after the first cutting. It is by no means a strong-rooting plant, and, therefore, requires good drainage and care in watering; this refers to both plants in pots and those in borders in stoves.

Strawberry Blite.—This is the English name of *Blitum virgatum*, a name given it because of its resemblance to that fruit. It is a hardy annual, found abundantly in waste places in Southern Europe, and even said to occur in our own country as an escape from gardens. It flowers early in summer, and the calyx increases in size with wonderful rapidity. It becomes fleshy and pulpy, and in the form of a cluster may be found in the axils of all the upper leaves; when ripening it becomes bright red and very attractive. In a cut state it lasts for three or four weeks, and is quite unique in appearance. It does best in a dry, stony soil and in fully exposed places. It was, we believe, first cultivated by Miller in 1759.

The North American Cranberry (*Vaccinium macrocarpum*) is another plant of which too much cannot be said in its favour for winter decoration. In favourable situations, which we find to be peaty soil in full sunshine, and where it can get well drenched during summer, it flowers and fruits freely; the fruits are large, bright red, and very effective all through the winter months. It has a straggling, trailing habit of growth, and is an excellent plant for hiding unsightly banks, old sunk walls, &c. When hanging loosely over ledges or boulders in the rockery it has a handsome appearance. Its fruit is largely used in preserves, and when cooked is said to be very palatable.

Daffodil Ard-Righ.—After the close of the Chrysanthemum season there is generally a scarcity of flowers, and this Daffodil comes in about Christmas to assist to fill the gap. Having a great demand for flowers about that time, I was recommended to try bulbs of this Daffodil, and I am pleased to say that they have greatly exceeded my expectation, for we had them in flower at Christmas and since, and mixed with other forced flowers they cannot be too highly prized, for they keep in good condition for a long time. The secret in forcing these bulbs is, first, to see that you get them well ripened; put three or four bulbs in a 5-inch pot, using any fresh moderately rich soil, and pot firmly. After they are potted, plunge the pots in coal ashes in the open air; when the pots are partly full of roots they should be placed in a temperature of about 55° and in a rather dark

place; gradually inure them to the light and bring them near the glass. Before the flowers open remove them to a cooler house, as they dislike a high temperature, and in a few days a good supply of beautiful yellow flowers will be the result.—W. OSBORNE, *Fota*.

Costus igneus.—The several species of *Costus* in cultivation are not remarkable for fine flowers, though some of them have very handsome foliage, but this one is really a showy, flowering plant. It has blooms some 2 inches across, roundish, and of a brilliant orange colour, which, in combination with the bright green of the broad foliage, makes a particularly fine plant. In the Water Lily house at Kew it has been flowering throughout the winter at intervals, for its flowers, being produced from the tips of the shoots in dense clusters, open in succession. Some days several blooms are expanded; at other times there are none. It is a stove plant, requiring no special culture. Were it a new introduction distributed from a nursery, there would be a stir made about it.

Zechmea Weilbachi.—This is one of the showiest of the many Bromeliads that flower in the depth of winter. It now enlivens one of the stoves at Kew, where it has been in bloom for the past month. The flower-spike combines a great variety of colours, and these are contrasted in an unusual way. The flower-stem itself is a bright scarlet, and so are the long, showy bracts. The flowers are almost globular, and about the size of Peas, and represent almost every colour of a rainbow. The red runs into violet, then that into blue, with subtle gradations, and finally the blossoms die away to a very dark bronzy green. The spike is erect, overtopping the foliage, which is of the usual vasiform character. If anyone wishes to grow a few select Bromeliads, this should be one of them. Another handsome species is in bloom at Kew; it is *Billbergia pyramidalis*, but though bright in colour and quite as showy as *Z. Weilbachi*, it does not possess such interest.

Impatiens Hawkeri.—This new South Sea Island Balsam, which is in the way of *I. Sultani*, but a great improvement upon it in size, substance and colour, is recommended by its distributor for its decorative qualities from the month of March until October, when its large, flat, expanded flowers, which are deep carmine, shaded round a white eye with a lustrous bluish tinge, form a conspicuous attraction in the plant stove. We, however, saw it in the gardens of Canon Bridges, at Beddington, in great beauty at Christmas, and therefore in future it must rank as one of the very best and most showy of winter as well as summer flowering plants. In addition to its free-blooming qualities, too, it is a plant of the easiest culture, and one which all who desire to have bright flowers at this particular season should possess.

Chinese Primulas.—From Messrs. Cannell comes a boxful of *Primula* blooms—all good, both in form, colour, and substance. The dark kinds are very bright and rich and heavily fringed; amongst them, too, is a so-called blue, which we are glad to see is becoming year after year deeper, and doubtless ultimately it will reach the much-coveted shade. The other flowers are all large, measuring from 2 inches to 2½ inches across. *Primula* blooms, remarkable for their beauty, also come from Messrs. Carter, High Holborn. Amongst named kinds the best were Holborn Vermilion, rich deep red; Fern-leaf Pearl, the result of a cross between Holborn White and Holborn Blue; Fern-leaf Red, a soft shade of that colour; others varied from salmon, magenta, crimson, and scarlet to purplish blue. The display made by these *Primulas* at the Forest Hill Nursery of this firm is just now a grand feature.

Gaultheria procumbens.—Looking about for a little bit of something bright after the late snow-storm, we came across a small patch of this charming little Wintergreen or Checkerberry that had been sheltered by a large Pine branch. It was laden with berries of the brightest red, peeping out from amongst its pretty bronzed leaves, and more striking than ever I remembered to have seen it before. For the last month it has been conspicuous, and, with the exception of a few Christmas Roses, it is the only interesting plant which we have just now out of doors. I

should be in every garden, so amenable is it to positions of all kinds. On shady spots on the rockery we have seen it attain a large size, its procumbent branches rooting as they creep along, and forming an evergreen carpet studded with bright coral berries. As an edging, it has a very good effect; it may be easily kept in its place, and it stands any amount of cutting back, which also tends to make what is left thicker and more compact. Boxberry is a local American name for it.

Papaver Hookeri, so called, has developed into a really wonderful variety of forms since its introduction from gardens in Cashmere a few years ago; there can now be little doubt that it is a cultivated form of our native *P. Rheas*. It assumes the most brilliant as well as the most delicate of colours, and may be found in all stages from a single to a double flower; in the latter form it is not unlike a large Rose or Carollia. The French varieties, which are almost identical with the above, are also worth cultivating, and all mixed and sown together in the open border make a really charming display. They seldom exceed 3 feet or 4 feet in height, and when well thinned out branch freely, making well proportioned specimens. The seeds should be sown in strong, rich compost, in which they grow freely, and there need be no difficulty about seed, which they produce plentifully; when a good strain is obtained, it should be taken care of.

Lychnis chalconica.—Of late years this fine old fashioned plant has given way to the variously coloured Pentstemons, which are now so common and truly handsome. This *Lychnis*, nevertheless, need not be banished from our gardens. It may be used with striking effect on the margins of lakes, where it adds a brightness and robustness foreign to it under border culture. When planted in large clumps close to the water's edge, against a dark background, its large flower heads display themselves with striking effect. It was a great favourite with Parkinson, who calls it a glorious flower, and in a print of himself, prefixed to his "Paradisus Terrestris," he is represented with a double form of it in his hand. It continues to flower all through the summer months, and in shady positions continues till well on in autumn. There is also a pure white variety and a pale pink sort in cultivation, none of which are so effective as the old red.

Epacris at Gunnersbury Park.—These beautiful winter-flowering plants, Australian Heaths, as they are sometimes called, are admirably grown and bloomed here, and, as a matter of course, make a grand display. Amongst them are *alba odorata*, a dwarf-growing kind, producing dense racemes of sweet-scented flowers; *Eclipse*, bright crimson tipped with white; *carminata*, bright red; *Lady Penmore*, pure white suffused with soft rose; *hyacinthiflora*, furnished with long racemes of large pink flowers, and its white counterpart, *hyacinthiflora candidissima*. Others are *Sunset*, red, tipped with rosy pink; *Vesta*, a somewhat close and compact form, with fine white flowers; and *Lady Alice Peel*, with flowers large and salmon-coloured. These, with such kinds as *Her Majesty*, *Kinghorni*, *The Premier*, *sanguinea*, and *Impressa*, which is a late variety, make up a fairly representative collection of these lovely greenhouse plants.

Pæonia Whitleyi.—"D. W." (p. 16) asked a question which I expected would have been answered before this, but as I was once puzzled in the same way, I hope I may be able to help him. *Pæonia Whitleyi* was figured in Andrews' "Repository" (plate 612), where it is stated to have been raised in the nursery of Mr. Whitley, from seed brought from China by Mr. Livingstone in 1808, and was the first double variety of *albiflora* which Andrews had heard of. Edwards (*Bot. Rey.*) gives a plate (No. 630) from a plant in Messrs. Whitley's nursery, and refers to the earlier figure. "D. W.'s" plant is probably *Pæonia albiflora laciniata*, which, for some reason or other, has been going about the country as *Whitleyi*. One would have pardoned, or even encouraged, this mistake if it could have made itself a little more common, for it is most certainly a very

beautiful thing, and very little known. It does not increase very rapidly, but is a free bloomer, and has the commendable feature of opening the two side blooms before the centre ones faded, and the variety of form of the fully-opened blossom, with the buds burst or bursting on each side, is very charming. I am afraid that this is not the only instance of a wrong name for a *Pæonia*, and even that they are getting into a good big mess, *Montan* and herbaceous being called the same, and varieties already known as one thing being rechristened as something else. I hope that the Royal Horticultural Society may be able to have a *Pæonia* conference before long (we could scarcely have a more magnificent flower for the Jubilee Year), and appoint a committee to take the class in hand, as has been done with *Daffodils*, so that, with the help of Mr. Baker's work among this family, we may interest people in getting together rare or unknown species, and also put some check on the indiscriminate naming of seedling forms which is likely to overwhelm us, now that the flower is becoming so popular.—C. R. S. D., *Sussex*.

FLOWERS AND FOLIAGE ON WALLS.

As a fresh, bright-looking wall plant, pleasant to look upon all the year round, Ivy has no equal. It is vigorous in growth, and will thrive on all aspects, even on bleak north or eastern exposures almost as well as when facing the south or west, provided it has good rich ground to grow in. Though Ivy will live on scant fare, such as very few plants can exist at all upon, still, when subjected to semi-starvation, it makes little progress compared with what takes place when its roots have an unrestricted run in good soil. The common Virginian Creeper (*Ampelopsis hederacea*), as a strong, vigorous plant that will cover a large space in little time, is without a rival for elegance of habit, and the beautiful tints of the decaying leaves in autumn are not the least of its desirable properties. This plant will grow and look healthy under the disadvantages of little and indifferent soil, and also where the atmosphere is charged with smoke and dust that would be fatal to most things. Its only drawbacks are that it requires fastening to the wall, and that, being deciduous, it leaves the wall bare and cheerless in winter. *A. Veitchi*, like not a few other good plants, has been slow in making way, but it is now receiving the attention at the hands of those who require wall climbers that it deserves. It is amongst the freest of free growers, covering a large space in little time, and thriving on any aspect. It clings so tenaciously to anything on which the shoots can lay hold—bricks, stone or wood alike—that no attention is required in the way of fastening it. The vivid crimson colour which its leaves put on in autumn is unequalled, and the leaves remain on the plant in their brilliant condition much longer than those of the old Virginian Creeper. On a northern aspect the colour of the leaves is paler than in the south, but they remain longer on the plant when facing northwards than under the sun's direct influence. All through the summer its pale green foliage, covering the wall as evenly as if the leaves had been placed there by hand, has a beautiful appearance, but it is wanting in the elegant drooping character of its shoots which the old kind possesses; as a matter of course, the wall on which it is grown is bare in winter, save for the presence of the long wiry shoots.

There are several kinds of evergreen plants that, although seldom used for the purpose, make good-looking coverings for walls of moderate height, say up to 18 or 20 feet. The different sorts of Japanese *Euonymus*, green and variegated, and *Azara microphylla* look well on walls. The *Azara*, though it has been some time in this country, is yet comparatively little known; the spreading fan form of its branches adapt it for covering walls. Its character of growth is like that of *Cotoneaster microphylla*, but it is a much quicker grower, and will cover a deal larger space. The branches naturally assume such a spreading form, that they require few fastenings to the wall. There are few plants with leaves that possess a more pleasing shade of green than the *Euonymus*, whilst those who like variegated foliage have choice in the

different varieties of the yellow and the white variegated forms; but the green, self-coloured sorts look best. In good soil the plants soon make headway, covering a considerable space in little time. In the use of these and all other plants for clothing a wall, care should be taken at the beginning to train the strongest shoots out horizontally, so as to furnish the bottom space at first; otherwise unsightly bare places will remain for years uncovered. It is particularly necessary to avoid these when plants like these *Euonymuses*, with an erect habit of growth, are used. The small-leaved *E. radicans* variegatus, as it is usually seen in the form of a low-spreading dense little bush, or as an edging, looks an unlikely subject for clothing a wall; but, so used, with a little attention in training the shoots at first, it soon makes a dense covering up to a height of 8 feet or 10 feet. But there is one thing that must not be lost sight of in using the different varieties of *Euonymus*, as well as the *Azara*, that is, they are not sufficiently hardy in all parts of the kingdom to stand exceptionally severe winters, not even when they have the protection of a wall when the aspect is east or north.

So far these remarks have referred to the plants named when used singly, but to have wall climbers in the way that will produce the most elegant effect, several kinds require to be grown together in a manner that will admit of their branches intermingling amongst each other with no more interference than is necessary, to prevent the stronger growers encroaching too much on the weaker ones. Roses, Clematis, *Jasmines*, *Bignonias*, *Honeysuckles*, *Passifloras*, and the like are beautiful when seen singly or with each a space to itself on a wall; in this way they are usually grown, but so managed, they are wanting in the elegant effect produced where they can scramble about loosely with a covering of Ivy behind them. So treated, the flowering plants with the background of dense foliage present an effect such as is not obtainable when they alone are present. This may often be seen where an odd branch of a Rose or a *Honeysuckle* outstretches the space allotted to it, and rambles over something else. But that which thus occurs by accident can be done much more effectually when the necessary consideration is brought to bear on the planting. But in a mixed arrangement of this kind there is a difficulty that makes its appearance in a few years after the planting has been effected. Ivy is a gross-feeding plant, and pushes its hungry roots far and wide in all directions, soon exhasting the soil within its reach to an extent that reduces other plants associated with it to a state of starvation. When planting the first wall that I intended to clothe in this way I had some misgivings that this might occur, but supposed that the difficulty might be got over by subsequent applications of manure when the soil became poor. In this I was mistaken, for the more that was done in this way, the more persistently the roots of the Ivy laid hold of every particle of soil in the border, so that the *Roses*, *Clematis*, and *Honeysuckles* associated with it were not able to hold their own. The best means of avoiding this is to partition off stations for the blooming plants, so as to prevent the roots of the Ivy interfering with them. This is easily done by the use of thin concrete walls when the border is being prepared. This material is much more effectual than slates or stone slabs, between the divisions of which the roots of plants soon find their way. The concrete divisions need not be thicker than about 3 inches, as there is no pressure against them. In this way the flowering plants have the spaces allotted clear to themselves. Whatever plants are associated with Ivy in this manner should have the principal branches secured to the wall, but nothing more. The lateral shoots that spring from these ought to be no further interfered with than in keeping them thinly dispersed, allowing them to come as far away from the surface as they like.

In selecting the kinds of plants for growing in company with Ivy in the way indicated, it is obvious that they should be deciduous and of a somewhat thin, straggling habit. If close growers, unless the knife is freely used they get so dense that they darken and weaken the Ivy so far that it is apt to suffer in hard winters. *Roses*, *Clematis*, *Bignonia adicans*, *Jasminum nudiflorum*, *Glycine sinensis*

Aristolochia Siphocarpoides, *Passiflora carulea*, and its varieties are amongst the best things that can be used, in all cases having their shoots far enough apart on the wall to begin with, and keeping them so afterwards. Not only is an arrangement of this kind infinitely better, so far as regards the appearance of the flowering plants when they are in bloom than when grown by themselves, but there is the advantage of having the wall covered effectually in winter; whereas when it is occupied by deciduous plants alone, when they are leafless it looks anything but inviting.

B.

WET AND DRY BULB THERMOMETER.

The remarks of "Enquirer" (p. 28) open up a wide field, and really mean a more intimate knowledge of the native habitats of our many exotics and the different conditions of temperature under which they flourish, this last being a most important feature, as the announcement, for instance, that a plant came from Peru might mean the foot of the Andes or the table-land of Quito. It has always seemed to me a lamentable fact that this more close knowledge of temperatures, undoubtedly of so much interest to the gardener, is so little dwelt upon in books of travel; true, we often get remarks on the temperature at a certain time, but what we want to know particularly is a comparison of the day and night readings, and also of the relative positions of the wet and dry bulb. In a book published some years ago treating of a voyage up the Niger these facts were gone into very minutely, and I was much struck at the time with the remarkable evenness of temperature chronicled therein; thus, for days and weeks the day and night readings stood between 80° and 85°, and the difference between wet and dry bulb was between 3° and 5°, and under these conditions the voyagers were encountering a dense and luxuriant vegetation. I take it, a fairly equable temperature is most conducive to the well-being of stove plants with us, and, so far as my own experience is concerned, I have found the difference named above about 4° or 5° the proper humid temperature for the same, and also for growing Cucumbers, Melons, &c. A few degrees' difference either way will naturally be no detriment to plant life now and then, but if this becomes a regular thing, and the wet bulb indicates a state of saturation in equality with the dry, or some 9° or 10° difference, the health of the plants will speedily suffer. It is the latter condition out of doors in March that makes it at times an awkward month for forcing, especially if there are not plenty of appliances at hand to generate moisture, and the same remark holds good in the case of all fire-heated structures, the heat given out being so much drier.

It is not, however, necessary to go either to the Niger or inside our stoves to learn a lesson on the value of a true balance between the two bulbs; it can be illustrated after a warm shower in May or in the mild, genial Turnip weather that we sometimes get in the early August evenings, when, to use a common expression, one can almost see things grow. Naturally, the temperature of all structures devoted to flowering plants should be on the dry side, but it is a certain fact that all greenhouse stuff in a growing state is (no less than stove life), in its particular temperature, better where the balance is not more than 6° on the dry bulb side; and if the thermometer is maintained nearly at the figure often quoted in *THE GARDEN*, "Enquirer" will find little difficulty in keeping a genial growing temperature, as a lower reading of the thermometer with no outside wind is naturally conducive to a closer union with the wet bulb. One of the chief points to be taken into consideration in dealing with stove exotic life, requiring, say, a summer minimum of 70° and a winter of 60°, is a moderate heat from plenty of piping as against a strong heat from a limited surface, for under the latter conditions the moisture generated is not steadily maintained; there is at one time the temperature of a tropical forest after a storm and at another that of a sandy desert—a very bad state of things

where good growth and healthy plants are required. I think if "Enquirer" is anxious to study the question of temperature in all its aspects, a walk through any very large London nursery will be the very best thing he can undertake; he will find Orchids, stove plants, Ferns, aquatics and greenhouse plants all as well provided for as it is possible for them to be in this country.

Clarcmont.

E. BURELL.

PROPAGATING.

CALADIUMS.—Owing to the weather which we are now experiencing, propagating operations of most kinds are at a standstill, the principal work in this department being attending to cuttings of various sorts that are still in propagating cases, and keeping them clear of decaying leaves, as during this weather large quantities of delicate cuttings will damp off in a few days if in any way neglected. Where it is desired to increase the stock of Caladiums, the old corms that have been wintered either in sand or in pots must now be taken out, potted in light open compost, and plunged in a gentle bottom heat. After being kept moderately dry throughout the winter they will not require any water for a few days, as the moisture in the soil will at first be sufficient. Thus treated, they will soon commence to grow by pushing up leaves from various parts of the corm if a large one, but should it be small, probably only one crown will start into growth. As soon as the first leaves are fairly developed, the corms must be turned out of their pots and all the soil should be shaken from them, when it will be seen that at the base of each cluster of leaves there is a quantity of new roots. Then, as each shoot takes its start from a small protuberance on the corm, by using a sharp knife all the crowns can be easily removed, with their attendant roots. They must then be potted in small pots, using light sandy soil for the purpose. They will soon become established, and can then be shifted into larger pots as required. If the old corm whence all the young shoots have been removed be again potted and treated as before, another crop of young plants will in time be obtained. By this method large quantities can be propagated from but a few good healthy corms.

LILIES.—As many people pot the different kinds of Lilies just now, a good opportunity is afforded of increasing any that may be required by means of scales. If these are detached from the parent bulb and placed under favourable conditions they quickly form small bulbs, but from the readiness with which most Lilies are imported this operation is seldom resorted to, except in the case of the very floriferous form of *L. longiflorum*, known as *Harrisii*. This Lily has rapidly advanced in popular favour within the last few years, and is now extensively grown. Several of the outside scales can be removed from the bulb without injuring it in any way, and if broken in two they grow just as well. These scales must then be laid thickly, without touching each other, in well drained pans or boxes, filled to within an inch of the top with a compost consisting of loam, peat, and sand in about equal proportions. After this sprinkle over just enough sand to cover them and then about half an inch of soil, when they may be allowed to remain undisturbed till they begin to grow. If placed in a cold frame they will lie for a month or two, but where assisted with a little heat the young plants will soon make their appearance. To obtain the best and quickest results, when the young plants are well above the surface, and have consequently a few good roots, they must be potted off and sheltered by a frame till frosts are over, when, if they are then planted out in a prepared bed, under favourable conditions, a few will bloom the first year. Of course, the number of flowering bulbs will not be great, and each stem will bear but a single blossom; still such a rate of increase is very rapid, and is, as far as I am aware, unapproached by that of any other Lily. In the case of some kinds, notably the

Tiger Lilies, a ready mode of propagating them in quantity is afforded by the small bulbils borne on the stems, which grow wherever they may chance to drop.

SEEDS OF VARIOUS PLANTS may now be sown, including among their number a few subjects that may be required for outdoor decoration during summer, and which are needed to be of a good size by that time. To this class belong *Echeverias*, that is to say, where it is necessary to raise them from seed, as they make but slow progress during their earlier stages, and consequently need a considerable time before they are large enough to be effective. As the seed is very minute it is best sown in shallow pans, well drained, and filled with very sandy soil finely sifted. The seed having been sown on the surface, a very slight sprinkling of sand may be given by way of covering. A good place for the pans then is on a shelf in the stove, where they are free from drip, as an excess of moisture is fatal to the young plants. Such being the case, the soil in the pans must be kept just slightly moist, and when the plants are large enough they can be pricked off. In the case of some very hard seeds, such as those of *Cannas* and similar subjects, various suggestions have been made with the view of hastening germination, one proposal made, and, indeed, it is frequently followed, being to file partly through the hard exterior, in order to liberate the young plant. A better plan, however, than this is to soak the seeds in water for a few hours and then sow them, when they germinate readily enough. One thing to bear in mind in this case is, that as the seeds are so very moist they must not be allowed to get at all dry, otherwise the germ is liable to be injured. Palm seeds should be sown as soon as possible after they are obtained, as some kinds soon lose their vitality, and those that do not, lie in the ground much longer than new seed. Palm seeds of all kinds are fairly well amenable to one course of treatment. Boxes or pans of about 3 inches in depth are suitable for most kinds, and they must be prepared for the reception of the seeds in the following manner: A thin layer of broken crocks should be placed on the bottom; over that let the soil be put and pressed down moderately firm, to about 1 inch below the surface. Then, on this the seeds should be sown, and covered with a depth of soil equal to their respective sizes. A compost well suited for such a purpose consists of about three parts good open loam, to one of sand, the whole being sifted through a sieve with a half-inch mesh. Should the loam be too adhesive, a little decayed leaf-mould or peat may be added. These pans or boxes may then be set on a stage in the stove, or in some similar position (for even greenhouse kinds are benefited by a little additional heat during their earlier stages), till the young plants make their appearance, and are sufficiently advanced to be potted off. The best time for that operation is just as the first leaf that makes its appearance is fully developed, for if delayed later the roots become entangled with each other.

T.

Impatiens Lucie.—This Balsam has no pretensions to rival the now popular *I. Sultani*, or its later relative *I. Hawkeri*, but it is, nevertheless, a very pretty plant, and a most desirable one for winter bloom. It resembles the two mentioned Balsams in habit of growth, and the flowers are larger than those of *I. Sultani*, but as there is more purple in the flowers of *I. Lucie*, they are not at first sight so pleasing. It continues to produce an abundance of bloom throughout the winter without any particular attention. We saw it lately in the St. Albans Orchid Nursery growing like weeds upon one of the rockeries among the Orchids planted out. It was, we believe, distributed from one of the Belgian nurseries, but does not appear to be much known in this country.

At a committee meeting of the National Auricula (southern section), Primula, and Carnation and Picotee Societies, held the other day, the prizes offered by the trustees of the Turner Memorial fund were accepted. The balance in favour of the Auricula Society was stated to be £27 ls. 4d., and that against the Carnation and Picotee Society £6 lbs. 1d.

ORCHIDS.

W. H. GOWER.

SACCOLABIUM BLUMEI MAJUS.

THIS belongs to the so-called East Indian Orchids, a section which includes the genera *Aerides*, *Vanda*, *Saccolabium*, *Renanthera*, *Angraecum* (although this is exclusively African), *Sarcanthus*, and various others, all of which are destitute of pseudo-bulbs, but have erect stems with leaves arranged in a two-ranked (distichous) manner. The meaning, however, usually intended to be conveyed by the term East Indian is, that these plants require a greater amount of atmospheric heat than other Orchids; but numbers from the hills of India thrive admirably in our plant houses, side by side with those from the mountains of the western hemisphere. It is, however, true that the majority of these distichous Orchids do require a good deal of heat, but, nevertheless, not greater than the majority of other stove plants. The mountain regions of South America have during the past few years been diligently searched for orchidaceous plants, and immense quantities of new and beautiful kinds have been sent home from there, and the fact that these mountain plants require but little heat has made them fashionable, to the detriment of the eastern *Saccolabiums*, *Vandas*, &c. Recently, however, some fine new varieties of these plants have reached us, and on that account a reaction has set in in favour of this section, a circumstance not surprising when we take into consideration their extremely ornamental appearance at any season, even when destitute of bloom. *Saccolabiums*, when in flower, are especially elegant, a statement which a glance at the annexed illustration will amply verify. They are, however, somewhat slow-growing plants, and their beauty when not in a flowering state is not so apparent as that of a fine *Aerides* or *Vanda*. The *Saccolabium Blumei majus* here portrayed was grown in the gardens of Mr. C. Mitchell, Jesmond Towers, Newcastle-on-Tyne, and the beautiful raceme and the ramification of its roots conclusively prove how well its requirements have been supplied. This species is a native of Moulmein, Java, Luzon, and other islands of the Philippine group. Its leaves, which are some 12 inches or 18 inches long, are blunt at the ends, as if bitten off, thick and fleshy in texture, and light green in colour. On the underside they have a few parallel dark green stripes, which traverse their entire length. As will be seen, the flowers are in pendulous racemes, long and handsome. In the typical form they seldom exceed a foot, but in the variety *majus*, which is more robust in habit, they are frequently 2 feet in length; the sepals and petals are white, faintly flushed with soft rose and dotted with magenta; the lip is recurved and bright rosy magenta. The variety *Russellianum* is a rather fine, robust-growing form, with massive densely-flowered racemes of richly spotted blooms, fully 2 feet or more in length. All the forms of this *Saccolabium* produce their flowers from about midsummer onwards through the autumn months, and some-

times even into winter. *Saccolabium Blumei* luxuriates in heat, light, and moisture; it therefore thrives best when suspended in either pots or teak-wood baskets. Thus placed, the plant obtains all the light possible, but it should never be forgotten that it is under glass, and not in the open air with the summer breezes blowing upon it, and that too much exposure to the direct rays of the sun will burn the leaves and permanently disfigure them; therefore, air must be freely admitted and a light shade should be used during the hottest and brightest part of the day; the atmosphere, too, should be kept well charged with moisture. In winter *Saccolabiums* require rest, but this should be brought about by lowering the

so that its size does not prohibit it from being grown even in a Wardian case. Its large flowers are produced from the summit of the growth; they are thick and fleshy in substance and rich rose in colour, except the disc, which is yellow. They remain several weeks in beauty if the air is kept dry and they are not sprinkled with water.

DOES ORCHID CULTURE PAY?

YES, it does, must be the reply that "W." (p. 41) will get from many growers if they allow the real state of affairs to be published. I know one private garden in which a collection of Orchids has been worked on a good system for some years, and by judicious management it has returned almost the whole amount expended in its purchase, and there is a fine collection left, which may be said to have cost nothing. This has not been done with a few species or specialities, but has been achieved by growing all sections of Orchids (and hardly excluding some botanical curiosities) from the hottest and dearest to the coolest and cheapest. Now, a word as to "catches" in small Orchid collections that almost pay for the whole collection. *Odontoglossum Pescatorei*, Knox's variety, bought at 2s. 6d., was sold in two years for £165. Surely this has paid my friend Mr. Knox; at least he can say his Orchids do not lose him much money. Look at the scores of plants that are bought at a few shillings, and which sell for as many guineas a year or two afterwards. Go into collectors' houses; see some of their greatest rarities, and they will frequently tell you that "that plant cost me a few shillings." I do not aver that no Orchids are a loss, but I maintain that Orchids bought, grown, and sold judiciously do pay, and handsomely too. I speak from experience, and if "W." cares to come and see my collection, which is close to London, I can show him many a plant bought at a trifle comparatively with its present value.

"W." seems to fall foul of the "out-of-bloom" garb of an Orchid. He surely will allow that a fine *Vanda* tricolor is not an unornamental object in a collection of fine-foliaged plants in any stove house. Again, a houseful of *Cattleyas* and *Laelias*, especially *L. purpurata*, even when out of bloom is handsome if in good condition. "A shelf of mixed Orchids" seems hardly a criterion by which to say they are unornamental. "W." asserts that blooms in an Orchid collection are, as a rule, few and far between, and that the normal condition of the plants is scraggy; but allow me to tell him that in a well-managed collection the houses are hardly ever bloomless. Orchids when grown as a secondary object to other plants are

not always a failure, as many who do so can say if they will; but here I cannot speak, as they are my primary object. "W." also speaks of Orchid culture in private gardens being evidently on the wane. How can this be when every year their culture is being taken up by new votaries to this "increasing mania," as I hear it called sometimes? True, "W." says that the reduced labour entails sacrifices in gardens, but he may rest assured that if one gives Orchids up, there will ere long be another and another to take his place. Compare the number of Orchid fanciers now and ten years ago, and the result will show whether or not Orchid culture is on the wane.—DE B. CRAWSHAY.

temperature and reducing the atmospheric moisture rather than by drying the plants in heat at that season. The temperature during the night may be about 60°, raising it with fire-heat some few degrees during the day. No water should be allowed to remain on the leaves at this season, but the roots should be kept sufficiently moist to prevent the foliage from shrivelling.

Cattleya dolosa.—This elegant dwarf *Cattleya* is now in bloom in various collections round London, and is a welcome addition to the numerous Orchids which help to make plant houses gay at this season. Its pseudo-bulbs seldom exceed 6 inches in length, and the leaves, which are in pairs, are not so long even as the pseudo-bulbs,

Saccolabium Blumei majus Engraved for THE GARDEN from a photograph.

truisms, I must say that its whole tenor is to place the culture of Orchids in an unfavourable light. Orchids have been and are still very popular, and their culture is easy enough to one who knows anything about plants. I believe, in fact, that an amateur practically unacquainted with gardening would be less likely to succeed with the culture of Cape Heath or New Holland plants than with that of Orchids. There is, however, no royal road to success in plant culture, and, therefore, even Orchids cannot be grown without failures and many retracings of steps taken in the wrong direction. The chief difficulty lies in "letting well alone." In the culture of Orchids it is a golden rule when a plant is doing well to let it be undisturbed. One good amateur grower with whom I was acquainted used to state that Cattleyas should be potted only once in seven years. I have seen his Cattleyas, many of the roots of which were interlaced round the pots, and all the young roots which issued from the base of the recently formed bulbs sought nourishment outside the potting soil. I bought some of these Cattleyas about fifteen years ago, and have them now, although I do not grow them on the system just adverted to. One grower, indeed, succeeds in one way, another in another: but this I may affirm, that no one will be entirely successful who does not personally minister to the wants of his plants, or has some one to do this for him. I have often heard with impatience the remark made that some one "has a fine collection of Orchids, and what is most surprising is that they grow without any care or attention being bestowed upon them."

Orchid culture, I feel certain, will pay if the plants are kept in good health; when sold they must also be quite free from all insect pests. Some discretion must also be used in purchasing plants; sometimes grave mistakes are made by injudicious purchases, especially at sales. I attended a sale of Orchids recently, at which very high prices were paid for imported Cattleyas; they looked in perfect condition, but sufficient account was not taken of the probability that the plants, well furnished though they were with fresh green leaves, had been exposed to cold, which had greatly impaired their vitality. After a week of exposure to the genial temperature of an Orchid house many of them were not worth a third of what they cost. In the profit and loss account a depreciation of 75 per cent. is a serious matter; it is a loss, however, that some of the best cultivators had to face after the sale in question. This does not often occur; as a rule, the Orchids sold at auction rooms in London give very satisfactory results, but purchasing plants from equatorial regions at mid-winter in an open sale room is very hazardous. From my own experience, I may say that I have purchased Orchids both at sales and at nurseries, and have in a few years grown the plants into specimens worth ten times the original cost; by this I mean the price that they would realise in a sale room. I have never been in a position to purchase Orchids of any kind at fancy prices, although with good cultivation and care in making purchases, I have no doubt whatever that they would pay even better than such as are more common. I have attended all the principal sales in London during a period of twenty-three years. During that time I have witnessed the dispersion of some celebrated collections, such as that of the late Mr. Sigismund Rucker, the Meadowbank Orchids, and others, and whenever the plants have been in good condition they have realised good prices. In fact, well-grown plants of any kind are always required; whereas inferior material is not wanted at any price.

The decorative value of Orchids is another matter. Everyone must know that there is no comparison between Orchids and Roses during the months of December, January, February, and March. Although good Roses may be obtained in those months, that is no reason why we should not also have Orchids many of which when in bloom are handsome, graceful, and beautiful. There is a charm even about the drooping spikes

of a well-grown plant of *Dendrochilum filiforme*, or *D. glumaceum* with its sweetly scented flowers. People, too, who see for the first time the large, waxy flowers of *Angraecum sesquipedale* are amazed at their singularity. *Odontoglossum Roezli* is graceful, whether in flower or not. In the cool Orchid house may be found *Odontoglossum* of wondrous beauty, and every good grower who has a fairly good collection of plants can always have plenty of bloom; what, too, is handsomer than that of *O. crispum* or *Pescatorei*? We have in our small house a good display in the way of flowers all the year round. Many Orchids will also last in bloom three months or more at a time. Will a Rose bush do this? A house may be kept well supplied with flowers all the year round from one set of Orchids, but this cannot be done with one set of Roses. In fact, I would go a long distance to see either a house well furnished with Roses in bloom, or the man who could show me one at the present time. "W." is wrong in saying that the culture of Orchids is now practically discontinued in the gardens of the wealthy, or at least is at a standstill. In short, he seems to be altogether on the wrong track.—J. D.

Greenhouse Orchids.—"Enquirer" asks what Orchids he can grow in his conservatory in summer, which has no shade except that which Vines afford. In winter the Vines rods, he says, are taken outside and the house is kept fairly warm. Under these conditions some of the Mexican *Laelias* would thrive if kept up near to the glass, and if air was freely admitted; such kinds as *autumnalis*, *anceps* and its varieties, *furfuracea*, *albida*, and *Epidendrum vitellinum* would succeed. In the same house, but not against the glass, *Odontoglossum grande* and *O. leopardinum*, *Lycaste Skinneri* and *L. Harrisonia*, *Cypripedium insigne*, *Cattleya Trianae*, and *Celoglyne cristata* would give satisfaction; these are all winter and spring-flowering kinds, and as the house in question is warm in winter, it would conduce to the opening of their flowers.

STOVE AND GREENHOUSE.

T. BAINES.

HOW TO GROW JASMINUM SAMBAC.

WHERE sweet-scented flowers are required in a cut state, no better plant can be found for supplying them than this Jasmine; they have, however, one fault, and that is they quickly drop after being gathered if great care be not used in handling them. If, however, they are cut with care and put at once into the positions which they are to occupy, their perfume and appearance are all that could be desired; no greenery beyond this Jasmine's own foliage is necessary to set off its pure white blossoms to advantage. When the plant gets sickly in appearance, which it does sometimes, the leaves turn yellow. In such a condition it does not grow freely, nor are its leaves then fit to mix with the flowers; this sickly character is often cured by allowing the plants to become dry at the root during summer, as being a vigorous grower it is a voracious feeder, and requires a large amount of water and stimulants to keep it in good condition when grown wholly in pots, particularly if of large size. It is not at all particular as to position, i.e., if it can have heat and moisture both at the root and overhead. It requires the heat of a stove to grow it well, and if planted out it should have its roots confined, as without this it would be likely to run too much to wood and leaves. We have it growing in a 12 inch pot, which stands on a slate stage over the top of the hot-water pipes; the stage is covered with gravel, and from this arises a moist warmth which no doubt assists growth considerably. The shoots are trained across the end of the house, whence they are allowed to cover a small part of the roof.

During winter it is kept drier at the roots than when active, and towards the end of January or early in February the branches are freely pruned into the older wood. It is then turned out of the pot, the old soil is partly shaken off—a difficult operation, owing to the mass of roots which it makes during the year. These are reduced, and it is then placed in the same pot out of which it was turned. For potting materials we use good turfy loam, a small portion of rotted leaves, and a free use of finely ground bones. The plant is then vigorously syringed twice a day, which keeps it quite clean; as soon as growth fairly commences it is freely watered, and when the pot is well filled with roots weak liquid manure is given each time it requires water, and an occasional sprinkle of bones is laid on the top of the soil, which greatly assists growth. Thus treated, it does not fail to produce flowers in abundance at the point of each shoot. It strikes freely from cuttings inserted in small pots and plunged in a moist bottom-heat; under such circumstances it quickly makes a sturdy plant if kept near the glass in the stove or in any other warm structure, and soon produces flowers in quantity. E. M.

Frost-bitten plants.—It is surprising how much frost it takes to kill plants if carefully thawed; if the heating apparatus is set to work and the house is made warm, a great many of the occupants that are frost-bitten will perish. But if even what are termed tender plants are thawed gently, they will revive. Our plan is, if any plant gets frost-bitten, to set it down on the floor or under the stage in the coldest part of the house, and to water it overhead with cold water; if the sun comes out, we shade the house at once. By adopting this plan in the case of *Pelargoniums* in pots in which the soil was frozen hard they revived, and did not show any ill-effects from being frozen. I would advise anyone into whose house frost has entered not to expel it hastily, for plant-life in many instances may be saved by means of careful thawing, even when the plants are given up as lost.—J. G., *Gosport*.

Two late-blooming Chrysanthemums.—Any *Chrysanthemum* calculated to lengthen the display made by these useful flowers should be prized and carefully attended to, for such kinds are not too numerous. Two sorts not generally well known to produce a late supply of flowers are *Zephyr* and *Golden Gem*. The first is a Japanese variety of medium size, having long, thread-like petals of the palest sulphur, a colour quite distinct from that of any other variety with which I am acquainted. The plant grows tall and in a natural manner; it blooms freely, but, like many other good kinds, does not produce cuttings plentifully. In fact, it is very shy in this respect. *Golden Gem*, lately exhibited by Mr. Owen, of Maidenhead, at South Kensington, and also at the National *Chrysanthemum Society's* mid-winter exhibition, and awarded a first-class certificate at each place, is a grand variety, raised between the Japanese and reflexed sections. It is branching in habit and flowers profusely. Its colour is a rich yellow, which deepens towards the centre. It blooms freely in small pots under good cultivation.—E. MOLYNEUX.

Marguerites in winter.—The large-flowered *Marguerites* are perpetual flowerers, and with but little attention may be had in bloom at any time. Having some fine plants of them covered with flowers and buds, we lifted them from the open ground and potted them before frost had affected them. They were treated exactly the same as ordinary *Chrysanthemums*, and they overcame the ordeal of lifting and root-breaking quite as well; in fact, but few plants overcome root-disturbance so soon as these do. Some very large plants were put in 12-inch pots, and although the leaves drooped for a few days, they soon resumed their usual healthy look. The flowers expanded freely, and have been most useful in a cut state ever since. They are, indeed, so useful in this respect, that anyone who has much cut-flower decoration to do can hardly be overdone with *Marguerites*.

The foliage, too, is excellent with which to dress small flower baskets or dishes. Marguerites are moderately hardy. We had fine bushes in this locality that survived several winters; but the last three have cleared all such plants in the open off.—J. G., *Gospport*.

WINTER HEATHS.

THE range of varieties of Heaths which flower during the autumn and winter is not wide, but what there are cannot be dispensed with where there is a great demand for flowers. The best autumn-flowering sorts are *hyemalis* and *gracilis*. The first-named is one of those which are known as soft-wooded Heaths, and it requires to be pruned rather severely after the flowering season is over—treatment quite the opposite to that required by the hard-wooded section, which flowers during summer. I may remark that *hyemalis* and *Willmoreana*, to which I shall refer presently, require more warmth than the other section. For this reason they should have less air than is given to the majority of Heaths, and if large healthy plants are required they must be kept under glass all the year round. I am aware that trade growers turn their stock into the open air during summer, and obtain satisfactory results; but for the most part they deal with young stock only, which is quite different from plants which have been exhausted by flowering, and whose growth has been cut back. Old plants I find it necessary to deal with liberally, and then I can ensure getting the season's shoots from 18 inches to 2 feet long, with a proportionate length of flowering wood upon them. As soon as these two sorts—*hyemalis* and *Willmoreana*—go out of flower, all the last year's growth should be cut back to within 1 inch of the old wood. The plants should then be placed in the warmest corner of the greenhouse, and should only receive just enough water to keep the soil moist. After they have rested a few weeks, they must be shifted into pots one size larger, until they reach pots 10 inches in diameter, in which they may be allowed to remain two years. Good peat and a fair sprinkle of silver sand are all that they want as regards soil; but it is necessary to pay particular attention to the drainage, for all Heaths are very impatient of water stagnating about their roots; indeed, I may say at once that careful watering and air-giving constitute the whole secret as regards managing these Heaths in a satisfactory manner. It is especially necessary to give water to the roots with care, from the time when the growth is cut down until active growth again commences, as during this period they cannot use up much moisture, and if they get an excess of it, mildew will attack the young growth as it appears. They should be allowed to remain in a close corner of the greenhouse until the young growth is 3 inches long. They may then be brought out to a lighter and more airy position, and during the summer months a thin shade should be put on the glass. During very hot weather they will require air both night and day, and plenty of it, and at the same time the root moisture will have to be increased. As a matter of fact, they will well repay for the most careful attention at all times; for until one has thoroughly tested the capability of the sort named *Willmoreana* to form large and handsome specimens, an idea cannot be formed of its value for that purpose. I have had this variety of Heath so large that it required two strong men to lift it. Such examples are valuable to cut from, and they make striking subjects during the months of January and February for the conservatory. Mildew sometimes attacks them; but if taken in time, it may be destroyed by dusting the affected part with sulphur. Other two varieties which I have grown for winter-flowering are *gracilis* and *melanthera*. The individual flowers of these are small, but they are produced in such numbers that a large plant is quite effective, when other flowers are less plentiful than they generally are in spring. For that reason, two or three large plants of each should be grown where winter flowers are required. Although these plants will

submit to pruning, and to be kept down to a small size, they do not take kindly to restrictive measures. In fact, if small plants are required, it is better to depend on young ones. Being more hardy than the other two I have mentioned, they may be grown with the hard-wooded section and treated in the same way, and after they have made their growth (which will be about the end of July) they may be set out of doors. Where one has to grow this class of Heaths along with a mixed collection of plants, they should have the coolest end of the house, as they only require sufficient fire-heat to keep them safe from frost.

J. C. C.

THE BEST BORONIAS.

THESE, as most of us know, are very ornamental greenhouse plants, furnished with good foliage and red, pink, or white flowers, which are produced during spring and early summer. They are easily grown, and well deserve more attention than they now-a-days receive. After flowering they should be cut back tolerably close; otherwise they are apt to become lanky and destitute of leaves at the base. *B. crenulata* and *B. serrulata* must, however, be made exceptions to this rule; they will simply require stopping, as they do not grow so vigorously, and are altogether more delicate, and, at the same time, more difficult to cultivate than other members of the genus. In potting, make the soil very firm, using good fibrous peat, broken up rather roughly, to which a good portion of sharp sand should be added; drain well, and water freely during the growing season. When growth is nearly finished, let them be well exposed to sun and air in order to thoroughly ripen the shoots, as it is upon the mature wood the flowers are produced in the following spring. Of the different kinds, *B. Drummondii* is a compact-growing and free-flowering species, the flowers of which are solitary and axillary, and produced in the greatest profusion. They are deep rosy pink, or red, and very fragrant. Of this there is a white variety the exact counterpart of the type. *B. elatior* is one of the largest flowered and best of the Boronias. It is a plant, too, very easily managed; it bears cutting well; indeed, it must be subjected to hard pruning after the flowering season if handsome plants of it are desired. The flowers, which are axillary and produced in profusion towards the upper part of the branches, are rosy purple and very showy. *B. megastigma* is a distinct and desirable Heath-like plant, not showy or ornamental, but indispensable on account of its delicate fragrance, which resembles that of Violets tinged with something aromatic. Its flowers, which are bell-shaped, are solitary, pendulous, and produced in abundance towards the points of all the branchlets; outside they are chocolate-coloured and yellow within. This plant should be grown in quantity, in order that sprays of it may be cut whenever sweet-scented flowers are required for bouquet-making or for apartments. With *B. pinnata* most of us are acquainted, and the same remark applies to *B. serrulata*. *B. crenulata* is somewhat similar to the last-named species, but is smaller growing. Its flowers are axillary and bright red.

W. H. G.

Chrysanthemum Sœur Melanie.—Those who have not grown this variety will do well to give it a trial during the coming season; either in the form of large or small plants it is almost unequalled for freedom of flowering. It is pure white, and an advantage it possesses over other kinds consists in the manner in which its flowers all open simultaneously, a grand property where cut flowers are wanted, as in many instances side buds must be sacrificed, the centre one generally opening some little time before the others. Capital plants about 2 feet high of this variety can be grown in 7 inch pots, with from six to ten spikes, each being furnished over a foot in length with blooms. Such plants are preferable to others more bushy in character. Bushy plants take up more room, and are not nearly so useful. Nothing can be better for filling jardinières at the foot of large mirrors than plants

grown like those just described. Any time during February is suitable for taking cuttings. Strike them in the usual way, either singly in small pots or three or four in larger ones. As soon as rooted, pinch out the point of each plant and place it at once in a cold frame, giving as much air as possible to keep all sturdy. If large plants are wanted, top the shoots once or twice more, pot on as required into the sized pots named, carefully and freely watering during the hot days in summer, as a loss of foliage disfigures the plants. No disbudding should be done; on the contrary, allow all on each stem to develop, as on that the peculiar beauty of this variety depends.—E. MOLYNEUX.

THE BRUGMANSIAS.

I HAVE long taken a special interest in these, partly from seeing some of them, notably *Knights*, bedded out many years since by my brother at Putteridgebury, and also from seeing some fine specimens in various conservatories, and having two fine plants under my care for many years. One of these is a fine plant of *B. suaveolens*, which was photographed some years since with three thousand blossoms expanded on it. The effect of the photograph was rather disappointing, the picture being spoiled by the sheer prodigality of bloom. The other is a plant of *B. sanguinea*, also of large size. I have also grown *B. Knights* well in pots and tubs, *B. arborea*, and the yellow variety of *suaveolens*, or *arborea*, as it was represented. It is impossible to exaggerate the grandeur and magnificence of these Brugmansias where lofty houses and sufficient area can be provided for them. The orange-scarlet variety differs widely from the others in not being fragrant, and in colour as well as form of the flower, which is more of an open-mouthed tube than a funnel-shaped bloom. Treated alike, and subjected to the same temperature, *B. sanguinea* is more of an autumnal and winter-blooming species; while *suaveolens* flowers three or more times throughout the summer and autumn, and then goes naturally to rest in a temperature of 40° or 45°. The *B. sanguinea*, on the contrary, flowers throughout the winter in this low temperature, though the colour is brighter and the flowers more numerous in 5° or 10° more heat. It is, however, considerably hardier than *suaveolens*, though both thrive well in the coolest greenhouse from which frost is merely excluded in winter—the red one flowering, the white one resting, during the cold season. Both also submit to severe pruning work, which is fortunate, as otherwise there are few glass-houses in private gardens that one or a couple of Brugmansias would not fill to severe overcrowding.

I very much doubt if *B. flava* is a sport from *sanguinea*, as the flower is nearer that of *arborea*, and unless I am much mistaken (I do not grow it now) also fragrant; *B. Knights*, the only double or hose-in-hose Brugmansia I have grown, judged by its fragrance, is also a distinct species, as the scent is totally different from (and with a spicy addition to) either *arborea* or *suaveolens*. The latter is also different, and has a much fuller fragrance than *arborea*. They are both so far alike in this that neither has much scent at noon, and both reach their maximum fragrance at midnight. About 6 p.m. and 6 a.m. the scent of Brugmansia *suaveolens* reaches to about half its intensity; from 6 p.m. to midnight it waxes to its maximum force, and from 6 a.m. it wanes to nil at mid-day.

These curious facts add to the interest of growing these magnificent trumpet flowers. At various times our lofty orangery here has been lighted up to bring out these interesting features, and enable evening parties to test and enjoy them. On several occasions also, when *B. suaveolens* has been in full flower and robust growth, the odour has been distinctly tasted, and more rarely seen in the form of a thin phosphorescent light passing like a vapour from the throats and mouths of the open tubes. On these occasions the whole house, a long corridor, and the mansion attached have been filled and permeated with the perfume,

which only the few who can revel amid the most powerful, though exquisitely sweet, odours can enjoy. Those who have been partially overpowered or become drowsy under the fragrance, have had the consolation of a long respite of any excess from six in the morning to six at night. Thus the intermittent quality of the fragrance of *Brugmansia suaveolens* enables many to enjoy the beauty of these plants who could not do so were they always and at all times equally fragrant.

Brugmansia blooms of the *suaveolens* type grown in Scotland must have greatly extended their staying properties over those grown in England if the following statement may be relied on. No flower can equal this white *Brugmansia* for purity and fragrance, and for room or church decoration it is unequalled, as if gathered before the blooms are quite expanded they last a long time in perfection. The words I have italicised are the reverse of true in England, unless with the single exception of *B. sanguinea*, the flowers of which will last a week or more without fading. The so-called double, that is, the *Hose in-hose B. Knighti*, has also considerable staying power, but it suddenly loses its whiteness often, though it may not fade. But *suaveolens*, if cut too soon, looks wrinkled before it opens, often refuses to open afterwards, and when it does open, or when cut fully opened, it seldom lasts more than six hours at the longest, even when the end of the flower-tube and not the stalk only is thrust into water.

Possibly the less exciting climate of Scotland may add somewhat to the longevity of these evanescent flowers. I have often observed that the late flowers last longer than the first or second ones in June or August. But so fragile are the individual blooms of *Brugmansia suaveolens*, that large vases and baskets have often had to be filled with them in the drawing-room just as the guests were leaving the dining-room, in order that they might keep fresh for the two or three hours remaining of the evening. And as for church decoration, they would all be down in the south before the parson got to the sermon, and would form an apt illustrated text of the fragility of life.

HORTIC.

SEASONABLE WORK IN PLANT HOUSES.

STOVE.—In determining the time of starting some of the most important spring and summer-flowering plants there are several things that require to be considered, not the least of which is the character of the houses in which the plants are to be grown. In modern, well-constructed, span-roofed houses that admit a maximum amount of light, and that stand in a position where there are no external influences calculated to obstruct this all-important element, it is obvious that a start may be safely made considerably earlier in the season than where the plants are located in old-fashioned, heavy, lean-to structures, where little light reaches them until the sun has gained more force, and in the case of plants that are wanting in vigour, or that have not had their last season's growth well matured, it is not advisable to excite them early, as they are wanting in the first essential to enable them to flower early. The advantages attendant on getting such of the spring and summer-flowering kinds as *Allamandas*, *Bougainvilleas*, shrubby *Clerodendrons*, *Dipladenias*, *Tabernaemontanas*, *Gardenias*, and the like to move early are that they afford a proportionately longer succession of flower or bloom oftener before the dormant season again comes round. Where the conditions above indicated are favourable, the temperature may shortly be raised a few degrees above what it has been kept at whilst the plants were at rest. This will be found better than sudden excitement by a greater rise all at once.

GARDENIAS.—The flowers of these plants are held in such estimation by some, that a supply is required during as much of the year as it can be had. Yet even where a large stock is grown, with means of giving it plenty of heat, it is difficult to get the flowers to open during the

depth of winter, as the buds, however forward they may have been in the autumn, move slowly in the absence of sun-heat. The plants that have their buds the most prominent should be placed at the warmest end of the stove and well up to the glass. Keep the soil moderately moist—not too wet—as comparatively little root action will now be going on, and if too much water is given, the buds will be likely to drop rather than come to maturity. It is not advisable to syringe the plants overhead at this time of the year, as it not unusually happens that the buds fall if much moisture hangs about them. One of the worst evils to contend with in the cultivation of these plants is that where mealy bug exists, so partial is this insect to them, that it gives much trouble.

BOUARDIAS.—The difficulty that exists in getting cuttings of *Bouvardias* to root when made from shoots that have been grown in the way that most things succeed under induced growers of these plants to resort to propagating them from root cuttings, a process that will generally answer for any plant which there is a difficulty in increasing. But it is found that if the old plants that are to produce cuttings are dried off for a few weeks, so as to stop growth and cause the leaves to fall, the young shoots produced in a genial temperature after the branches have been cut back and the roots well moistened will root as readily as those of a *Fuchsia* if taken off with a heel. Stock plants that during the latter part of autumn have been treated in this way will shortly furnish an abundance of cuttings, as almost all the eyes start immediately the plants are subjected to heat and moisture. When the shoots are about 2 inches long they are in a condition to strike; they will root readily in ordinary stove heat, kept moist and close. No time should be lost in getting the requisite quantity going, as, unless the young plants are well established early in the year, they do not attain the necessary size and strength before autumn to enable them to produce a full crop of flowers. It is well to bear in mind that strong, vigorous examples yield finer heads of bloom, and many more of them, than the ordinary-sized plants usually met with. Independent of the value of *Bouvardias* for stove and warm conservatory decoration during autumn and winter, few things equal them for giving a continuous succession of flowers for cutting. Their profuse habit of blooming, purity of colour in the flowers, and agreeable fragrance of some are such as to make them worthy of a place in the most select company.

SOLANUMS.—*S. capsicastrum* and *S. pseudo-capsicum* are not surpassed by any of the small-growing berry-bearing plants for general usefulness in the various ways in which they can be made to do duty, being alike adapted for room or hall decoration, or for associating with flowering plants in greenhouses and conservatories during the autumn and winter. Cuttings need to be struck early where the plants are wanted to be in condition for use in the autumn. If the stock has not already been propagated, no time must be lost in putting in the cuttings; these should consist of the points of the shoots such as are generally to be had from plants that have ripened their crop of berries during the later months of the past year. They will root in two or three weeks if placed in genial heat and kept moist and close, after which put them singly into small pots, pinch out the points of the shoots as soon as growth commences with a view to make them branch out at the base, without which they have a straggling, unsightly appearance. Cuttings should only be taken from those plants that show a disposition to produce their berries freely, as there is much difference amongst seedlings in this respect. The young stock must be kept on growing in a genial temperature until spring, after which the sun will afford enough warmth.

FITONIAS.—These plants are so accommodating that they will thrive when overhung by other things to an extent that would cause many to fail. In no way are they seen to better advantage than when used as an edging to the side stages, or for a

covering to the stages of a stove as a setting wherein to stand other plants. They will grow in almost any material that water will pass readily through; if shell gravel or ordinary fine sandy gravel is used on the stages they will grow freely in this, provided they are not allowed to get dry at the roots. Cuttings put in now will strike in little time by keeping them warm and moist; when rooted they can be planted in the way indicated, or grown in shallow pans and set about amongst the pots containing larger growing things; in this way less bare surface of the stages is seen.

PANTUM VARIEGATUM.—This pretty free-growing plant can be used similarly to the preceding. It makes one of the best of all edgings in a stove, and is alike adapted for draping hanging-baskets containing flowering plants. Young stock, such as that struck from cuttings put in now, is the most suitable for use in the manner just mentioned, and in various other ways this useful drooping plant can be employed. Heat, moisture, and a confined atmosphere are the conditions under which this plant strikes quickest.

CISSUS DISCOLOR and *C. PORPHYROPHYLLUS* are amongst the best plants that can be used for occupying bare places on back walls, or for use where free, quick-growing subjects of drooping habit are required. Cuttings of the young half-ripened shoots will root with ordinary treatment in two or three weeks, when they can be potted on preparatory to their being placed where they are to be grown. It is well to push on the propagation of these and other things that are alike easily struck before the busy time for general cutting-striking comes on, when attention and room will be wanted for a host of other subjects.

INSECTS.—Those who have to deal with a general collection of stove plants need to be ever on the look-out for the various insects, that are more persistent in their attacks consequent on their increase being quicker in the genial atmosphere of a warm stove than in structures where a lower temperature is maintained; if there is one thing more than another that it is well to impress upon those whose experience in plant-growing is limited, it is that those who keep their plants the freest from insects—other details of cultivation being fairly well carried out—are certain to be the most successful, as, where insects are allowed to get numerous, it is impossible for the plants they affect to thrive as they should do. As soon as the sun gets more power, so as to run up the temperature of the stove, insects of all kinds that are present begin to increase apace. To limit this as far as possible all the stock should be closely looked over, and any that are affected ought to be carefully gone over, and dipped, syringed, or sponged according to the nature of the plants and the kinds of insects that affect them. Whatever time is occupied in this work at the present season will be well spent, and will save much labour later on.

GREENHOUSE.—The early-blooming varieties of the large-flowered section of *Pelargoniums* are much the best to grow for those whose object is to have a good display early in the season, as they come in at a time when indoor flowers almost alone have to be depended on. If the stock was got on with early in the autumn by having the plants well established in the pots in which they were intended to flower before the growing season was too far advanced, and they have up to this time been kept in a warm greenhouse temperature, they will now be showing their flower-heads. The varieties in question are naturally dwarf, compact growers, the wood being remarkably short-jointed, so that when kept well up to the glass the shoots do not get at all drawn, even when subjected to more heat than is usually looked upon as sufficient for *Pelargoniums*. As soon as the flower-heads have made a little progress, manure water may be given once a fortnight or so, applying it oftener later on when more progress has been made.

CINERARIAS.—The earliest portion of the stock will now be blooming. Where the successional plants have been well cared for the balls will be a

complete mass of roots, and they will require regular applications of manure water, which will increase the size and substance of the flowers. The whole of the stock should be frequently examined to see that it is quite free from aphides, to which Cinerarias are more than most things subject, and if not kept quite clear from them, they become a fertile source from which all other plants associated with them, on which the insects will live, get affected.

ROSE GARDEN.

CLIMBING AND OTHER ROSES.

How to have Roses in bloom for as long a portion of the year as possible, and in all sorts of positions, is a matter worth serious consideration. There are two classes of Rose growers, besides those who grow for sale; the one has for its principal object the production of blooms for exhibition, while the other grows them for

are not at all particular in the matter of soil, being able to thrive and grow in that of almost any description, although, of course, they thrive best where the soil is good. Where the best kinds of continuous-blooming Roses are required to thrive and repay the cultivator, there the soil must either be naturally good, or adapted to the purpose by artificial means.

For poles, pillars, arches, arbours, walls, sides of houses, and high buildings, &c., only those Roses are suitable which have more or less of what is called a climbing habit of growth. Roses which make long rambling growths, whose shoots are unable to stand up without support of some kind, these are the kinds which do duty as climbers; before determining on the kind of climber to plant, however, the height the plants are required to attain must be considered. Most of the vigorous Hybrid Perpetuals and Teas may be relied on from 8 feet to 15 feet if the soil be good, and on warm sheltered walls 4 feet or 5 feet higher. The extra strong growers of the same

in good and deep soils they would climb in a very few seasons, if well tended, any ordinary church steeple. They completely cover themselves with blooms during the blooming period if rightly treated, and all the treatment they require, if in good soil, consists in tying them to their supports, pruning out weak and exhausted wood, and encouraging to the utmost such vigorous young shoots as may be required. No growths need be shortened except to keep them within the bounds allotted to the plant, and to take off unripened ends. Climbing Roses away from walls should not be planted in very exposed positions, or, as a rule, they will fail to gratify the cultivator.

Climbing Roses may be used to screen unsightly buildings and other objects, by training them to galvanised wire or other fences or supports, and, except when the leaves are off, answer this purpose most admirably, by the interposition of their loveliness. All the above methods of growing Roses not only yield good decorative effects, but give supplies of flowers for cutting. Heretofore, however, I have not mentioned Moss Roses, because, from a decorative point of view, in the outdoor garden, as growing plants, their value is comparatively small. As cut flowers, however, they are among the most exquisite of Flora's productions. J. E.

SNOW AMONG THE ROSES.

So far the snow has probably done good, and not harm, to the Roses. Here and there it has rent off a bough from tall standard bushes or pyramids, and in a few instances has broken down some dense dwarf. But, as a rule, Roses have either carried their snow burdens in safety, or bent down beneath their load without breaking. The very tenacity with which the successive falls of snow cling to the Roses also afforded them very substantial protection against the severe frosts that have succeeded them; while dwarf Roses under the snow have been safe from all harm from any amount of cold. This has been a decided gain, with the thermometer getting within close reach of zero on several occasions. A good many old-fashioned cultivators hold that snow is not only a protection, but a manure. And no doubt it does collect from the air and deposit on the surface a sensible amount of ammonia and other manurial matters or gases. But it is often somewhat difficult to distinguish in practice between the effects of protection and food. It is held correctly that in the feeding of animals a certain amount of warmth is equivalent to a given amount of food, and it seems also certain that the same law of equivalents holds good among such plants as Roses. The direct result of starvation from cold does not vary greatly from that arising from lack of food. Weakness, partial paralysis of function, sluggishness of movement, ending in a stoppage of circulation of fluids and death, follow in both cases alike—whether from identical causes or not is hardly material to our argument. What is very material to us, as rosarians, is the fact that the snow is favourable to our Roses. It conserves their heat, and, maybe, augments their food supplies; while, in so far as it does the former, it enables them also to dispose of more food to better purpose. The growth, vigour, and beauty of Roses are very much as the heat that they are subjected to or have at their disposal. It is therefore a clear gain for our Roses when, instead of being exposed to 20° or 30° of frost, the snow keeps them in a snug, warm atmosphere of from 2° to 4° of frost only, or even less.

Possibly not a few answer, that if the growing season proves genial, it matters little or nothing to the Roses how much cold they are exposed to in the dormant season. But every day's additional experience convinces us that this is a great mistake. For, first of all, there is no dormant season among Roses. The phrase never meant as much as many put into it. There is no such thing as entire cessation of root-growth among

Rose arches in Achareidh Gardens, Naim. Engraved for THE GARDEN from a photograph.

decoration and the production of flowers for cutting. Now there are so many families of the Rose, and so many varieties belonging to each family, that suitable Roses may be found for almost all kinds of uses and positions in a garden where flowers of any kind can be used. The following are some of the uses to and positions in which Rose plants may be put in a garden, viz., beds, borders, shrubberies, poles and pillars, arches, arbours, walls (north, south, east, or west), hedges, screens, &c. Before entering into any particulars, however, as to the different kinds of Roses adapted to the various purposes just mentioned, I should like to make a few remarks on the more or less important subject of soil. I say "more or less" here, because if only the commoner kinds of Roses be grown, the kind of soil is a matter of small importance. The old summer-blooming climbing Roses belonging to the Boursault, Ayrshire, and sempervirens classes, as well as most of the varieties belonging to the Gallica, Hybrid China, Hybrid Bourbon, Austrian Brier, and many other summer-blooming families

classes, with the Noisettes and Hybrid Noisettes, will cover well up to 15 ft. or 20 ft. or more. The Banksian Roses are excellent as climbers, but should only be planted against walls in rather sheltered positions; they are only summer bloomers. The white and yellow may be both relied on up to 30 ft. in good soil, but the large white will run much higher. This kind is evergreen, except in very sharp winters, which is a great recommendation, but it is not so prolific in its blooming qualities as the two first-named varieties. The old Blush and Crimson China Roses will also run up the face of a wall freely to a height of 30 feet, and, as before stated, for continuous-blooming qualities they are unsurpassed by the varieties of any other family of Roses; indeed, they are frequently out at their best when inexorable frost sternly interposes and checks them; in spite of this however, it is not unusual to find a few buds still unfolding at Christmas time. The old-fashioned summer-blooming Roses before alluded to are capable of almost anything in the way of height; probably

Roses, unless their fluids are converted into solid ice. Complete dormancy, stagnation, rest never did exist among Roses. But there is less of it among them to-day than ever there was before. More ever-growing, ever-blooming blood has been poured into them from the Noisettes, Chinas, Teas, till the great class of Hybrid Perpetuals and others have become less restful than ever at any season. Though all too few of our Roses are ever-blooming in our climate, the majority of them are ever-growing, and the more active their growth, the more serious is the danger to which they are exposed.

Now, experience proves that our Roses in the main are quite safe when buried in snow. The snow temperature, say a few degrees either side of 30° Fahrenheit, is one of the very best for the safe keeping of Roses during the winter season. The snow temperature is not only safe, but equable. In fact, it is the latter quality that constitutes the main element of its safety. It is less the absolute severity of the cold that mars and maims our Roses than the sudden changes, often amounting to 15°, 20°, or more in a few hours. The mere mechanical effects of such sudden freezings and thawings prove most trying and destructive. The ratio of destruction also rises with the suddenness of the changes. Now, the snow lies between our Roses and violent and sudden changes, and this forms a compound barrier between them and harm.

It will, therefore, probably be found that, in contrast to the violent injury inflicted on trees and shrubs, the snow has been of real service to our Roses. With or without other protection it has saved our dwarf Teas or others from the risks and dangers of 20° and 25° of frost, and done much to carry standards safely through the same ordeal, by wrapping every twig and bough round with a snowy covering, almost sufficiently thick to keep their temperature at the snow average. Seldom have successive snowflakes elung to vegetation as they have this winter, and in their close sticking to our Roses they have doubtless saved the majority of them. Of course, the snow has adhered with many times multiplied volume and mass where our early advice to thrust a handful of Braeken fronds into the heads of standards was adopted. In all such examples the Braeken was thatched with about a foot of snow, the whole being impenetrable to any amount of cold possible to our climate. D. T. F.

FRUIT GARDEN.

W. COLEMAN.

BLenheim ORANGE APPLE.

WHEN a few weeks ago I forwarded to you half-a-dozen good fruit of this useful variety I stated that they were not the finest or best coloured examples grown by Mr. Phelps, of Tibberton, near Gloucester, last year. Quite recently I have received from that grower one of his very best fruits, unquestionably the finest I have yet met with, and in response to an application from Mr. Van Deman, pomologist to the American Government, I have forwarded it to Washington for examination and comparison. The Apples in question, from standard trees nearly forty years old, did not create any great degree of surprise when shown by Mr. Phelps at Gloucester in November last, as other exhibitors with wonderful fruit have been in the habit of competing with him for years. Indeed, the classes which these exhibitors—farmers, it must be understood—are capable of filling up prove beyond cavil or question that private enterprise without the aid of Government or Royal Horticultural Societies can and will restore our much-abused orchards to the position which our climate fits them to occupy. What one, nay a dozen, men residing in the vale of Severn can do, others living in warmer districts may also do equally well, and possibly better, if they will only put their brains to work and their

shoulders to the wheel. It is all very well for one section of our leaders to call upon Jupiter, and for another to cry over spilt milk, but neither of these will put us in the way of growing large, rosy, luscious fruit infinitely superior to the handsome specimens imported from Canada and other parts of the globe. What we require is perseverance and common sense on the part of occupiers and encouragement from the owners of the soil. The latter, no doubt, are willing, but hitherto, with few exceptions, the matter has not been placed before them, and a great number are still ignorant of the fact that first-class Apple orchards will enable the farmer to live where corn does not pay for the tillage of the ground.

We cannot expect all landowners to go into the matter as Lord Sudeley has done, but the majority might follow the Madresfield Court system of devoting a piece of suitable ground to the working and raising of the best sorts of Apples, Pears, and Plums for distribution amongst the tenants. In several places I have seen this work managed, or mismanaged, by the woodman or forester; and in nine cases out of ten, hard, wretched, crooked stocks, with stunted heads, have shown that the attempt has turned out to be a failure. Clever men, like Mr. Webster, and a host of professional foresters, who have been thoroughly trained in nursery work, can, of course raise, select, and work stocks quite as well as operators in the trade, but a great number of hard-working honest men, who live and die on one small estate, cannot be expected to turn out trees that will be of use to the rising generation. Nay, more; many of them consider this branch quite extraneous to their legitimate calling. Aware of this, Lord Beauchamp very wisely placed a piece of land, close to the kitchen garden, under the management of the late Mr. Cox, shortly before he died, and Mr. Crump, his successor, has carried on the work ever since. In this nursery all the leading sorts of vintage and pot Apples which do well on his lordship's estate are grown, and grown well, and it is needless to say that the farmers who can have them for planting out are not the only individuals who derive benefit from the arrangement. The farmers on this estate are treated in a similar way; and, although modest individuals shrink from boasting of their home work, I may say that one occupier sometimes makes 400 hogs-heads of cider in a good season, and more than clears his half-year's rent by it. Horticulturists generally, and people who read the horticultural journals, know that a long pull, a strong pull, and a pull altogether is now needed, otherwise the ball recently set moving will not carry us to the front, but this position must be attained before we can compete with our colonial relations. The orchards in America only a few years ago were in a plight similar to our own, but the owners and occupiers have gone ahead, and we must be content to follow in their footsteps.

I commenced this paper with Blenheims—on the brain, some may say. Possibly so. I do not wish them removed, for this Woodstock, Northwick, or Kempster's Pippin is a noble Apple, and I will close my remarks by informing a correspondent that I see no reason why the wish he expressed a few weeks ago should not be fulfilled. In THE GARDEN, I forget the date, he said he should dearly like to see a good orchard composed entirely of Blenheims in full bearing at least once in his lifetime. If he has not passed the jubilee of his birth, and can command a few acres of upland rolling ground on the old red sandstone or marl, he should lose no time in trenching 2 feet to 3 feet deep, and planting clean, healthy standards 30 feet apart and 30 feet from row to row. Blenheims are impatient of

the knife and do not bear well when young, but when allowed an abundance of room for the full development of the strong branches and exposure of the fruit to sun and air, healthy trees after a few years' growth produce regular and abundant crops annually. Although this variety is not considered suitable for restrictive training in small gardens, I have seen it bearing well as a horizontal espalier on the Paradise stock, but it is short-lived and soon shows a disposition to canker. For this kind of work fortunately the names of suitable sorts are numerous enough, and as the Blenheim delights in a deep, but well-drained soil and plenty of head room, the orchard unquestionably is the proper place for it. When planted singly or a good distance apart, the branches often assume a horizontal or drooping habit, but planted thickly they attain a great height, and then fruit from the centres and lower branches is spotted and deficient in colour. We have at this place a double row of some twenty trees planted in this way. They are now little short of 50 feet in height, and, judging from their size and general appearance, one may readily suppose that they were planted before the Blenheim Pippin found a place in nurserymen's catalogues.

OUTDOOR GRAPES.

IN THE GARDEN for January 1, p. 3, "W. R." says he has seen "many little Kent and Surrey gardens during the past few years, and never saw a really good Grape; but it is extremely rare to find that any attention is given to the Vines." Exactly so; negligence or inattention generally results in failure, and deservedly so. Even at Thomery, where the sun-heat in spring and summer is far in excess of that which we obtain in England, the greatest care and precautions must be taken to make Grape culture a success. From Mr. W. Robinson's book, "The Parks and Gardens of Paris," I take the following extracts. On p. 378 he begins the chapter on "the culture of the Vine at Thomery," with this remarkable and enthusiastic view of outdoor Grape culture in England—

As it is certain that the culture of the Grape grown against walls in the open air may be attempted with profit over a large part of the southern and midland counties of England, an account is given of the successful and highly interesting culture of the Chasselas Grape near Paris, where it must be growing against walls as well as with us.

Again, on p. 380, he tells us that—

Grape culture is often successful against houses with us (i.e., in England) when it receives more chance attention from so-farthers and others. By selecting the soil and position, and really paying some attention to protecting and cultivating the Vine, we may grow good Grapes against walls, even in many places where ground vinerias are now resorted to. Should any person doubt the possibility of cultivating the Chasselas and others of our best hardy Grapes in the open air, I merely refer him to the horticultural papers for the autumn of 1868. They contain abundant evidence that even with the rough treatment Grapes now receive in the open air it is quite possible to grow them of good quality on walls. Grapes are already grown well in the open air in a few places—by Mr. Durkin at Bury St. Edmunds, for example, and by Mr. Fenn in the Rectory Garden at Woodstock—so that there can be no doubt about the possibility of ripening good Grapes over a considerable portion of England and Ireland. It is necessary to observe that the plan is only recommended for warm soils and positions, for gardens not having much glass and yet some wall space, for covering cottages, out-offices, &c., and not in any way as a substitute for Vine culture indoors.

Comment on the above is needless.

VERONICA.

* The question is, what are the chances of outdoor Grape culture in England, and not what anyone said of it years ago. Having written these words, and looked in vain since in some of our warmest counties for eatable Grapes in the open air, is surely no reason for keeping to them. And when men like Mr. Marnock tell one of having passed through the same hopeful stage, and then tried experiments and failed, there is surely good reason for doubt. Mr. Cornhill sends me a long article explaining the conditions under which outdoor Grape culture was carried on successfully in his youth. Few of us who have

thought of the matter, could not do the same thing, but there is no doubt that the youthful taste about fruit is not over-particular, and the ease with which the finest Grapes may be grown in many kinds of cheap glass structures makes the comparison for the outdoor Grape much more severe than it was twenty years ago. The price, too, at which fine Grapes are now sold in the market is very low. As to the question of profit, the case is hopeless, because good Grapes have frequently been sold in Covent Garden this year at a much lower rate per pound than good hardy fruit fetches. Then, again, a great area of country with a fine climate for Grape-growing, such as Madeira, is sending us a supply of outdoor Grapes—a supply which we may look to increase every year, as the many sunny hills in Spain, Portugal, and Italy, and other countries begin to be devoted to Grape-growing. Assuming that, for other reasons, the thing is worth attempting, if anybody can suggest how, by the offering of prizes or otherwise, Grape culture can be practically tested, I shall be happy to carry it out, or support a reasonable scheme; but I will print no more articles on the subject, except suggestions how to test the matter fairly, should such come.

W. R.

LANCASHIRE GOOSEBERRIES.

A FRUIT-TREE grower informed me the other day that the large sorts of Lancashire Gooseberries are getting into demand in other parts of the country, and probably for dessert purposes. He made particular mention of Careless, white, very fine; Eskender Bey, red, large and fine; King of Trumps, white, very large; Melbourne Red, large; Snowball, white; Alma, white, very large; Crown Bob, red; Plunder, white, large; Major Dibbert, red; Monarch, red, large; Weasel, white, very fine; Roaring Lion, red; Wilmot's Early Red; Troubler, green; Superior, green; Rough Red; and Lancashire Lass, white. It would probably not be difficult to make up fully 150 varieties at least of exhibition Gooseberries.

An old and successful grower was once asked what is the best compost to grow these fine Gooseberries in, and he said the best was the top spit of an old pasture, mellowed by lying by for twelve or eighteen months; further, he recommended that they should be planted to the depth of 4 inches to 5 inches, but opinions differ on this point, some planting rather shallower. The best time to plant is in the middle of October, or as soon after as it can be done. An old grower in Lancashire once told me that he had grown Gooseberries in his garden for nearly fifty years, and that when he planted a new tree he dug out the old soil to the depth of half a yard and about 4 feet square, and filled in the space with clods he had had by him for a year, turning them over once a month or so before using them. And he further stated that he prepared his plant for planting in this way: he pruned his plant, leaving the shoots 6 inches long, and carefully removed all the bottom buds by means of a sharp knife, taking care not to damage the stem; then he placed his plant in the centre of the prepared space and covered the roots to the depth of about 2 inches. The tree is then left until the beginning of February, when a good mulching of decayed cow manure laid by for a year or more is laid on the surface to the depth of 3 inches, a little road sand being added. The manure is allowed to lie in pieces about the size of a large egg until the middle of April, when it is beaten fine, and a little new soil added to the surface, doing this generally after a shower of rain.

Now as the object of this method of culture is to get large Gooseberries for show purposes, so about the middle of May, when the plants are in blossom, only one is allowed to remain where two or more are found in a cluster; and if they are so close together that when developed one is likely to injure the other, one is removed in June, that is, if the fruit promises to attain a good size, but not without. This, at least, is what some do. If during June and July the sun shines out very warm, the trees are shaded from the sun,

a light material being placed over them, about 2 feet above the branches, so that the air can circulate freely underneath, which is considered to be a matter of great importance in the fine development of the fruit. As a matter of course no weeds are allowed to grow on the surface, and caterpillars receive a very short shrift if they put in an appearance. About the beginning of August the fruit is ripe and fit for exhibition.

Pruning the trees is a matter of considerable importance in the matter of exhibition Gooseberries. Of necessity a material difference has to be observed in the pruning of those trees on which it is intended to grow show fruit, and those from which fruits for the dessert or culinary purposes only are required. Not nearly so much wood is left upon the former as upon the latter. Indeed, where large fruit is required no weak shoots whatever are allowed to remain upon the tree, and the strongest are shortened back to within 5 inches or 6 inches of the wood of the previous year's growth. The superabundant shoots should be taken off in such a manner as that the strong ones are left at regular distances from each other. And if of these many are suffered to remain, the tree becomes overcrowded with foliage and new wood, and the fruit is deprived of the needful amount of light and air.

Show Gooseberry trees are generally trained and pruned horizontally, and this form is advantageous, inasmuch as the fruit hangs clear of the branches, and is consequently not liable to be bruised, which would be the case if it were grown upon upright branches. On the other hand, Gooseberry trees bearing fruit required only for ordinary culinary and dessert purposes merely require thinning and to be trimmed into a suitable shape—say hemispherical. But the pruner should never forget that light and air are primary agents in the production of good fruit, and that unless the branches be kept at such distances from each other as will allow, when the branches are fully formed, of the complete exposure of the berries to their influence, the crop will be inferior in quality and insignificant in quantity. And while thinning, the operator should in all cases prune to an outside bud, and should not cut all the shoots clean off, but leave about half an inch at the bottom to form what are called "fruiting spurs," by which means considerably more fruit will be produced. In Cheshire, I have seen vessels of water placed just under the hanging berries of large exhibition Gooseberries, it being supposed they absorbed moisture in this way, and so increased in size.

R. D.

SEASONABLE WORK AMONG FRUITS.

CUCUMBERS.

THE past month has been the reverse of favourable to winter plants holding their own, but we may hope the most trying storm experienced for some years is now nearly spent, and brighter as well as longer days will speedily dawn. The great drawback to progress is dry fire-heat, of which we have had more than enough, as it not only paralyses the plants, but invariably leaves a legacy of spider and thrips to prey upon them when, through want of light and invigorating air, they are least able to withstand their enervating attacks. Good covering, to which I have often directed attention, this winter has been a great help in protecting the glass from the chilling effect of repeated falls of snow; as well as in keeping in a great deal of warmth and moisture. But covering alone will not suffice; we must have materials for producing a steady supply of moist heat, and I question if there is anything equal to sound fermenting Oak leaves. These we use extensively all the year round, and renovate the beds whenever we find the bottom-heat falling below 80°. By adopting this means of charging the atmosphere, and by giving the roots plenty of water, our plants have grown freely down to the present time, and although the syringe has been banished since November they are quite free from insects, and will give a good return now fruit is becoming valuable. The old foliage has not been removed,

as an indifferent leaf hitherto has been of use, but the time is now at hand for taking them out gradually to make room for the young growths, which, by the way, will not be pinched until the middle of February. When pinching is resumed, the syringe will be used for damping the walls and other surfaces, but avoiding the pipes when heated, and for dewing over the foliage about 1 p.m. on bright sunny days. The top heat at the present time ranges from 65 at night to 75 by day, or perhaps a few degrees lower when days are dark and nights unusually cold. These temporary depressions do not, however, seriously affect the plants so long as the roots are kept in a satisfactory condition; indeed, it is better to start in the autumn with heats that can be maintained throughout the winter than to dash into the tropics at the outset and allow the roots to canker and perish in a low bottom-heat at Christmas.

Top-dressing, as I have often advised, should be kept in a dry, warm place ready for use at all times, little and often, as the roots show upon the surface. As days increase in length and external conditions become more favourable to growth, both of roots and Vines, the material used may be somewhat heavier and richer than that applied before the turn of the year, but solid manure in any shape, even as a mulch, if possible should be avoided. Some Cucumber growers recommend the use of large percentages of manures, not only as mulches, but also for mixing with the compost, and, to the best of my belief, lure many an unfortunate follower to grief, as there exists but little doubt that gross food, in winter especially, is one of the principal causes of sudden collapse. I could name a noted place where, forty years ago, nothing but pure mountain turf chopped into small cubes and packed on the surface like paving stones was introduced all the year round. Liquid manure well diluted was freely used, and the plants, Lord Kenyon's Favourite, remained healthy and prodigiously fruitful from year's end to year's end. This practical proof satisfied me that manure in the solid should have a wide berth, but all growers cannot obtain mountain turf, consequently they must manufacture a substitute, and this they can readily secure by taking very thin sods from an old sheep pasture—if on the red sandstone so much the better—and adding one-third of rough charcoal, a like quantity of old plaster or lime rubble, and a little root to destroy wireworm. When these materials, stacked in layers, have lain a few weeks they may be chopped down, well warmed, and used for potting or top-dressing. Heavy loams may be improved by the addition of a little turfy peat, and poor soils by a dash of bone-dust.

Detailed management.—If the plants were not put out too early, growth has been steady, and the Vines are well furnished with clean, healthy foliage, more than half the battle is already won; but a vigilant eye must still be kept on them, or rather their enemies, whose name is legion. Thrips can be destroyed by Tobacco smoke, but its introduction is rather dangerous, and for this reason the foliage should be quite dry when the fumigator is set in motion. Spider may be checked, if not annihilated, by repeated syringings with soap water, or a very mild solution of Gishurst compound; but next to good culture, if taken in time, there is nothing more effectual than careful band-sponging. Mildew disappears under the influence of sulphur, which can be applied as a wash, or in a dry state dusted over the parts affected; and canker may be checked by the application of quicklime, rubbed into the sores, combined with improved ventilation. When the plants show signs of free growth, the young shoots should be regularly trained over the wires, and allowed to carry a moderate crop of fruit, all imperfect "shows" and male blossoms being rubbed off in their infancy. I never fertilise in the depth of winter and find the fruit on healthy plants set and swell well without the aid of male flowers, which, left in abundance, naturally weaken the plants. If the latter are growing in pots, it is a good plan to pack large pieces of light turf round

the rims, and fill in the centres with the roughest of the top-dressing, to draw out stem roots, and to repeat this operation as often as they find their way to the surface. In this way a new set of roots can soon be formed, and being free from confinement, the plants push vigorously, showing fruit at every joint.

Spring plants.—After putting out the best autumn plants I generally make a point of reserving a few of the latest which many would throw away. These in 9 inch pots are plunged overhead in warm leaves in an intermediate pit, and allowed to rough it through the dead months; if they survive, the addition of fresh fermenting material induces a start in February, and we find them useful stop-gaps later on, as they enable us to cut over a house long before spring-sown plants come into bearing. Where this link does not exist, young plants from seeds sown in December should be worked on as rapidly as possible, especially if winter fruiters are not looking quite satisfactory. I have often pointed out that the earliest Cucumbers and Melons may be raised side by side in a light, snug nursing pit, where they can have plenty of heat without becoming drawn. If potting on can be avoided, the fruiting pots or hills should be ready for their reception as soon as they have made a rough leaf and before the roots become cramped. Plants intended for trellis training do not require pinching, but are trained to sticks, thence over two-thirds of the wires, the which, top and bottom-heats being right, they speedily fill. The points are then taken out, lateral growths are laid in horizontally, and fruit being urgently required, they, in their turn, are stopped at the first or second leaf, when every succeeding break will show. The plants, however, being very young and only sparsely rooted, not more than one or two fruits should be allowed to swell at the outset.

Plants intended for the old-fashioned pit or frame should be shifted out of 3 inch into 5-inch pots as soon as they have made the first rough leaf, and when the roots touch the sides the points must be pinched to induce back breaks. Meantime a good body of fermenting material having been well worked and prepared, the beds must be made and the hills or long narrow ridges formed. If the plants are in advance of the bed, a few sods of turf, Grass side downwards, must be laid on the manure or leaves, and upon these large drain pipes, open at either end to let out fierce heat and prevent the compost and roots from burning. The greatest danger the very early frame cultivator has to contend with is rank steam from the beds and linings, and notwithstanding the fact that old hands managed without the aid of fire-heat, as I have seen Cucumbers cut from a manure frame on the 9th of March, the best way out of this difficulty is a flow and return pipe from a neighbouring boiler.

CHERRIES.

With a foot of snow and ice on the ground, and the external temperature hovering about 20°, the start with these impatient trees has been trying in the extreme. Still, those who would succeed must not forget that the most enchanting sight met with in English gardens—a house of Cherries in flower—will yet be theirs if through this storm they only exercise that grand virtue, patience. Dry fire-heat being highly objectionable, the usual reserve of fermenting leaves must be freely drawn upon, as a body placed upon the borders of floors throws up a continuous stream of mild vapour, which softens the atmosphere and keeps out frost in the severest weather. Not that frost even does any harm before the buds burst into flower: still no one wishes to find the mercury ranging below 32° on a sharp morning, neither should he expect to find it above 40°. Below rather than above, I think, would be preferable, and the slow, but sure, progress made should be due to light and gleams of sunshine. The temperature by day may range from 45° to 50° when black fog is doing its worst, and 5° to 10° higher when the atmosphere is clear—always, it must be borne in mind, with a liberal chink of air. If the

borders were well watered up to the time of starting, it is hardly likely they will yet be dry, especially where those containing old trees were heavily mulched in the autumn. Water, however, being such an important element in the culture of all stone fruits, there should exist no possibility of the soil becoming dry at any season of the year. Daily syringing, it is true, helps a little, but with fermenting leaves in the house the small quantity used simply moistens the surface, and for all other purposes becomes misleading. When the buds begin to show signs of opening, gentle fumigating to insure immunity from green and black fly during the time the trees are in flower will be necessary, for if these pests once gain a footing the chance of securing a crop will be very small indeed.

PLUMS.

Where these and Cherries are grown in pots, the two may be brought on together. Choice early dessert varieties are best adapted for forcing, and these should be thoroughly established or slightly pot-bound before they are taken in for forcing. Being subject to the same enemies, too much care cannot be devoted to the cleansing of trees and houses, and then even a constant watch must be kept for the advent of aphid. Although highly excitable, Plums positively refuse to be hurried; therefore, early fruit can only be secured by making an early start and giving the trees ample time through all the stages of their growth. When stoned, the fruit can be coaxed to full size in a moist temperate house, but no amount of confined heat will induce them to lay on colour and ripen. I once tried some very promising trees of Jefferson and Kirke's in a warminery, their fellows being left in a late orchard house. The latter coloured and ripened well; the former never changed in the hothouse, but finished off when placed in the open air. In this respect Plums in their mulish obstinacy often remind one of the Camellia which can be pushed to the colouring of its buds in the autumn, but casts its load under high pressure in the early spring. Other fruits no doubt often suffer under a much higher temperature than is good for them; in other words, a great deal of heat is wasted in the production of a second-rate article. Peaches, it is true, can be forced into ripeness in a Pine stove, but they are pale, rapid, and flavourless. Give them more time with plenty of air, and in every respect they become models of good culture. The old "saw" says, "it is the pace, not the miles travelled, that kills." The forcer against time says we must have fruit early. How, then, are we to get over the difficulty? Why, simply by treating all trees which will ripen their fruit in the open air in England as we now treat early forced Vines. With these we do not fritter away the whole of the summer in ripening up the wood, but push them on to thorough maturity; then give them a long and decided rest, and, knowing the exact number of weeks it will take to produce the next crop of fruit, we start early enough to allow plenty of time for the performance of each stage of their growth.

Late Plums.—After so much inclement weather it is hardly likely any of the winter work indoors will now remain in arrear. If it does, no time should be lost in getting this, generally the last, and the latest Cherry house put in order. February is now close upon us, and, judging from the prominent state of buds generally in the open air, a rapid move may shortly take place, when the liberal use of insecticides will be attended with danger. Although the fruit from these trees will not ripen until late in the autumn and fire-heat may not be needed, the fact that glass excludes the cleansing influence of the elements renders a thorough putting in order absolutely necessary. When this work is finished, the roots, if inside, will require a thorough soaking, and all the air

practicable must be admitted night and day. As solar heat increases and the buds become prominent and tempting to feathered friends, nets must be cast over the ventilators to prevent them from taking more than their share, but not until the blossoms begin to open will it be necessary to regulate the temperature. If the potting of furnished pyramids has been delayed by the weather, the trees must be allowed to remain laid in until it becomes milder. Then they may be lifted and placed in their fruiting pots, but, bearing in mind that much valuable time has been lost, they must not be expected to do much this year. Such being the case, unless a cold late house is at command, the best place for the summer will be found in the plunging ground out-of-doors.

GARDEN FLORA.

PLATE 580.

THE TREE PÆONY.

(WITH A COLOURED FIGURE OF PÆONIA MOUTAN REINE ELIZABETH.*)

A HUNDRED years have elapsed since the first living plant of the Tree Pæony was brought to this country from the gardens at Canton, and the honour of introducing it is due to Sir Joseph Banks. He had heard of its existence in Chinese gardens, and engaged a Mr. Duncan, who was attached to the East India Company's service, to obtain plants of it and send them home. Through Mr. Duncan's exertions the first live Moutan was received at Kew in 1787. For 1400 years the Tree Pæony is said to have been cultivated by the Chinese, who would have us believe that it originated from *Pæonia albiflora*, also a native of China. But such is not a fact, for it is proved beyond doubt that the Moutan is a true wild shrub, indigenous not to the southern parts of China, but to the northern provinces of Ho-Nan and Nan-Kin, where it inhabits mountainous regions and whence it was brought to Canton. For countless generations Chinese gardeners have occupied themselves in raising new varieties of Hoa-Ouang (the king of flowers), as they call this Pæony, and fifty years ago Anderson asserted that they possessed no fewer than 250 distinct

Poppy-flowered Tree Pæony (*Pæonia Moutan papaveracea*.)

sorts representing all the colours which Pæonies are capable of producing. They have crimson of every shade to nearly black, whites, yellows, purples, roses, and even blues. These are said to be all self-coloured, for, singularly enough, the Chinese reject variegated flowers, regarding them as unnatural. Some varieties they call *Pé-Leang-Kin* (a hundred ounces of gold), in allusion to their great value. In 1794 a second variety was introduced by a Mr. Greville; this was named *rosea*, the flowers being of a deep rose-pink colour, while those of Sir Joseph Bank's plant were blush-pink and double. In 1806 a third

* Drawn for THE GARDEN in the Hale Farm Nursery, Tottenham, in June last.

PEONIA MOUTAN VAR. REINE ELIZABETH

variety was introduced, and this, because its flowers were single, and still is considered to be the type or wild plant. It was named papaveracea, the Poppy-flowered Peony, on account of the capsule being like that of a Poppy by reason of the seed vessels being enclosed in a membranous disc. The accompanying woodcut well illustrates this variety, which is white with heavy crimson blotches at the bases of the petals. The above varieties, viz., Banksi, rosea, and papaveracea, are all that are described in Anderson's "Monograph of the Genus Paeonia," given in vol. vi. of the Horticultural Society's Transactions (1838), but in Loudon's "Arboretum Britannicum" (1854) a dozen are described, all bearing Latin names. There are, besides the three just named, Humel, double blush; variegata, white streaked with violet and purple; rosea semi-plena, rosea plena, Rawesi, single pale pink; carnea plena, double flesh coloured; albida plena, double white, flushed with mauve;

- LIST OF SELECT VARIETIES.
- | | |
|---|---|
| Argueil de Hong Kong, crimson purple | Madame Stuart Low, salmon-red |
| Athlete, deep rose pink | Marie Ruyter, rose-pink, large |
| Blanche de Noisette, white bluish tinted | Osiris, very dark crimson |
| Bijou de Chiusim, pure paper white | Oberon Maria, pale pink |
| Carolina, pale salmon | Prince Trombetsky, deep lilac or violet |
| Cobnet M de dm, deep violet-purple | Rezia, bright aurantia |
| Comte de Flaudre, rose-pink | Reine Elizabeth, deep crimson-pink; one of the best |
| Confusions, deep pink | Robert Fortune, bright crimson, semi-double |
| Farezza, pale lilac striped | Rossini, semi-double, bright rose |
| Fragrans maxima fl. pl. | Saint ring, deep blood red |
| Imperatrice Josephine, rich rose, splashed with red | Sauveur de Madame Knerr, blush-pink |
| Lambertine, blush pink and violet | Triomphe de Madines, violet and crimson, large |
| Lactea, one of the best whites | Triomphe de Vanterfanden, rich violet |
| Louise Moncharlet, flesh pink | Vandermaech, pale blush |
| Lord Macartney, cherry crimson | Van Houtter, carmine |
| Madame de Vetry, bright rose | Zenobia, purple-crimson |
| Madame Laffay, deep rose | |

POSITION AND CULTURE.—The selection of the best spot in the open garden for a Tree Peony is

tion, then the best thing to do is to screen it at once from the morning sun, so that the plant may thaw gradually. In some districts no protection is necessary, and this is the case principally in upland gardens, which are colder than those in the valleys, and, therefore, vegetation does not start so early. In old days when Tree Peonies were as much thought of as Cattleys are now, all manner of devices were resorted to in order to tide the plants safely over our treacherous springs, for it was found that scarcely any amount of cold during the dead of winter harmed them. In many parts of the country, indeed, they came unscathed through the terrible winter of 1837 and 1838. Some bygone Peony fanciers used to plant on the north side of hills, so as to retard growth, but such situations had a counteracting effect, inasmuch as the young wood did not ripen, through want of sufficient sunshine. As to position, it is generally admitted that Peonies look best when isolated on a lawn, not far away from a shrubbery or a group of some sort, but so situated that they appear to have some connection with one or the other, as the case may be. Being deciduous, a spot should be chosen for them where they would be backed up by Evergreens for the sake of the winter effect.

A Tree Peony in a Scotch garden, Kevoek Bank, Lasswade.

The Tree Peony may be forced into bloom in early spring with very little trouble, but in order to get good bloom the forcing must be gentle. The plants set aside for forcing should be strong and well rooted, and the shoots should be well ripened. They will, of course, be in pots and in cold frames. About the latter part of January or the beginning of February a few plants should be taken into a house slightly heated; for a week or so they will require no attention, as the buds will be dormant, but as soon as the latter begin to show signs of swelling care must be taken that the plants do not suffer from drought. At this stage they may be taken to a house where the mean temperature ranges from 50° to 55°, and in this atmosphere the buds will swell quickly and the shoots lengthen, until about the end of February or early in March they will be showing bloom. During this slight forcing period the plants should be syringed daily if the atmosphere feels dry, but when in bloom a dry atmosphere is best in order to preserve the flowering period as long as possible, which, in a cool conservatory, will extend over several weeks when well flowered. They make noble

vase ornaments for rooms; a fair-sized plant will carry from six to a dozen blooms and buds. All the sorts may be forced equally well, but those which have the brightest or the most delicate colours are the best. Such sorts as Reine Elizabeth, Madame de Vetry, Madame Laffay, Lactea, Louise Moncharlet, and Lord Macartney are particularly suitable for forcing.

The best soil for Tree Peonies is a deep loam enriched by manure. It is most important to plant at the outset well, for no plant resents root interference when once established so much as the Tree Peony, and that is why it is so difficult to transplant it without ill effects. After fixing on a spot for planting it out permanently, a hole should be dug quite 4 feet wide and a yard in depth, removing all the soil if not a good loam. Put a good layer of rubble at the bottom for drainage, and then, with a layer of turfy sods on the top of this, put in the soil; after a week's

a matter of more importance than any subsequent attention which it requires. It must have an open spot away from the shade or shelter of trees; but, if possible, it should be sheltered from north and east winds, which, as a rule, prevail in spring, about the time when the plant is pushing out its new growths. It should be the aim of the cultivator to retard the growth as much as he can, and if the locality is naturally warm, the Tree Peony will require particular attention, otherwise a sharp frost in April will destroy both growth and bloom. It is the practice in many places, and a very good one, to protect the plants by a movable glass light, or by fitting up around them a temporary framework on which is placed muslin, canvas, or other thin protecting material during the most critical time, that is, from the time when the young shoots begin to lengthen till all fear of frosts is over. If a plant is overtaken by frost, without protec-

tion, then the best thing to do is to screen it at once from the morning sun, so that the plant may thaw gradually. In some districts no protection is necessary, and this is the case principally in upland gardens, which are colder than those in the valleys, and, therefore, vegetation does not start so early. In old days when Tree Peonies were as much thought of as Cattleys are now, all manner of devices were resorted to in order to tide the plants safely over our treacherous springs, for it was found that scarcely any amount of cold during the dead of winter harmed them. In many parts of the country, indeed, they came unscathed through the terrible winter of 1837 and 1838. Some bygone Peony fanciers used to plant on the north side of hills, so as to retard growth, but such situations had a counteracting effect, inasmuch as the young wood did not ripen, through want of sufficient sunshine. As to position, it is generally admitted that Peonies look best when isolated on a lawn, not far away from a shrubbery or a group of some sort, but so situated that they appear to have some connection with one or the other, as the case may be. Being deciduous, a spot should be chosen for them where they would be backed up by Evergreens for the sake of the winter effect.

interval, so as to allow the latter to settle, plant your Peony. The best, and in fact, the only time for planting is autumn, during September or October. Nursery plants are always kept in pots, and at planting time the roots should be disentangled and spread out. Being of slow growth, Tree Peonies require no pruning, except removing dead shoots. The finest specimens in this country at the present time are from 6 feet to 8 feet high and as much in diameter, but these plants are very old, some of them having been planted thirty or forty years ago. Specimens such as these have been known to bear as many as 300 flowers in one season—a floral display such as one seldom witnesses. The accompanying illustration represents a large Tree Peony in a Scotch garden. Mr. Bashford, who sent us the photograph from which the engraving was made, writes concerning it as follows:—

In Midlothian there are some magnificent old-established specimens of Tree Peony. They seem to flourish in any fairly good soil—that usually found in well-kept gardens. In several localities the largest and handsomest trees grow on sloping banks of light and deep soil, well exposed to the sun, and protected from fierce winds. During the time they are in bloom their wealth of colour carries all before them. The illustration is that of a plant in the garden of Mr. W. M. Wardrop, of Kevoek Bank, Lasswade. The above plant had more than a hundred blooms out at one time, none less than 6 inches in diameter, of a lovely satiny flesh colour, beautifully relieved by foliage of exquisite harmony.

PROPAGATION.—The usual and best mode of increasing Tree Peonies is by grafting them on the fleshy roots of the herbaceous kinds, but they may be also raised from seed or multiplied by division of the root, by layers, by cuttings, and by budding. In grafting scions on roots, *P. albiflora* and hybrids from it are preferred, because they do not throw up suckers in the way in which the common *P. officinalis* and others do. The grafting should be done any time between August and the middle of March, but French propagators prefer to do it between the second week of July and the second week of August, in order that the union may take place before winter sets in. An expert propagator thus describes the operation: Select, he says, some good tubers of some herbaceous Peony, then slit each tuber from the crown downwards about 2 inches. Cut the scion in the shape of a wedge and insert it in the slit made in the tuber, taking care that the bark of both the tuber and scion fits exactly; then bind with bast and wax in the usual way. Put the grafted tubers in deep pots, cover with soil to the top of each tuber, and place the pots in a frame, which must be kept close and rather dry. If the operation is done in July or August, the scion will be united by September; by October the stock will have developed roots, so that in this way the plants are able to withstand the winter well in a cold frame. After they have made one season's growth under frame treatment they should be planted out and treated as established plants. This is the mode followed by the best growers in France, and is found to be the most satisfactory. Layering is another simple way of propagating Montans. If the previous year's shoots are tongued and pegged down firmly in autumn they will throw out roots the first year from each bud, and during the second year after layering may be safely removed from the stool. Propagation by budding and cuttings is also carried out, but it is found that plants raised from cuttings remain in a weak state for several years. Dividing the roots for increase of stock may be done any time during autumn, care being taken that each division carries a few fibrous roots. Seedling raising is not much practised in this country, because it

is seldom that seeds are thoroughly ripened, but in France where the climate is more suitable for seed-ripening, seedlings are raised with the view of obtaining new varieties. It is an interesting, though slow, process; the seeds take a year or eighteen months to germinate, and the seedlings flower when from five to seven years of age.

CULTURE OF EARLY VEGETABLES.

ASPARAGUS ROOTS FOR FORCING.—It is necessary, where a succession of forced Asparagus has to be kept up from the end of November till it can be obtained in the open ground, to provide a large number of plants for the purpose. It is, I think, generally admitted that Conover's Colossal has more vigour early in the season than the common variety, and where the principle is adopted of raising a special stock of plants for forcing without interfering with established beds, a variety that displays early vigour is valuable for that purpose. Where there is space under glass, it is an advantage to sow the seeds in boxes early in February, and bring them gently on in heat, pricking the young plants off either into single pots or other boxes when large enough, and planting out finally when hardened off early in May. It would not cost more to raise Asparagus plants in this way than it does the same number of bedding plants, and it would shorten their probationary period considerably. Another matter in connection with Asparagus culture may be usefully noted at this season, and that is, to place any spare frames and lights on one or more of the strongest beds, to encourage the crowns to start early, simply by utilising the sun's warmth in connection with the shelter afforded. This will fill up the blank which usually occurs between the last of the forced produce and the first from the open ground.

CAULIFLOWERS IN HEAT.—It is always a good plan to sow a few Cauliflower seeds now in heat, and if pricked singly into small pots and grown on in a light, warm house near the glass, hardened off and planted out in a warm, sheltered situation in April, they will not be much (if any) behind the plants raised in autumn, and in a general way they are more reliable, being less likely to bolt. The best forcing Cauliflower is Veitch's Forcing. It is not large, but it is very close and white, and turns in quickly. It forces very well in pots plunged in a bed of leaves in a low pit. Veitch's Autumn Giant Cauliflower is even more valuable early in August than it is later in autumn. Very often in a hot, dry time the other Cauliflowers are bolted and useless, but the Giant never runs; but to come in so early as the beginning of August the seeds should be sown now in heat, the young plants pricked off, and kept under glass till strong enough to go out in April.

SPRING LETTUCCES.—The long spell of cold weather will check, if it does not injure, open-air Lettuces, and those who have the means might with advantage sow a box of Early Paris Market Cabbage Lettuce and place the box in a temperature of 55° to 60°, and whilst the seeds are germinating, or at least as soon as they are up, a bed of leaves may be made up, using just enough stable manure to bind the leaves together. On this bed 4 inches or 5 inches of soil may be placed, and the Lettuces pricked out 4 inches apart when large enough. Any temporary arrangements as regards covering will suffice to bring them on, though good frames and lights are best.

EARLY POTATOES IN POTS.—These succeed very well in 10 inch or 12-inch pots, two sets in each pot, or larger pots may be used, increasing the number of sets. In planting the Potatoes space should be left for earthing up when the tops are 6 inches high. It is better to do the moulding up at two or more times, giving the fresh compost

in the shape of top-dressings, and, in that case, the earthing-up will begin before the plants have made much growth, and will be completed when they have attained the height named. The pots as soon as the Potato tops emerge from the soil should occupy a light position in a house or pit where the night temperature does not fall below 50°. The nearer the glass they are, provided contact is avoided, the stronger the growth will be and the better the crop. Uncut sets are best, but only the best central crown eye should be permitted to start and form a stem. The pots should be drained by placing some large crocks over the hole in the bottom, and 2 inches of rough siftings from the potting bench over the crock to form a dry base, as anything like stagnation will check the growth of the young Potatoes and cause them to be close and waxy.

CELERY FOR SOUP IN SPRING.—It is not everyone who has the means of forcing Celery for flavouring purposes after the blanched crop has either been used or has bolted or decayed, but if a few seeds of a good hardy red kind are sown about the middle of April, and the plants pricked out on a west border without any special manuring 8 inches apart, very useful Celery for flavouring purposes will be obtained that will last the greater part of the summer, or at least until plants from the earliest beds are available. Celery is a native plant, and the late-sown unblanched plants are hardy enough, but to make sure, a few dry Oak leaves may be scattered among them when severe frosts sets in.

EARLY GREEN LONG-POD BEANS.—I should think scarcely anyone now plants the Early Mazagan, the Early Long-pod being so much superior to it in quality, and besides it is a better cropper. The Early Long-pod may be planted rather thickly in boxes, and placed in heat till 2 inches high, and then hardened off to be planted out in rows when the weather is suitable, sheltering them at first with branches till the end of February or beginning of March. Long-pod Beans transplant even better than Peas, and those who like Beans especially appreciate an early crop. E. HOBDDAY.

NOTES ON TOMATOES.

SEVENTY-SIX so-called varieties of Tomatoes were grown in the Michigan college gardens last year. There were several reasons for undertaking this experiment. There has been very little attention given to Tomato culture in scientific or experimental establishments, although the importance of the crop is very great. The varieties of Tomatoes, too, are now so numerous, and their individual merits so evenly praised, that the inexperienced cultivator is confused. The Tomato rot is also becoming a serious difficulty, and methods of training and culture need to be discussed.

THREE METHODS OF TRAINING were employed this year, and another method last year. All the experimental Tomatoes were tied to one, two, or three stakes about 4 feet high. This method has many disadvantages. It requires much labour to tie the plants, a labour which must be repeated at short intervals throughout the growing season. The Tomatoes do not ripen evenly and early, and it requires extraordinary time and labour to pick them from the dense mass of stems and foliage. Last year we laid old boards lengthwise along the rows and close to the plants, supporting them upon pieces of scantling or blocks laid upon the ground, and placed straw upon the boards. This method kept the Tomatoes clean, but it certainly caused the lower ripe Tomatoes to rot prematurely. In our market patch this year we adopted two sorts of racks. The first was a separate rack for each plant. A stake was driven on either side of the plant, about 15 inches from it, and leaning so as to make an angle of about twenty degrees with the perpendicular. Upon these stakes three cross-slats were nailed, in the manner of a ladder. The plant was allowed to lie upon the racks. It was found necessary to tie it, however, and even then branches slipped off or broke themselves

over the slats. The second of these racks was continuous throughout the row. About every 6 feet or 8 feet a stout stake was driven on either side of the row and 15 inches from the plant, the stakes when firmly driven standing some over a foot high. A strip of old board was nailed near the tops of the posts along either side of the row. Then edgings were tacked across from one side to the other, four about each plant and a foot apart. The plant now found itself growing up between the horizontal edgings, and as it began to lop the rack held it above the ground. Upon this simple rack the Tomatoes needed no tying nor training, and they spread themselves freely to the sunlight. The circulation of the air under the racks was so free, that there was no unusual danger from rot. This is decidedly the best rack which we have tried. We noticed, also, that the fruit ripened more uniformly here than on the plants which were tied to stakes.

TOMATO ROT.—Green Tomatoes have rotted to an unusual extent this year. The rot first appears as a slight spotty discoloration about the apex of the Tomato, gradually extending and becoming darker until the whole top of the fruit sinks in. The disease attacks the fruits at any time after they are a third or quarter grown. It threatens to become a serious obstacle to Tomato growing. Tomato rot is, of course, of fungus origin. The microscope reveals abundance of bacteria and the mycelium of some higher fungus, as well as occasional isolated septate spores. As yet we know of no remedy. The first preventive which suggests itself is to plant varieties which are least liable to attack. Some are of opinion that the fruits on the most vigorous plants are most liable to rot. Such has not been our observation. We occasionally observe plants in no way distinguishable from others which are nearly exempt while all the contiguous plants are much affected. The per cent. of disease is ninety or above in Emery, Paragon, Rochester, Livingston's Acme, Market Champion, Golden Queen, Perfection, and Livingston's Favourite, while among the market varieties the per cent. is nothing or unimportant in Prize Belle, Advance, Mikado, Yellow Vietor, Red Valencia Cluster, Precursor, Fulton Market, Golden Trophy, Island Beauty, Boston Market, Golden Queen, Conqueror, Gen. Grant, Cardinal, Trophy, Criterion, Canada Vietor, The Cook's Favourite, Hundred Days, and Alpha. The affected varieties were scattered among others, causing them to appear as if especially liable to attack, but further observations must be made before definite conclusions can be arrived at. It is singular that the angular varieties, the Cherry and Pear-shaped varieties and those immediately derived from them have been almost exempt from attack. The disease ceased to do much damage late in the season. It appears probable that rotation in cropping will prevent the disease to some extent.

PRODUCTIVENESS.—An average plant of each variety was pulled up when the first picking was well matured and the plant and its fruit were separately weighed. While this method of determining productiveness does not give the absolute weight of produce of each plant—many of the fruits being but partially grown—it nevertheless gives an accurate relative knowledge of the productiveness of varieties. The most prolific variety—the one which shows the greatest ratio of fruit to weight of plant—is not always the most profitable, even when earliness and quality are not to be considered; that is, the plant itself must not be too large, else the cost of training it will be too great. Other things being equal, the dwarfest plant is usually the most profitable. I expect that the same variety will vary much in productiveness in different years and under different treatment. In fact the same variety from different sources varied widely this year. The best ratios occurred in Mikado, Trophy, Canada Vietor, Hundred Days, Precursor, Livingston's Beauty, and Large Red Smooth Round.

VARIETIES.—The earliest varieties were Advance, Precursor, Boston Market, Tom Thumb, Conqueror, and The Cook's Favourite. These all

began to ripen about August 6. The early season was so very dry, that none of the varieties produced fruit so early as they should have done. The seeds were all sown in a forcing house March 18, and transplanted, ten of a kind, to the open ground June 7 and 8. It is probable, however, that small differences in earliness are not to be relied upon in estimating varietal characters. Careful experiments upon this point, running through three or four years, conducted at the New York experiment station, show great variations in the comparative earliness of varieties. Although the list of varieties as reduced contains some forty sorts, all the desirable kinds for general cultivation are not more than six. From our experience, I should select the following, viz.: Boston Market, Conqueror, Red Valencia Cluster or Queen, Trophy, Livingston's Beauty, Paragon. If the rot should continue to attack the Livingston's Beauty and Paragon to the same extent as this year, they will need to be discarded. The Trophy is apt to grow too irregular.

In order to determine if all seedsmen send out the same Tomato under the same name, we grew Paragons from nineteen sources. Although all these plants bore fruits which had most of the essential features of the Paragon, it was nevertheless an easy task to select from the patch whole plants which might have been taken to represent several different varieties. This fact proves the unfixity of varieties and the necessity there is for exercising caution in sending out new ones.

L. H. BAILEY, JUNR.

Agricultural College, Michigan.

EARLY CARROTS.

In most establishments a constant supply of old Carrots is needed, more especially for flavouring soups; but if these are supplemented by unbroken supplies of very young or small roots fresh from the ground, much more satisfaction will be given. From the late autumn to the early summer months the variety of choice vegetables is somewhat limited, and it is during that time when an occasional dish of small, deliciously tender Carrots is most appreciated. A little extra trouble must be taken in their production, but the expense entailed is comparatively trifling. One or two frames and slight hotbeds are needed in the production of early spring crops, though these can be soon dispensed with, and the later supplies may be drawn from the open ground. As early in January as possible a quantity of leaves and stable manure should be mixed, and thrown together into a large heap, and turned once or twice at intervals of about a fortnight, or when found to be heating strongly, thus getting rid of noxious gases, generated principally by the stable manure. If more leaves than manure are used, there is less need for such careful preparation, but if stable manure preponderates, or is wholly used, the beds must not be too quickly made up. We form our beds about 3 feet high at the back, and somewhat lower in the front, and rather wider than the frames to be placed upon them. The shallowest frames are most suitable, and these after being set on the bed may be partially filled with the shortest of the heating material, or if there is any danger of the bed heating too strongly, rotten manure would be best for the purpose. On this about 6 inches of fine sandy soil should be placed, nothing being more suitable than that obtained by sifting over a heap of old potting soil. When completed, the soil should be very near the glass, and in most instances the seed may be sown at once, though some prefer to wait till the soil is warmed. The seed may either be sown broadcast and covered with a little fine soil, or shallow drills can be quickly formed with the aid of a short measuring-rod pressed into the soil, or firmly worked backwards and forwards. In any case the seed ought to be sown thinly, or much thinning out will be needed subsequently. The drills should be drawn about 4 inches apart, and the Carrots may alternate with Radishes. The latter growing much the most quickly can be drawn long before the Carrots will require all the space. Radishes may also be grown with those sown broadcast. Although the early French Horn is the quickest grown Carrot, I yet prefer the Nantes Horn; this,

being available when nearly the size of Radishes, is usually of a better colour than the French variety, and yields a longer succession. In fact, we neither grow nor recommend any other variety for frames, warm borders, or late sowings. Wood's Frame is yet the most profitable early Radish, and by way of variety we also grow the Forcing Red and White Turnip and French Breakfast. After the seed is sown the frame is covered with litter for a few days or till the Radishes are coming through the soil, when they are covered at night only, and when the weather permits a little air is admitted during the warmest part of the day. This is necessary to keep the Radishes sturdy and thereby insure early bulbing. The Carrots are much later in germinating, and will not be materially checked in growth by the air given. In both cases the more thinly the seedlings are left in the rows the more quickly do they bulb. We leave each about 2 inches apart, and thin out according as they are fit for use, the last of the Carrots being usually large and handsome. While the Carrots are growing strongly plenty of air should be given in the daytime, the lights being drawn off on warm days and also when warm showers are falling. The Carrots require occasional gentle waterings with tepid water, and after pulling has commenced the frames may be wholly removed and the sides of the beds supported with stakes and boards. One two-light or three-light frame is sufficient to meet the requirements of most moderate-sized establishments, but where a town house has to be kept well supplied, a second and perhaps a third frame has of necessity to be sown at monthly intervals. In this case very little bottom heat is needed, or it may be dispensed with altogether. In very many gardens frames cannot be spared for vegetable forcing, but in spite of this it is yet possible to have a good supply of

EARLY CARROTS WITHOUT GLASS.—Some time in February or early in March, a good-sized heap of heating material, or, say, a mixture of fresh stable manure and leaves, with an equal quantity of partially spent linings or early hotbed material, may be collected. If a small quantity of hotbed material only is available, then a small bed should be formed, this being from 2 feet to 3 feet high at the back, with a gentle slope to the front. On this a rough board frame may be placed, and kept in position by tall upright stakes driven into the hotbed, and these stakes also serve for supporting any protecting material that may be used in the form of mats, and perhaps some fish netting to preserve the Radish seed from birds. From 6 inches to 9 inches of good light sandy soil should be levelled over the surface of the bed, and the seed can then be sown as advised for the frames. The young plants may be considerably forwarded by protecting them from cold winds and late frosts, but even without any protection and with very little attention, they will be considerably ahead and much superior to any raised on sunny borders. It is really surprising what a number of dishes a bed about 6 feet by 4 feet will produce, giving more pleasure perhaps than any other vegetable-growing corner in the garden. It is from such beds as these that some of the prettiest dishes are drawn for the July and early August shows. If fewer Radishes are grown, these outside beds are also available for raising early Lettuce and Celery plants, and perhaps a few Brussels Sprouts and Autumn Giant Cauliflower. In such cases the seed must be sown thinly, thinning out be well attended to, and the plants be pricked out on a warm border before they smother the Carrots among which they are raised. Failing a hotbed of any kind, one of the warmest corners in the garden may well be devoted to early Carrots. This should be dug early in the winter, and as soon as workable, or, say, any time during March, a liberal dressing of leaf soil, common peat, or old potting soil be forked in and well mixed with the garden soil. A light sandy soil invariably produces the earliest and cleanest Carrots, and if a corner is specially prepared, this may annually be given up to them. In large gardens a good-sized border ought to be devoted to early Carrots, the seed being sown in shallow drills 9 inches apart as early in March as the state of the ground permits. From such a border we last season commenced drawing in close succession to a second frame, and, incredible as it may appear, we have continued to pull two or three times a week

ever since, plenty being still available. Only Nantes Horn was sown, and this valuable sort, if very lightly thinned at the outset, seems capable of renewing growth according as the larger roots are removed. The cook prefers it to any other. It is also the best for sowing in June and July in the open or in frames for the purpose of affording a winter supply of young tender roots, these being protected from severe frosts and drawn as required.

THE GENERAL CARROT CROP is frequently too large as regards size of roots for the kitchen, and is better fitted for the stables. On some soils it is a difficult matter to prevent coarseness, and we found it so for a time. Latterly we have not sown so early as heretofore, and have not thinned out so freely. We grow two or three where one was obtained before, and these are smaller and of a better colour and quality accordingly. Neither a heavy nor a very rich soil is suitable for the production of good Carrots. If it has been well manured for a previous crop, this will usually suffice for the Carrots also. Heavy land will be greatly improved by being roughly dug early in the winter, and again forked over or turned early in March, in which month the drying winds and sunshine will thoroughly bake it, the April showers completing the disintegration. On light soils we would sow the seed late in March or early in April, but on strong lands the middle, or even the end, of April will be found quite early enough for sowing. If the ground cannot be got into good working condition to the depth of at least 6 inches, it is frequently advisable to wait till it can, as clean, straight roots ought not to be expected from ground broken fine on the surface only. The drills to be drawn 12 inches apart, and after the seed is sown thinly it should be covered with the soil if this is in a fine condition, otherwise it is most advisable to cover it with fine sifted soil, which can usually be obtained from most frame grounds or back yards. Where the Carrot maggot is troublesome, a liberal sprinkling of wood ashes should be sown with the seed, and, failing this, soot may be substituted, plenty of this being also stirred into the surface in showery weather while yet the Carrots are small. If sand is well mixed with the seed it can be sown thinly, and the process of thinning out much simplified. The thinning should be done before the plants spoil each other, the Intermediate, Long Surrey, and Altrincham being finally left about 6 inches apart, and the Nantes Horn still more thickly, the rows of this variety being not more than 10 inches apart. All may be drawn in October or early in November, have their tops cut to near the roots, and be stored in a cool shed, biggest end outwards, and among either sand or dry, light soil. Veitch's Matchless, or the New Intermediate, is a decided improvement on James's Intermediate, more especially as regards the colour, and this novelty ought to quite supersede the older form. Both Altrincham and Long Surrey are good keepers, and valuable accordingly. It is my belief that Nantes Horn can be had as late as any, and I strongly recommend it for late as well as early crops.

W. I.

KITCHEN GARDEN NOTES.

TRENCHING.—As showing the severity of the weather as far south as Northants, we have this week, in order to find employment for our regular staff of men, had to shovel the snow off the ground in order that we might continue the trenching that was started before the storm commenced; and fortunately, owing to there having been but little frost before the snow fell, the ground was found to be soft and easily worked. Our plan is, as each trench is completed, to throw the snow from the untrenched ground over that which is finished, but only clearing so far as the next trench is to extend. Thus, however hard the frost may be, the snow prevents it from taking hold of the soil, and by taking the precaution to cover up the open trench at night with mats, we are able to keep on with the work continuously. The plot now being trenched is intended for a main crop of Peas, and we are therefore breaking it as deeply as the character of the subsoil will

allow. The latter consists of a sandy gravel; hence we do not bring this to the top, but break it up, and over it place a layer of long litter, on to which the top spit, or surface soil, is turned, and over this again is placed a layer of shorter manure; then comes the topmost layer of soil, which has reversed positions with that laid immediately over the long litter, and the process is complete. We invariably have a longer or shorter spell of dry, hot weather, but Peas planted in ground thus treated, and surface-mulched when they get into flower, rarely fail to give us satisfactory returns, and we have never occasion to resort to artificial watering; nor, in fact, do we water any other kitchen garden crop, except Celery and sometimes Cauliflower, and occasionally, too, a tit-bit of a crop that we require for a special purpose, and then we give manure water.

BRUSSELS SPROUTS.—This is the winter vegetable *par excellence* in all seasons, but during the present severity peculiarly so. It is about the hardiest of all the Cabbage tribe; in fact, with the exception of Curled Borecole or Kale, it is the only green vegetable that we can at present supply in quantity. Perhaps no vegetable crop better repays the labour of high cultivation than this does, and none is a greater failure if painstaking culture be not taken with it. In deep, rather stiff and rich soil, the plants if put out any time during March will attain a length of from 3 feet to 4 feet, thus giving abundant space for the free production of Sprouts. Short-stemmed Brussels Sprouts I look upon as capable of producing at most but half a crop, and on this account I would neither grow nor advise others to grow short-stemmed kinds. Why have but a gallon of Sprouts from a stem when from the same ground and the same amount of labour it is possible to have a peck? By constant selection of the longest-stemmed, combined with the hardiest buttons or sprouts for seeding purposes, we are in possession of a strain, that even in but moderately good ground attains a yard in height with sprouts from the ground-line to the top. We shall sow in a day or two, in boxes filled with light loam, which will be placed in a cool Peach house to germinate. The seedlings will be kept well up to the light, and as plenty of air will be given to the Peach trees, this will ensure sturdy growth. As soon as they can be handled and before the roots get entangled together they will be pricked out, either in a cold frame or in shallow boxes filled with leaf soil and loam; about the end of March they will be ready for planting in the open ground in deep drills, which at first form a shelter from cutting winds, and as the plants grow and the soil is levelled down there is a good foundation of soil to keep them firm till such time as the usual ridging up is needed. I ought to add that the plants are a yard apart in the row, and that the rows are 4 feet asunder. Small hard sprouts are generally preferred to large ones, but as regards quality or flavour I have not yet discerned any difference between the two. As appearances, however, always count for something, the smallest we reserve for the dining-room and the largest for the servants' hall, in which they are just as highly appreciated. Some few years since we used to sow the seed thinly in drills where they were intended to remain, and had excellent success, but slugs and grubs at last got too many for us, and therefore the practice was given up in favour of the plan just named. For the benefit of anyone who may be desirous of trying this method, I may say that the drills were drawn rather deeply, the distance apart the same as above stated, and then 2 inches of sifted soil—loam, leaf soil, and a little soot—were put along the entire length of the drills; the seed was then sown thinly and covered with more of the same fine soil. Thinning out was not done till we felt pretty sure that slugs would not injure them, and when finally thinned, more fine soil was placed round the stems of any that seemed weakly or that bent out of the perpendicular, and eventually the drills were filled into the ground-line, and till this was done our anxiety as to the depredation of slugs and grubs did not end.

CAULIFLOWERS.—Having some fear that this harsh winter will prove fatal to a large portion of the autumn-sown plants, we have made a sowing in pans and placed them in warmth to be pricked out in frames as soon as they are 2 inches high. Broccoli are being hardly hit, and the more tender sorts will be killed outright; therefore, early Cauliflowers will be doubly valuable. If frame room can be spared to admit of their being pricked out 4 inches apart, so that they can be transferred with good balls of earth to a warm border, the probability is that they will turn in quite as early as autumn-sown plants. The earliest varieties are, Extra Early Forcing, First Crop, and Snowball, and as a succession to these varieties there are none better than Early London and Dwarf Erfurt. The first named varieties are so small and dwarf, that they need not be planted more than a foot apart each way; but the last named kinds require double that space.

SEAKALE is also likely to be in great demand; the suddenness of the storm found us unprepared with roots to succeed those already in forcing quarters, but, thanks to the snow for keeping the frost out of the ground, we have managed to dig up a sufficiency for present requirements. The warmth and darkness of a Mushroom house make it the best of all places in which to force Seakale; but in the absence of such a place, plant the roots thickly together in large pots, cover them over with Seakale pots, and place them in warm corners in the houses. If a sack or mat be laid over the pots to exclude light, the Kale will be as well blanched as that which is grown in the darkest room. We reserve the small clean roots of all that have been forced for making fresh plantations at the end of the forcing season, and the roots meanwhile are heeled in under the shelter of a wall.

SPINACH.—Our winter plot of this is a complete failure. The plants grew away most satisfactorily, and we had gathered some half-dozen dishes when they began to die off most mysteriously; a sort of canker attacked the roots, and on examination with a microscope there were to be seen myriads of insects, so small as to be undiscernible without the use of a powerful magnifying lens. A good dressing of soot and fresh slaked lime was given, but all to no purpose, as nearly every plant dwindled away. We hear from several quarters that this crop is a failure; therefore our experience is not singular. Precautionary measures will be taken another season to ward off the disease, by applying a free dressing of soot, fresh lime, or a smaller proportion of gas-lime when preparing the ground for the crop. We shall make a sowing of the round-seeded variety on the first favourable opportunity, our usual position for Spinach throughout the summer being in single lines between rows of Peas.

FLOWER GARDEN.

WHITE DAFFODIL TRIAL.

MR. BURBIDGE still holds a brief for Chiswick, but rather ignores my argument, which still seems to me only reasonable, that the proposers of Chiswick should demonstrate its suitability. Let me repeat that what is required is not a place where white Daffodils will live, but one where they will flourish so happily as to show all their delicate shades of difference. It will much surprise me if our friend Mr. Walker decides that they are likely to display their characters to this perfection at Chiswick or elsewhere in the near neighbourhood of London. I was not aware that the trial was to be for the sake of "affording satisfaction to the Narcissus-loving public generally." Surely to that public one white Daffodil is the same as another, only rather more so! The trial, I took it, was for the satisfaction of a comparatively small number of the more attentive students of these plants. Mr. Burbidge misunderstands me in his remarks about the necessity of self-denial. If, after imparting to friends, I have only some half-dozen bulbs of a little known variety left, I do not think

I am indulging myself, but furthering knowledge, if I keep them where they grow so well until I have looked at them long enough and carefully enough, at all events, until I hear of some place where they will do as well or better. Mr. Burbidge knows that we can form a judgment from six plants where we cannot from one or two. I had not dreamed that there were so many kinds of white Daffodil in existence as Mr. Burbidge's, which require twenty-two years for their arrangement. And, he says, Mr. Hartland has still more. Let us hope we may have descriptions and figures of them from time to time. Two springs, I think, will about suffice for sorting mine, although I had fancied Mr. Hartland had only one, a very pretty white minor, not possessed by me.—G. H. ENGLEHEART.

The Royal Horticultural Society's garden at Chiswick has for more than half a century been a place for experimental trials of garden plants, and there much useful work has been accomplished. As regards white Daffodils, the conditions requisite for their successful culture can certainly be found at Chiswick, but a sub-committee, including Miss White and Mr. Engleheart, should be appointed to select a spot, with power to instruct as to the depth of Banstead loam to be used and other details of culture that may appear to be necessary, and one or more of the committee should attend to the planting. The quantity of bulbs will not be great; a small space will therefore suffice, and if thought desirable a movable frame might be used, or boards nailed to posts close to the ground, so that the soil might be raised above the general level, if considered an advantage. Instead of three bulbs of a sort I would suggest that one good bulb of each kind should be sent, as many amateurs, &c., might not be able conveniently to spare three bulbs, but could send one bulb each of many sorts. From what Mr. Burbidge and others write, if Ireland puts her forces in the field, England will be nowhere numerically; still we must do our best not to be too far behind. Mr. Wolley Dod will, no doubt, send his albino pseudo-Narcissus. I may be able to contribute in this line also; to these I will add the white Daffodils raised by Mr. Edward Leeds and Mr. Backhouse, and the four sorts which I suppose to be those recorded by Haworth, with any others I may possess. If the proposed trial does not fall through, I should suggest to the planting committee to provide for annual additions, and if we find white Daffodils a success, we may follow up with two-coloured and self yellows, incomparabilis, &c. Mr. Buxton, who first collected the white Daffodil of the Val d'Arras, and who has been many times over the ground, could, no doubt, give valuable information as to whether it grows in hollows, on the side of the hill, or amongst brushwood, while Mr. Maw, who followed Mr. Buxton, and, no doubt, took a more scientific view of the plant and its surroundings, might add a great deal of valuable information, not only as regards the requirements of this Narcissus, but others he has found at various times and studied them in their native habitat.—P. BARR.

Early history of Chrysanthemums.—One of the earliest papers on the Chinese Chrysanthemum of which I have any record is that in Paxton's "Magazine of Botany," vol. 1, p. 187 (1834). The history there reprinted is from a paper read in June, 1828, before the Vale of Evesham Horticultural Society by the president, Mr. E. Rudge, and, apart from the early history as given below, there are cultural details of the time, which are now obsolete. To a digest of Mr. Rudge's paper a list of fifty-three varieties is appended. Haworth's classification of the varieties then known appears in another place in THE GARDEN of Jan. 17, 1866, in 1753, first published this plant as a species, with two of its varieties, under the name of *Chrysanthemum indicum*, in his first edition of the "Species Plantarum"; the same plant, under the name of *Matricaria*, having been given by Kämpfer, in 1712, in his account of the plants of Japan, where it is cultivated by the natives in their gardens, and he describes eight double varieties of the genus of various colours. It is also mentioned by Breynius, Plukenet, Klode, and Petiver. Thunberg mentions in his "Flora Japonica," published in 1784 that it grows spontaneously near Nagasaki and other places in Japan; and Loureiro, in his "Flora of Cochinchina," mentions it as one of the plants of that country. Rumphius, in his very elaborate work on the "Plants of Aumoyna," published in 1750, is more particular

in his information respecting this plant than any preceding author. The Chinese, by whom it is held in high estimation, pay much attention to its culture; they keep it in pots and jars, placing it before the windows of their apartments, and decorate their tables with it at their entertainments; on which occasions he who produces the largest flower is considered as conferring the greatest honour on his guests. The varieties of this plant were introduced to Britain from France in 1790, having been brought from China to Marseilles in 1789. Before 1808, eight new varieties were introduced from China by Sir Abraham Hume and Mr. Evans. Between the years 1810 and 1823 seventeen new varieties were added to the list.—F. W. GERRIDGE.

IXIAS AND OTHER CAPE BULBS.

IXIAS in early summer are welcome, even though there is at that season no lack of beautiful flowers. They are so graceful, bright, and varied, that they are different from everything else, and anyone who has a spare frame could not put it to a better use than fitting it in autumn with Ixias or other Cape bulbs, such as those of Sparaxis and Babianas. Speaking generally, Ixias require frame culture, but there are many localities in the southern counties where even this protection is unnecessary. We have seen very fine crops of Ixia flowers at the foot of a warm south wall in a Sussex garden, the only attention bestowed on them being a few Spruce boughs placed over their tender growths in spring, when biting east winds prevailed. Both unprotected and in frames, the Ixias and their allies must have a light sandy soil in which to grow, and it must be well

Flowers of Ixias; colours various.

drained, so as not to retain moisture to make it cold in winter. They must also have an open spot where they can catch every ray of the winter's sun, for it is in winter and early spring when these Cape bulbs are in their most active growth, and that is why they are rarely seen so finely grown as they ought to be. A mistake too often made is planting them too late, as is also frequently done in the case of Dutch bulbs. But Dutch bulbs may be planted after Christmas with good results, though a wise grower knows that very much better results may be expected if they are planted during October or November. In the case of Ixias, Sparaxis, Babianas, they must be planted in September, because, naturally, they have then ended their resting period, and have begun to start again into active growth. The bulbs of these plants may be bought in August and September, and as soon as received they should be planted either in frames, warm borders, or potted, for with a little attention they can be grown to perfection in pots, and they are then valuable for conservatory decoration, as they can be forced into bloom as early as March. Not too much heat and all the light possible are what forced Ixias require. In open borders they need great care in spring when their tender foliage is above ground, or cold winds will soon injure it. Many varieties of Ixias may now be bought, but these have all sprung from comparatively few

species, and some of the original species introduced 150 years ago are still as beautiful as the hybrids. Among these crateroides, columellaris, fucata, flexuosa, and the singular sea-green viridiflora are notable instances. A dozen of the best sorts of Ixia would include the following: Aurantiaca major, yellow; Aurora, bright pink; Diana, white and purple; Garibaldi, rose and purple; Golden Drop, yellow; Hector, rose, black centre; Vulcan, crimson; Wonder, rose-pink; Ida, orange and crimson; crateroides, cherry-rose; Brutus, maroon-crimson; columellaris, bright red. This selection would represent all the colours to be found among the Ixias, and when in bloom would produce quite a glow of bright colours, lasting in perfection for several weeks, and invaluable for embellishing vases in a cut state. W. G.

Double Peach-leaved Campanula.—I do not know whether this hardy flower will bear forcing or not, but it certainly is much improved by being grown under glass during the flowering period. In the open air the blooms are apt to get soiled, and sometimes quite ruined by inclement weather. They are so double, that they soon suffer from excess of atmospheric humidity, but in a cool house they come as pure and well formed as those of the double white Camellia. When this Campanula is flowered in pots, the plants should be liberally grown in the open ground during the summer, and good sized clumps of it are more satisfactory than small plants. In some soils there seems to be a difficulty in keeping this Campanula in a robust condition. It is apt to dwindle and ultimately die out. This will happen in light, porous soils, the plants appearing not to be able to recover after having bloomed freely. There is evidently an element of tenderness in this Peach-leaved Campanula which only liberal culture can drive out; consequently, when the plants seem to have come into a more or less feeble condition they should get a top-dressing of rotten manure. Where this does not effect the desired change, replant in two or three spadefuls of good loam. This will soon work a great change in the condition of the plants.—J. C. B.

Christmas Roses in 1887.—The long expected hey-day of the Christmas Roses has come, and for once, I am sorry to say, they do not come up to our expectation, or quite do away with the "winter of our discontent." I do not remember to have seen all three varieties of the niger section, of which alone I write, so unsatisfactory. Niger maximus commenced to flower in October, as usual, but the blooms were few, misshapen, and unattractive all through the season. The ordinary *n. niger* is almost a blank as regards blooms, and what there are appear unable to expand. The gem of the family, *n. n. angustifolius*, has a sufficiency of flowers, and they are fair in size and purity; but the stems are so short that the plant is ineffective, and quite out of character, and the blooms greatly lessened in value for cutting, as they are so difficult to arrange. The only form of Christmas Rose which approaches tolerably the excellence of other years is Mr. Poe's superlative variety of maximus. What a noble presence it has! How it lifts up on high its broadly expanded saucer-shaped bloom, without trace of the rusty pink that disfigures the type! And how bravely does its broad disc of exquisite green challenge comparison with the lordly Eucharis itself! I have not yet seen a flower this season on some other varieties of the niger section, such as Madame Foucard and some choice strains from Germany, but I can see enough to enable me to judge that they cannot come up to the mark. As Hellebores succeed very well here, and as they had not been lifted or had had any change of treatment, I can only account for their comparative failure by the drought from which we suffered in this district last summer. The caulescent section of Hellebores is late in starting into growth. I am not sorry for that, as there is more chance of their escaping severe frost. It is possible that other persons' experience of Christmas Roses this season is more happy than mine. But I fancy it is not so in the case of any who

suffered equally with me from drought last summer. — FREDERICK TYMONS, *Cloghran, Co. Dublin.*

EARLY FLOWERING AND HARDY PLANTS.

THE LACED POLYANTHUS is one of the earliest of old-fashioned flowers to show growth above ground, and therefore the soil in the pots must be kept moderately moist, even in January. It also likes plenty of air, and does not thrive well with the lights of the frame in which it is grown kept too close. Except during cold east winds, I remove the lights altogether; this keeps the flower-stems stiff and erect. The leaves, too, are also thus kept brittle and short-stemmed. Greenfly is very troublesome sometimes, and if it appears it is best at once to fumigate. I cannot, in our dry, exposed garden, do much with these Polyanthus out of doors; whereas in gardens of a different character they do well. Plants in the open air are apt to be thrown out of the ground by frosts; it is well whenever a thaw comes to see that the stems are not exposed; if they are, place some dry loam around them up to the leaves, or press them into the ground with the fingers. In mild weather they make considerable growth even in January.

THE AURICULA does not show much signs of growth before February; indeed, it will not start while it continues to freeze as it does at present. Those who grow their plants in frames should place a mat over them at night whenever sharp frost is likely to occur. We have had our plants this year frozen through, root and top, and have some hope that the woolly aphid will not stand the low temperature to which it has been exposed. In the early months of the year we place a set of plants in a heated house, and others are left out in a frame behind a north wall for late flowering. Auricula seeds may be sown about the end of January, or at least not later than the first days of February. A good compost for them is equal parts loam and leaf-mould, with a little white sand. Sow in 5-inch pots or small pans, of course well drained. Let the surface be quite level, and cover very lightly with finely-sifted soil. Place the pans under hand-lights or in frames, and trust to the seeds vegetating slowly without any artificial heat. We have raised thousands of seedlings in that way, and also by placing the pots in a house where only sufficient heat was applied to keep out frost. Nothing is gained by putting them in a heated house, and a hotbed is sometimes more of a hindrance than a help, as a strong bottom heat will oft-times destroy the seeds. Alpine Auriculas in the rock garden must not be interfered with during frost, but when the frost is gone, if time can be spared, remove all dead leaves, and treat them as has just been advised for outdoor Polyanthus.

CARNATIONS AND PICOTEES.—We are just mixing our compost for potting these. I have found them to succeed best when this is done two or even three months before it is used, as by that time the manure will have become more perfectly incorporated with the soil. I prefer keeping the latter out of doors to housing it in a dry potting shed. The plants are now in cold frames, and we do not trouble to cover them with mats, however severe the frost may be. It is a mistake to allow the soil in the pots to become too dry even at mid-winter, but it is a graver error to water when the weather is frosty. We pull the lights quite off the frames, unless we have rain or snow or sharp east winds prevail. The plants do not suffer from a low temperature, but frosty winds certainly do harm; the lights may be tilted a little at the side opposite that from which the wind is blowing. Outdoor plants look well; a foot in depth of snow has thawed over them and has made the leaves clean and bright. I wish our plants had been covered with snow during the prevalence of cold east winds in February last year; hundreds of tender plants were then destroyed. So far, this winter has been exactly suitable for seedlings and named hardy varieties out of doors, at least where they have been well covered with snow, which is by far their best protection.

PINKS, when in bloom, are very lovely, and though not so popular as Carnations and Picotees, they are more hardy, easier to propagate, and, all things considered, are to be preferred by those who dislike garden frames, or perhaps cannot afford them. Pinks do not, as a rule, suffer much in winter, but they are sometimes injured by east winds. Branches of common Braeken or of Spruce Fir stuck amongst them shelter them greatly from north and east winds. Foreign Pinks, such as Lord Lyons and the pure white varieties, of which Lady Blanche is the best, will succeed out of doors as well as the laced section, and make excellent border plants. We have single plants of them in borders as much as 3 feet in diameter. They have been allowed to grow four or five years in good soil. It would take some time to count the flowers which such clumps produce. They were turned out in borders after they had been forced. Plants intended for forcing are plunged in frames, from which a few are placed in forcing houses at intervals. They should be placed close to the glass, and the temperature ought not to be very high to begin with.

RANUNCULUSES.—These should be planted out next month; but I find from experience that they are apt to degenerate unless the ground for them is well prepared. It is best to do this in autumn before it has become too wet. By preparation is meant trenching it up about 18 inches deep, or two spits, and mixing with it some decayed manure. Good medium clayey loam does well for a subsoil, if anyone should be so enthusiastic as to obtain old turf with which to form the beds. I always obtain some dry refuse potting soil, siftings from the Orchid houses or the potting bench, and place 3 inches of it over the bed. In this the tubers are planted 2 inches deep, and it forms an excellent medium for them, even if the soil underneath is quite wet. Tubers of the Scotch type do not produce very vigorous plants, and need not be planted more than 3 inches apart. French tubers are much more vigorous, and between each of these 4 inches may be allowed, and the rows may be the same distance asunder.

TULIPS show no signs as yet of making growth above ground, owing to the continued cold weather since they were planted. For many years our Tulips have taken their chance out of doors without any protection whatever. The system practised in the north of placing bent hoops over the beds and covering them over with mats may be necessary to protect the more tender varieties both from wet and frost; but, so far during seven or eight years, though unprotected, we have not lost a bulb. A layer of straw or Fern litter placed over the beds is a good protector. It ought to be removed when the plants have grown an inch or so out of the ground. Tulips look rather yellow when the covering is removed, but they speedily assume their usual green appearance. The raising of seedlings is a most interesting occupation. No flowers are easier to fertilise than those of Tulips, and there is no difficulty in obtaining plenty of good seeds. The latter, if sown in April, sometimes produce good plants the same season. An old grower who had a quantity of good seeds saved from one variety sowed some in October, and no plants was the result. A few from the January sowing came up. Better success attended the February sowing, and April-sown seeds produced bulbs weighing 4 grains, while the heaviest bulbs from the February sowing weighed but 2 grains. As a rule, all the seedlings produce self-coloured flowers, though the seeds be saved from the best flamed or feathered flowers. They break into flame or feather subsequently at uncertain intervals. J. DOUGLAS.

Christmas Roses.—I am glad that Mr. Wilks can amplify my notice of the N. Italian Hellebore. Clearly we both saw the same kind. I can well remember that the plants in question were tall and had very large leaves of a fine deep green. As to the season it will probably help Mr. Archer-Hind to know that most of the flowers appeared to be past, and that almost all spring flowers were unusually late in Italy last year, owing to the exceptionally cold winter.—G. H. ENGLEHEART.

FERNS.

W. H. GOWER.

HARE'S-FOOT FERNS.

AN interesting and beautiful family of Ferns are the Davallias, or Hare's-foot Ferns, as they are popularly called, all of which are natives of the eastern hemisphere. The species of Ferns belonging to *Humata* and *Leneostegia* are frequently included in the genus *Davallia*, but these possess good and distinct generic differences and ought to be kept separate. The Hare's-foot Ferns form grand subjects for the decoration of both stove and greenhouse, i.e., when grown into good sized specimens, while not a few of them, owing to the persistent character of their fronds, are admirably adapted for backing to button-hole bouquets and for grouping with bunches of flowers in vases. *Davallias* have long creeping rhizomes, more or less densely clothed with chaffy scales and hairs; these rhizomes or root-stalks vary considerably both in size and colour. In the European species (*D. canariensis*), the typical plant, the scaly creeping stem has a striking resemblance to a hare's foot; hence its name. The different species belonging to this genus are all surface-rooting plants, and their stems creep over the soil in which they are placed or rockwork in quite a picturesque manner when allowed to extend uncontrolled; they also form fine masses in baskets. As to kinds, the following are some of the best:—

D. CANARIENSIS.—This, the typical species, is the only European representative of the genus. It is said to be common in the south of Spain, where it is found growing on tree stems and rocks near the seashore. It is also found in Madeira and Tenerife, and in the neighbourhood of Gibraltar. The root-stock or rhizome is very stout, clothed with large rusty-brown hairs, from which spring its broadly triangular fronds. These latter often measure some 18 inches or 2 feet in height and about a foot in breadth: they are many times divided into numerous narrow segments of a deep green hue; when fertile the spores form a conspicuous feature, being pale yellow. This species succeeds well either in stove or greenhouse.

D. FENICULACEA is a Fiji Island Fern, of a bold, yet refined appearance. The fronds are some 2 feet long, lanceolate in outline, and gracefully arched; they are four times divided, the segments being narrow and forked, leathery in texture, and very deep green in colour.

D. BULLATA.—This is known as the Squirrel's-foot Fern, from the rhizomes being slender and thickly covered with chestnut-brown scales and hairs. The fronds are from 1 foot to 18 inches high and bright green. The species is deciduous, losing the whole of its fronds in winter; it must not, therefore, be depended upon for decorative purposes at that season, but during summer it will thrive in a greenhouse. It comes from Java and Japan.

D. DIVARICATA.—This is a bold and handsome stove plant, producing from its stout, rusty-red root-stalks large arching fronds, some 3 feet or 4 feet long. They are broadly triangular in outline and three times divided, the segments being large, coriaceous in texture, and deep green. It comes from Northern India and various islands in the Malay Archipelago.

D. DISSECTA.—This is a Javanese plant. It has a stout root stock, densely clothed with reddish brown scales. The fronds are somewhat triangular in outline, four times divided into oblong, cuneate segments, which are stout in texture and bright green.

D. PLUMOSA.—This plant, which is abundant in the Fiji Islands, is one of the most elegant Ferns yet introduced. The root-stocks are creeping, and the fronds, which are between 2 feet and 3 feet in height, are broadly triangular in outline and some four times divided, the ultimate segments being small, linear, and bifid. The fronds are firm in texture and deep bright green. In the variety *plumosa* the fronds are

less triangular and the segments are set more closely together, giving the frond the appearance of a huge plume.

D. PENTAPHYLLO.—This is a dwarfier plant than the preceding. It bears fronds about a foot long, and they are usually divided into two or three pairs of side pinnae and a terminal one; the pinnae are from 3 inches to 6 inches in length, and about half an inch in breadth, leathery in texture, and of a deep glossy green. The breadth of the segments and the deep hue of the whole frond contrast strikingly with the more finely-cut leaves of other kinds. It comes from the Polynesian Islands.

D. SOLIDA.—The root-stock of this is very stout, and it has a thick covering of rusty red scales, from amongst which are produced large, bold, triangular fronds from 2 feet to 3 feet long, and about a foot or more wide; the segments are large and massive, leathery and deep green. A stove Fern of noble mien from various islands in the Indian Seas.

D. PYNDATA.—This is a greenhouse Fern; it bears fronds from 1 foot to 2 feet in length, and upwards of 6 inches broad; they are three or four times divided, coriaceous in texture, and deep green. It comes from Australia.

D. PALLIDA, better known in gardens under the name of *D. Mooreana*, is a plant which no stove should be without. Its arching fronds are evergreen, from 2 feet to 4 feet in length, deltoid in outline, and about four times divided; the first divisions are large and densely clothed with obtusely triangular segments, which, when young, are suffused with pink, changing with age into a pale straw-green colour. It comes from the South Sea Islands.

TREES AND SHRUBS.

W. GOLDRING.

THE DWARF OR SCRUB PINES.

THERE is a certain group of Pines that are generally regarded as the outcasts of the tribe. They are considered to be neither ornamental nor useful, or, as some books have it, "they are quite unfit for arboricultural purposes in this country." It is on behalf of these Scrub Pines that I would write, as I consider that they have a value, and that not unimportant in ornamental planting. There are, roughly calculating, about a dozen of these pigmy Pines, most of them being mountain trees, rarely growing to the height of an Apple tree. The chief of these Pines are *P. Banksiana*, *Bolanderi*, *montana*, *inops*, *muricata*, *tuberculata*, *Cembra*, *pumila*, and *contorta*, but some of these are only dwarfs when growing in alpine regions, while in a temperate climate they grow to middle-sized trees. But it is these alpine dwarfs that I think are worth the attention of the planter, for they serve a purpose for which few other trees or shrubs are adapted. For instance, there can be no better object for a bold knoll than the common mountain Pine (*P. montana*). It is of dense growth, and makes a huge spreading mass seldom more than 6 feet or 8 feet high, is never affected by our hardest winters, and is especially effective during winter. Even the driest or the stoniest bank may be clothed with the mountain Pine, for it seems to thrive on the poorest soils. It is the same as *P. Mughus*, and *P. Pumilio* is similar. The Labrador Pine (*P. Banksiana*), which grows among barren rocks in Labrador and other northern regions, is another that may be planted in company with *P. montana*, and the foliage being of a different colour will serve to give variety to a mass. Of larger growth, but still suitable for knoll or bank planting, is *P. tuberculata*, a Californian tree, which is, moreover, interesting on account of its bearing its cones in crowded clusters, which remain on the tree throughout its existence. It is not such a hardy mountaineer as the two previously mentioned. *P. Bolanderi* is also

Californian, and rarely grows above 15 feet high. It is most desirable because its foliage is of a peculiar bluish grey colour, which renders it very telling in a group. Like *tuberculata*, it should be indulged a little in respect to situation, though if placed high and dry on a knoll or bank there is little to fear on the point of tenderness. *P. contorta*, which Douglas sent home from Oregon about fifty years ago, has its value on account of its peculiar habit of growth, which is more conical than that of most others, but it only reaches a small tree size. The Jersey Pine, *P. inops*, is a particular favourite with me, the green of its leafage is so different from that of others, and there is such a picturesque twist about its branches which, though it would offend the eyes of lovers of the formal among trees, would to many be the chief object of beauty. *P. inops* grows wild on the barren hills of New Jersey, where it is called the Scrub Pine. It is hardy enough for planting south of London, but in the midlands and northward it would perhaps be too tender. There are others which I should term artificial dwarfs, such, for example, as the dwarf Weymouth Pine (*P. Strobus*), a pigmy that has no character about it, being dense, tufty, and too squatly to be of much value; still, it may be appropriately planted with the mountain Pines. The dwarf variety of the Swiss Stone Pine (*P. Cembra*) is a true wildling, but, like the last, too stunted to be good for much; but as it has a tendency to assume a creeping growth, it may be useful for bold planting among bold rocks. There are various other dwarf Pines, but those I have mentioned illustrate the use to which I would like to see them put. A pleasing group could be made of these dwarf Pines alone which would be different from any group composed of other material. One of the best illustrations of this grouping may be seen in the Kew arboretum, where all the Pines I have mentioned may be seen in characteristic growth. In making a group of them, the taller kinds, such as *tuberculata*, *contorta*, *inops*, should be so placed that a pleasing and varied sky-line is formed from the tallest to the dwarfest. Another value the Scrub Pines have is the aid they give a planter in composing a group of tall Pines. In nine cases out of ten these are not successfully grouped, being generally planted all of a size, the result being a lumpy appearance; but by planting them on the outside of the group the abrupt outline of the tall trees is broken, and the group looks more like Nature's planting. I may be singular in my attachment to these Scrub Pines, but I am convinced that many lovers of trees would admire them also did they know them. All the Pines I have mentioned may be obtained from English nurseries, except the Labrador Pine, and this would be forthcoming if a demand for it sprung up.

Malus Halleana.—Will the writer of the note respecting this tree (p. 597, last vol.) kindly give further information about it? I, for one, am anxious to know where it is to be bought, and where it originates. "A. P." describes it as similar to *Malus (Pyrus) floribunda*; can he tell us if it is a variety of that species, or distinct? He says it is so much deeper in colour than *floribunda*, and if such be the case, it must, indeed, be a valuable shrub.—G.

The Red Dogwood is one of the few shrubs beyond Evergreens that attract one at this season. Its branches and twigs glow like sticks of red sealing-wax, and a mass of plants of it may be seen three hundred yards off. It is, without doubt, one of the most valuable of winter shrubs, and if associated with shrubs of a similar character, such, for example, as the golden barked Willow (*Salix vitellina*) its effect is heightened. It is the annual shoots that assume the brightest colour; therefore it should be the object to encourage these by cutting away the old. It will

grow anywhere, in any soil, and any position, but it is partial to a damp spot, where it grows rapidly. The true Red Dogwood is not *C. sanguinea*, as many suppose, but *C. stolonifera*, a native of the United States and Canada. It is spreading in growth on account of the numerous suckers it produces, and from which it may be propagated. The flowers and berries being inconspicuous are not worth considering, its sole value being the winter colour of its bark.

WALL SHRUBS.

JASMINUM NUBILOSUM is making an attempt to flower even during this bitter weather, and the advent of a few mild days would find it covered with golden blossoms. It is one of the most reliable of really winter-flowering shrubs, and on sunny walls in sheltered nooks it is seldom without some bloom. Much of its beauty, however, depends on the way in which it is pruned and trained. We like it best cut in a little in spring after it ceases flowering; the main shoots are then securely fastened to the trellis or wall, and the young growth is allowed to go on unchecked. Thus managed the shoots hang down furnished their entire length with blooms. *Garrya elliptica*, with its long bunches of tassel-like flowers, is a beautiful wall shrub. It is of stiff habit and rather slow growth; a sheltered nook near the house front, where the winter sun can get at it, is the proper place for it; there let it grow entirely unchecked. The buds of *Pyrus*, or *Ydonia japonica* are already showing colour. This shrub has a stiff thorny growth, and needs no pruning. *Ivies* of the variegated kinds are now in full beauty, and never show to such good effect as in mid-winter. The small-leaved kinds are the best for walls, as they may be grown so as to mingle with other things without smothering them, as the common Irish Ivy does; the golden blotched variety is especially conspicuous in winter. *Chimonanthus fragrans* is one of the few really winter-flowering wall plants that have scented flowers; the latter are not showy, but they make their presence known directly you approach the wall where they are to be found. They should have a full south aspect. *Coronilla glauca* is trained on walls in this locality, and flowers freely early in the season. It is generally planted in sunny aspects under the friendly shelter of overhanging climbers, and when covered with golden blossoms is very effective. *Euonymus japonicus variegatus* makes a very beautiful wall shrub, the variegation being strikingly effective in winter. *Escallonia macrantha* is one of the most popular of wall plants, owing to its bright rosy blossoms and shining foliage. It is seldom without some bloom on it even in winter, and is neat and compact in habit of growth. *Myrtilles* are capital wall shrubs, their scented foliage rendering them favourites. They succeed well on the south coast, and look bright after the rough gales which we frequently get here. The *Laurustinus* is used in all sorts of ways; on walls it flowers freely in winter during even the roughest weather, and when flowers of any kind are welcome. J. G.

Hants.

Darwin's Barberry.—Peaty soil is not generally recommended as being suitable for the growth of this beautiful shrub, but such, I am pleased to say, is the case, for seldom have I seen it in finer form, with more glossy ample foliage, and so well covered with flowers, as but a short time ago in a deep well-prepared peat bed. A hedge 50 yards long of the same plant backed the peat bed, and oh! what a sight this presented, the 3-foot-long shoots of a season's growth being literally crowded with flowers, while the shining deep green foliage told but too plainly that the plant was quite at home in its mossy bed. It is perhaps wrong of me to say that the bed was entirely composed of peat bog, for it was not, the mixture being about three-fourths peaty soil and one-fourth of road-scrappings, just such soil as American plants revel in. Some of the individual specimens were 7 feet in height, with heads 4 feet in diameter, the stems being from 3 inches to 5 inches across at the ground level. What surprised me most was how freely in such a soil

this Barberry reproduced itself from seed, for beneath and around these large specimens seedlings of varying sizes might be counted by the dozen, and we were shown several breaks containing hundreds of plants that had been lifted from beneath these gigantic shrubs and lined out in the nursery for planting in other situations. Let no one, therefore, who admires this pretty free-flowering Barberry, and can provide it with nothing but peaty soil in their garden, despair of cultivating it successfully under such conditions, for, take my word for it, if they will do but half as well as those I have just described you will be delighted, and recommend every friend to substitute a barrow-load of bog for his ordinary garden soil and plant a specimen of Darwin's Barberry. No doubt warmth is in favour of good cultivation, so if a sheltered corner can be provided all the better.—W.

Layering shrubs.—This is a simple and efficient method of getting up a stock of certain plants, or extending underwood generally. Most of our commonly grown shrubs come away freely from layers; notably the Laurel, Rhododendron, Privet, Mahonia, Honeysuckle, Bay Laurel, and hosts of others. Nursery layering consists in pegging down the outer and stronger branches in a circle around the stem of the parent plant, and, when these have taken root, cutting them away from their support and planting singly in any free soil, so as to produce a quantity of fibrous roots previous to planting out permanently. Layering for extending game coverts and underwood is but little different, only that the layers are not removed from the parent stool, but allowed to grow at will. In layering, it is best to disturb the ground with a spade around the parent plant, bend over the strongest shoots, and attach them to the soil by means of hooked pegs driven firmly down. A spadeful of soil, placed atop of that portion of the branch where it comes in contact with the ground, will materially assist in the formation of roots. Where the plants to be layered have attained to a large size, with thick, unyielding stems, such as frequently occur in neglected Laurels, Rhododendrons, &c., it may be found necessary, so as to assist in bending and pegging down, to saw the stem nearly through at a couple of feet from the ground. By so doing no injury whatever will result, plenty and to spare of sap ascending through the small portion left intact when sawing the stem. We have treated 30 feet high Laurels in this way, and the results were everything that could be desired, plenty of underwood now taking the place of what, previous to layering being engaged in, were tall, branchless stems, with only a tuft of foliage at the top. The hooked pegs should be made from Beech or Ash branches, and of sizes suitable for the various stems to be held down.—D.

Magnolia grandiflora.—Often enough perhaps are we accustomed to see abundance of plump flower-buds on this Magnolia, yet how seldom—here, at least, owing in a great measure no doubt to our unfavourable climate—do the flowers fully expand. This fact was never brought more forcibly under my notice than during the past summer when an unusually large specimen, that from year to year bore heavy crops of flowers which never became perfectly developed, opened fully numbers of its large, sweetly-scented flowers, the thick fleshy petals being thrown well back and revealing to full view the saffron-yellow stamens, which are so conspicuous a part of the flower. The individual flowers measured as much as 11 inches in diameter when fully expanded, were almost pure white with yellowish stamens, and deliciously odiferous. As a wall plant, this Magnolia perhaps does best, and shows off to greatest perfection on the Laurel-like leaves. It bears pruning well, and if planted in good, rich soil, soon covers a considerable surface, the branches being produced freely and ripening well off where the situation is at all sunny. The Japanese *M. Halleana* or *stellata* is, according to Mr. Ellwanger, of Rochester, and to whom I am indebted for the plant, a real gem, of dwarf growth, and remarkable for producing its flowers in early spring and

long before any other species. I have not seen it under cultivation; indeed, it is as yet extremely rare, but from Mr. Ellwanger's description of plants that have flowered in the Mount Hope Nurseries it must be the finest of its tribe, and that is saying a good deal. It forms a symmetrical bush of only a few feet in height, and as it is perfectly hardy and well adapted for the front of shrubbery borders, will soon rise in public estimation once it is distributed. Being difficult to transplant with safety, a little extra care is necessary in the case of *M. Halleana*.—W.

DECIDUOUS TREES.

Our ornamental plantations are deficient as regards deciduous trees. The lack of variety in them may perhaps be traced to the craze that existed some years back for Conifers; wherever an ornamental tree was required, a Conifer was selected, with the result that, whilst we are rich in evergreen trees, rare specimens of deciduous trees that thrive well in this country are comparatively scarce. Allow me, therefore, to furnish a short list of some deciduous trees that do well here. *Pterocarya caucasica* is one of our best. It is quick as to growth, handsome in foliage, and forms a fine shapely head. The rapidity of its growth may be imagined when I say that it was planted thirty-six years ago, and is now 45 feet high, nearly 12 feet in girth, and has a spread of branches 72 yards in circumference. I am afraid that it is hardly likely to last long in its present perfect state, as the growth is in many cases nearly horizontal and the wood brittle. It is also a fast traveller under the surface; its fibres have been found 25 yards from the main stem; it is, therefore, only adapted for large lawns, and should have a central position well away from all flower borders or beds. Quite a different tree is *Laurus Sassafras*; unlike the *Pterocarya*, it may be employed either on large or small lawns. It is pyramidal in shape, close in habit, and is a decidedly handsome tree. The foliage is dense and slightly scented. *Ginkgo biloba* is better known, perhaps, than either of the preceding trees, but it does not seem quite so much at home in our soil, the growth being erratic and irregular, and the general appearance of the tree rather unsightly; its unique foliage should, however, always find for it a place in good collections. The *Magnolias* are well known; it is, therefore, unnecessary to refer to them, except in the case of *acuminata*. This is with us by far the largest tree of the family, and makes a very handsome specimen; it grows nearly 50 feet high, and has a girth of 5 inches or 6 inches. *Gymnocladus canadensis* grows into a large tree, but its leaf season is, unfortunately, but very short—not more, under a cold, late spring, than four months out of the twelve; during the remaining eight it is naked and bare; still, it is quite at home, and may, therefore, be safely included in our list. Another Canadian introduction, viz., *Acer saccharinum* (the Sugar Maple), grows into a fine, shapely tree, and makes a handsome specimen; the foliage throughout the summer and autumn forms quite a distinct feature in the landscape; a large tree close to a Copper Beech formed during November a striking contrast to its dark neighbour. The two varieties of *Pyrus Sorbus* also make nice trees, both as regards growth and fruit. Although none of the trees just named require much attention, it should be remembered that a little is necessary in the early stages of growth, in order to lay the foundation of a good specimen. Thus where the subsoil is very sandy, hard, wet, &c., as the case may be, the hole for planting should be large enough to permit drainage to be worked in if necessary, and in all cases to allow for one or two cartloads of good new soil to be mixed with the best taken from the hole. With this precaution and all sides of the hole well loosened, the tree will have ample chance to get well established before the roots extend to the old soil; it is in fact a sound precept that an ornamental tree intended for a prominent position should have the same care and attention at planting as its neighbours in the

fruit garden. *Liriodendron tulipifera*, *Ailantus glandulosa*, and *Taxodium distichum* are all good as specimen trees, and the foliage of the last-named is very useful for decorative purposes.

E. B.

THE MONTEREY CYPRESS IN SUSSEX.

PROBABLY others besides myself have noticed that the neighbourhood of Tunbridge Wells seems to be particularly favourable for this tree, for no matter where it is planted, it appears to thrive with a vigour unequalled in any part of the south-eastern counties. It must be something in the climate or the soil, and possibly both combine to favour such growth. I lately visited the garden at SHERNFOLD, FRAIT, where this Cypress is the prevailing feature, towering above all other evergreen growth, and forming in some parts where at all thickly planted dense walls of foliage. Some of the trees must be 50 feet high, and most of them are feathered to the ground with branches. Among the dozens of fine specimens about the place there is a good deal of variation in habit, some being almost as thick through as high, while others shoot up into tall, slender pyramids; and this is mostly the case among those planted in the most sheltered parts; hence one may infer that exposure to winds, and shelter from them, play an important part in shaping the trees. These SHERNFOLD Cypresses are among the most remarkable sights about Tunbridge Wells in the way of trees. In an adjoining garden, ELY GRANGE, the Monterey Cypress is equally vigorous, and specimens which less than ten years ago were nursery plants are now between 20 feet and 30 feet high; in fact, they seem to outpace all the others. The soil is a sandy loam, resting on sandstone; hence tolerably dry and warm. At Bayham, ERIDGE, and many other places in the neighbourhood, this Cypress is the prevailing tree. At NEVILLE COURT, a beautiful garden just on the outskirts of the town, and laid out by Mr. Marnock, there is a pair of Monterey Cypresses, one on each side of the entrance-gate, which for height, spread of branches, and vigour are the handsomest I ever saw. They were, I believe, planted by Mr. Marnock; and perhaps he could tell us how long they have been planted, and a little about the soil they are growing in. G.

Forsythia viridissima.—In early spring when flowers are few this bright-blooming, hardy shrub just reminds us that it is not planted so extensively as an ornamental plant as its merits deserve. Of so hardy a nature—for even the dread east winds of our western coast cannot make it cease flowering—it is well adapted for planting in cold, exposed situations and in a great variety of soils. We have here several plants of large proportions that flower grandly from year to year, the bright golden flowers being produced, like those of *Jasminum nudiflorum*, before any leaves appear; fine specimens during March and April present a mass of floral beauty that is quite enchanting. Timely pruning is to be recommended in the case of this *Forsythia*, for as stout growths usually make their appearance after the flowering season, a nicely-shaped specimen is soon rendered anything but a beautiful object, unless by carefully removing such, and otherwise pruning into a desirable shape; but the plant is all the better for heavy prunings, its flowering capacity and dense free growth afterwards clearly pointing this out. Propagation of the *Forsythia* is easily managed by taking cuttings of well-ripened wood early in September and planting them in any free soil, and in a shady, northern position. Few plants are more amenable to training than the one in question, for it is just as easily managed to have a 6 feet-high specimen as a dwarf, procumbent bush. Planted against a wall and in fairly good soil, the *Forsythia* will before many years have attained to a large size, if nailing and pruning have been regularly attended to. Then, as a pot plant, it is of great value, for it is capable of being kept neat and in bounds by pinching and pruning, while it flowers freely during mid-winter if kept

in a cool greenhouse. Heavy loam, judging from our nursery specimens, seems to suit the Forsythia well.—W. A. D.

THE NEW PYRAMIDAL POPLAR.

The erect-growing variety of the Abele Poplar, introduced a few years ago under the name of P. Bolleana, is fast attaining the popularity which was predicted for it, as all the important tree nurserymen are working up large stocks of it, and this is a pretty good indication that there is a demand for it. No tree of recent introduction promises to be of such value for ornamental planting as this pyramidal white Poplar, as there is no other tree at all resembling it. It combines the upright growth of the Lombardy Poplar with the handsome leafage of the White Poplar or Abele in a remarkable way, and the fact of its being a hardier tree than the Lombardy adds greatly to its value. Judging by the largest trees in this country at the present time, it must be of quick growth. Some of these are 12 feet and 15 feet high, and these have been planted within the last six years; so that from this we gather that its growth is at the rate of about 2 feet in a season. Like the Abele, too, it is not particular as to soil, and no doubt will be equally suitable for planting in dryish places as well as in low, damp spots. One can imagine what a telling tree this new tree will make by-and-by when it gets to be as high as an old Lombardy, to which it will be a rival on account of its leaves, the silvery white undersurfaces of which are turned up to every slight breeze. No one need hesitate planting this tree, as it has had a fair trial now both in England and Scotland. The only fear is that it will be planted too plentifully, as the Lombardy Poplar once was, and produce a monotonous effect. It is almost as cheap now in nurseries as the Lombardy on account of its being easily propagated. It is increased by layers and grafting on the Abele—the most suitable stock. It comes from Tashkend, an out-of-the-way province in Turkestan, which may yet yield other valuable ornamental trees.

A new Ivy (*Hedera amurensis*).—In the Handsworth Nurseries, Sheffield, there is a new Ivy under this name, which, from all appearance, is a promising addition to the list of hardy Ivies. The leaves are large, quite as broad as those of *H. dentata*, but of different shape, being broad at the top, and deeply lobed. They are of leathery texture, and of a deep shining green. It is thought a good deal of by Mr. Fisher, who propagates it extensively. Every new hardy Ivy is a gain, and especially if it has such bold green foliage as this has, and at the same time is perfectly hardy. Coming from the cold region of the Amur River, there is little doubt that this new Ivy will be hardier and better for our climate than the other large-leaved Ivies.

The Golden-leaved Privet just now shows itself to advantage in the shrubbery, for it has come through the past few weeks of frost and snow perfectly unharmed, while variegated and golden *Euonymus* and other shrubs of a similar nature show unmistakable signs of injury. The Golden Privet is a neat growing shrub with small leaves closely set on the branches; being almost entirely of a rich golden yellow, it produces a bright appearance, and if set off by some dark Evergreen its effect is heightened. It is one of the few golden-leaved shrubs that can be depended on for winter; therefore it is a plant not to be lightly esteemed. It looks well if about half-a-dozen of different heights are planted in a group, but, as in the case of other variegated or golden shrubs, much is lost if advantage is not taken of contrasting them with green. This Privet is a variety of *Ligustrum ovalifolium*, and is known sometimes as *elegantissimum*, and also as *marginatum aureum*. The average nursery price for a good plant is one shilling.

The Holly-leaved Mahonia, always a beautiful Evergreen, is particularly so at this season when its foliage is stained with every gradation of tint from plum-purple to bronzy green, and the late spell of sharp weather seems to have intensified the rich hues

of the Mahonia foliage. There should be a good sprinkling of Mahonia planted in every garden, if only for the sake of its winter foliage, so valuable for cutting from for associating with flowers in vases. In a cool room Mahonia branches will last in water as long as a month or six weeks, and after that time will not appear the worse. In Daffodil time there is nothing that mixes so well with the rich yellow flowers as the bronzy leaves of Mahonia, and, later on in the season, when it regains its green summer leafage, it is always a good thing to cut and mix with flowers. Were we confined to one Evergreen, this Mahonia would be our choice, as it is not fastidious as regards soil or situation. The varieties of *Berberis Aquifolium*, named *latifolia*, *rotundifolia*, *Herveyi*, and *undulata*, are all different from the common kind, but certainly do not surpass it in the matter of foliage.

THE WEST LYNN VINERIES.

In October last, being at King's Lynn, I accepted Mr. Castle's invitation to see his Grapes; and at the outset I may say that, as regards crop and finish, I have never seen them equalled. After careful inspection, I may safely assert that there is not one bad Vine on the premises, all being robust and healthy. Among the different varieties the best appeared to be Gros Maroc, the bunches of which were simply magnificent. Next to this I would place Madresfield Court as seen here, its flavour and colour being all that could be desired, and the crop without one cracked berry. Gros Colmar, too, which must not be forgotten, was, I may say, unique. Let us, however, take the varieties *serifim* as follows:—

ALICANTE.—This variety covers one side of a 50-foot long house. It is on its own roots, and also grafted, and in both cases it bears very heavy crops and well finished, many of the bunches weighing 7 lbs. The Vines on their own roots are six years old, and several of them carry 40 lbs. per rod, and the Vines look none the worse for such heavy cropping, *i.e.*, if laterals and foliage are any criterion. Nine Vines, two years old, are planted in a Cucumber bed, a house which the sun does not touch till nearly noon, and it is astonishing how well they have done in every respect, though the depth of soil is only 15 inches and the bed is only 3 feet wide. The Alicante, grafted on the Black Hamburg, does well, but the crop is much too heavy, eighteen bunches being on a rod, and the bunches not less than 2 lbs. each.

ALNWICK SEEDLING.—On one rod of this there were twenty-three bunches, and the variety always commands attention on account of its deep blue colour. It ripens early, and keeps fairly well—*i.e.*, until April. It requires special attention at blooming time; it sets well with pollen taken from Lady Downes, but water for setting this variety is a fallacy. The syringe was used very freely on one bunch, but to no purpose. The caps of this Grape require rather hard treatment; a good feather brush is just the thing to use on it. The flesh of the berries of this Grape is very highly coloured, and the flavour also is very superior. It is not a very strong grower; growing, as it does here, side by side with Alicante and Lady Downes, the difference between it and these sorts is very striking.

GROS GUILLAUME this year has borne nothing but small bunches, 5 lbs. or 6 lbs. being the heaviest, while in other years bunches have been cut up to 3½ lbs. This crop is, however, likely to be a good keeper, and here it fruits as freely as a Black Hamburg. Mr. Castle is, however, gradually cutting it out, not on account of its not doing well, but because it does not pay, and, singular as it may appear, there is always more difficulty in colouring it than any of the other Grapes grown at West Lynn—this, too, with a much lighter crop.

BUCKLAND'S SWEETWATER seems to be quite at home at West Lynn, and is a noble, early-ripening Grape, and one which always commands attention on account of its size, colour of berry, and good cropping

qualities. In order to show how extremely fruitful this variety is, I may mention that there is a bunch on every lateral, and that, too, under Black Hamburg treatment. Their quality, however, does not improve by keeping.

GROS COLMAR—This is a very trying, yet a most profitable Grape, and one grown in larger quantity here than any other. One span-roofed house 50 feet in length is filled with this Vine entirely on its own roots, and it always produces satisfactory crops, the berries being good, but their colour sometimes not what it should be. Some are, of course, a good black, but a good portion is not so. In mixed houses this variety is, as a rule, very unsatisfactory. What appears to be required to ripen or rather colour this Grape is starting it early, using fire freely, and giving plenty of ventilation so as not to force it unduly. This variety, grafted on the Muscat of Alexandria, has proved to be very good indeed; some have said that on this stock the colour would be bad, but some of the blackest are on Muscat stocks. Certainly if overcropped, bad colour will be the result. This year for the first time the foliage of this sort has been good, none of the leaves being curled. Liberal feeding, early starting, more fire heat than usual, and more ventilation are doubtless the cause of this. Avoid coddling if you wish to get good Grapes. When growing the transparency of its berries is very striking.

GROS MAROC.—This is a profitable Grape either grown on its own roots or grafted. Although grown in the worst position at West Lynn, it is the first to colour, being before even the Black Hamburg, but it is not really the first to ripen. Here it fruits just as well on the old rods as on young ones. When grafted on the Black Hamburg it is very superior as regards flavour. The crop, too, is heavy; in one case 40 lbs. were taken off a last year's rod. On grafts more thinning is required, especially if they are to hang long. This grafted on Buckland's Sweetwater is a really fine Grape, the berries of which are the largest of all, but by the beginning of December they begin to shrivel. It grows very robustly and fruits very freely. As a market Grape it is worth as much again as the Black Hamburg, and it is ready at the same time.

LADY DOWNES SEEDLING.—This has produced a faultless crop, every lateral being fruited, and some of the best bunches are on laterals, on which there are often two bunches; in fact, if a pair of bunches were wanted for exhibition, a pair on a lateral would be selected. This variety is grown here in the form of single rods, two rods and three rods to a Vine, all at 3 feet apart, with this result, that the three rods in every case are the best—this, too, with the same number of bunches on each rod, *viz.*, two dozen. The fruit on the single rod, however, coloured first. Scald in some places affects this variety, but here two dozen berries would cover the loss in this respect. The sun is said by some to be the cause of this disease, for disease it is, but all the berries attacked here are so placed that the sun cannot touch them; indeed, they are quite in the shade. If this variety is started gently in March and steadily grown on, keeping the fire in all through the season until the Grapes are cut, much sounder and better Grapes will be obtained than under any other treatment.

MADRESFIELD COURT.—The crop of this at West Lynn is too heavy to colour well, but then there is no cracking. The two Vines of it grown here have for three years each carried 26 lbs. per year. Some 52 lbs. have been sold, and still 30 lbs. have been left hanging. The berries and bunches are good, and, having cut so many to lighten the Vines, the remainder will be kept for a month. This is not, however, a good keeping Grape, but, owing to the position of the Vines, special ventilation can be afforded them. The treatment is precisely the same as in the case of Gros Colmar up to colouring time; but as soon as there is the least tinge of colour visible tepid liquid manure is given; then a slight layer of rotten manure is applied, firming it fairly well down, then over the whole is put a layer of Grass and straw about 6 inches deep. From the day on which this covering was used, *viz.*, 1st of August, no water has been given to the inside border. This being the

fourth year of such treatment, it can be asserted safely that such treatment does not injure the Vine.

So far the roots have only been dealt with, but, of course, ventilation is a very important point, especially top ventilation, which is continued all night after colouring time. Laterals are stopped all through the season, keeping them well away from the glass; if a leaf touches the glass moisture is condensed, a drip is created, and should a drop of water fall upon a bunch the berries crack. Spider, too, especially at this season of the year, is troublesome if not well kept under. It has been said that Madresfield Court is not a good keeper, but it will keep to the end of November. Madresfield Court grafted on Gros Colmar here lost its fine flavour, but coloured well. Both bunches and berries were, however, small, but the graft is not strong. As regards flavour, Madresfield Court cannot be beaten, and as much as 40 lbs. of sound fruit have been taken from one Vine. By placing Gros Maroc at the top of the list I shall doubtless be found fault with on account of its flavour, but it must be remembered that Mr. Castle's first point is hard cash. Madresfield Court is certainly very superior to Gros Maroc in flavour, but, unfortunately, it comes to an end before or by Christmas, whilst Gros Maroc keeps through March, and at that season it made last year from 7s. 6d. to 10s. per lb. These prices are not given at random, for I myself saw the returns. R. GILBERT.

Burghley.

* * Mr. Stephen Castle sends us specimens of his Grapes, packed in a very simple way in a basket, with wadding round the outside, and the bunches simply attached and resting quite loosely in the basket, except, of course, on the side which supported their weight. They come in as good condition as if just taken off the Vine—perfect bloom, large berries, and delicate flavour. Such a mode of packing would not do if they were rolled over, but it serves very well so long as the basket or whatever they are sent in is kept in an erect position.—Ed.

MARKET GARDEN NOTES.

A FEW days since, when the north east wind was blowing intensely keen over the fields and it was freezing sharp, I watched a couple of men engaged in preparing Rosette Coleworts for market. A colder job during keen, cutting winds could hardly have been found, and as the half-frozen greens were, of course, exceedingly brittle, the effect upon the Coleworts was far from being beneficial. One man pulled the plants, and in doing so gave each stem a half twist and pulled off some of the outer leaves; then he threw them on to a table which was, of course, anything but clean. The second man stood on the windward side of the table, and gathered the plants into bunches by the stems. Grasping the roots with the left hand, he gathered in the Coleworts with the other, pressing into each bunch as many as the hand would well grasp; he then bound them up with a withy and threw them on to a heap behind him. I could not but note how much the heads suffered from this method of preparation, getting dirty as they were roughly turned over from side to side in the making up, and very much torn and bruised. I should say that after bunching these greens seemed to have deteriorated 40 per cent. as compared with their appearance before pulling. Naturally, I enquired whether it would not be far better to cut off these Colewort heads cleanly and place them in baskets as fast as cut, and was told that it would be so, but that the London trade would not so purchase them, but would have them bunched only, although thus damaged and dirtied. This is a sample of the kind of despotism under which both producers and consumers of market vegetables suffer at the hands of the trader or shop-keeper class, which insists upon all this trouble being taken for no other reason than that it is the custom to buy and sell winter greens of this character in bunches, and no other plan, even though preferable in all respects, will be accepted. Beyond the injury done to the Colewort heads the

work of bunching is considerable, the bulk to be sent to market is much greater than it should be, and not least, not only are consumers burdened with all this useless matter of stems and roots, but local authorities have finally to remove it again back into the country in the form of rubbish. Some day, perhaps, a strong local authority emanating from metropolitan municipal institutions will interpose and decline to admit useless lumber, in the form of stalks with excessive leafage, to be brought into London, as not only relieving local authorities of preventable labour, but also minimising danger to the public health from excessive accumulations of refuse and garbage. Common sense, as well as regard for quality and cleanliness, urges that all kinds of small greens should be sent to shop or market only in baskets, and it is certain that so sent they would be much fresher and cleaner for consumption.

Generally I notice that whilst the long spell of frost and heavy snowfalls have not appreciably injured all ordinary green stuffs, all which have hearted in, whether Cabbages or Coleworts, show most damage; many of the firm white hearts, being much seared and under a quick thaw, will no doubt soon decay. Even now this frosted material has a strong flavour. Most of the larger Cabbages, especially Drumhead Savoys, are past marketing, and must be either sheep-fed or be cut to pieces and ploughed in as manure. Early planted Cabbages, which made too much head through the long and open autumn, will probably cut up badly under the influence of March east winds; but, so far, all the later plantings, even in soil so saturated with water that with even a crust of frost upon it will at present hardly hold a man up, consisting of sprouting and white Broccoli, so far, have stood very well. This class of green stuff seems always to suffer most when subjected to keen biting winds, which literally burn or wither up the leafage.

BRUSSELS SPROUTS are not in such good odour this season as in some previous years. I hear numerous complaints of burst or expanded Sprouts, this form of them being seen in large patches, causing much loss to growers. It is evident that there are some bad stocks about, consequent upon the cutting prices of the seedsmen. There is no member of the Brassica tribe which it is more important should not only be true, but should be good, than Brussels Sprouts. It is doubtful, because of its origin, whether any other member of the family sooner deteriorates if not well placed and grown free from association with all others. When the produce of a given batch may be perhaps 1000 bushels, it is obvious that if a shilling per bushel be lost by a bad sample the total loss is great—indeed, makes all the difference between paying and losing.

There can hardly be a better strain for market growers in the open field than Exhibition, Matchless, King of the Market, or under whatever name the large, solid-sprouted kind now so much grown in private gardens is known. Whilst productive of large stems and sprouts, under the high class culture found in private gardens, in the field the growth and sprout production seem to be all that can be desired. Really big sprouts, such as too often find favour in exhibition collections of vegetables, will not suit the market at all. A good, solid, medium-sized sample invariably finds a ready and profitable sale, but such samples are far from being plentiful. I saw a fine breadth the other day of a really capital stock, called Myatt's Brussels Sprout, and it was specially noticeable because so much above the average. The grower said that he gave rather a higher price than ordinarily ruled for the seed, but it paid far the best in the end. The plants were about 20 inches in height, and bore fine crops of clean, solid, medium-sized sprouts. A. D.

MR. JOHN F. M. ELROY, for the past eight years secretary of the United Horticultural Benefit and Provident Society, died at the gardener's cottage, Moray Lodge, Campden Hill, Kensington, on Sun-

day, the 9th inst., after an illness of only two days. On Friday, the 7th, he was seized with a fit, but happily kept conscious to the last. He had lived as gardener to Mr. A. J. Lewis, at Moray Lodge, for twenty years, and during that time effected many improvements in the garden.

We have also to record the death of Mr. R. LAING, nurseryman, Twickenham, at the age of seventy-seven. Mr. Laing was for years a grower of all the better kinds of Roses; but latterly, owing to his surroundings having become altered, he was obliged to turn his attention more to florists flowers and plants under glass. He was a prominent committeeman of the Twickenham and Richmond Horticultural Societies, and was also a warm supporter of the Gardeners' Benevolent Institution.

WOODS & FORESTS.

THE CORSICAN FIR.

PINUS LARICIO is a very good name, botanically, and it is a name which writers are fond of using, but the best way is to call this Fir by its English name, viz., Corsican Fir, and then there can be no mistake. Most people, who are not foresters, have been familiarised with the tree under this name. I notice (p. 39) that "A. D. W." claims to have "all along strongly advocated the extensive use" of this Fir, which is probably the case, although I have never seen any of his frequent communications on that subject that were published before the character of the tree began to become known through the medium of *Woods and Forests*. This publication may take credit, I believe, for having done more to popularise the Corsican Fir among planters, and familiarise them with its habits and qualities than all the previous writings on the subject put together, and the result is becoming plain. I like to put the saddle on the right horse. The Corsican Fir was introduced into this country about 130 years ago. It has been familiar to our foresters during a great portion of that period, and has been planted to a moderate extent by a few proprietors, but you may travel for days over estates and never see a plantation of it. Some, who profess to see its value now, have all along been planting Spruce and similar worthless subjects instead of the Corsican, and you may hunt for years through the writings of those who have written regularly on forestry without finding more than a passing reference to the tree. Until *Woods and Forests* and *THE GARDEN* took it up the general reader knew little about the tree, and there has been literally a scramble for it since in the trade, so far as my information goes. It was Larch, Larch, Spruce, and Scotch Fir, with now and then a few Austrians thrown in; but the Corsican Fir, because it was difficult to transplant under some circumstances, and because it was not known, was neglected. Dignified arboricultural societies, north and south, have continued to write their humdrum essays on a variety of topics, consigning the same to the oblivion of their "transactions" as fast as they were written, and they have pilgrimaged all over the country in search of arboricultural knowledge, but they never appear to have stumbled on a Corsican Fir that impressed them in the least as being a tree of special value. I see the Scottish Arboricultural Association has woke up to the necessity of offering a prize next year on "the comparative value of the newer Coniferae as timber trees in Great Britain," but how late in the day! The question has been practically settled, and we predict the essay will put the Corsican at the top of the list; for, though introduced so long since, it is still new as a timber tree. If the essayist does not do this, it will be because he does not know his subject. Considering the state of our woods in England, where they are neglected, and in Scotland, where they are so skilfully managed as to become a burden to the proprietor, one has little or no patience to speak of societies that have, with the best of opportunities, done so little good work, save in indulging long-winded harangues delivered periodically.

The prize offered by the Scottish Arboricultural Society for an essay on "The history and details of the plantations on an estate for a period of not less than twenty years, giving the acreage, annual receipts, and expenditure per acre," ought to be instructive if it can be got; but in judging such a production the utmost care is necessary, and nothing should be accepted that is not vouched for and made clear to the last detail. I, for one, would like to see some of the so-called well-managed woods in Scotland subjected to such a test. I am informed from good sources that few will stand it. One safe inference may be drawn from the ample prize list of the Scottish Arboricultural Society: the members have evidently been reading up on their own account, and endeavouring to realise where they are. The prize above alluded

to—one on the comparative merits of Coniferae raised from home-grown and foreign seed, one on the natural reproduction of forest trees from seed, and another on "the timber grown in Scotland and its uses"—may lead to something if taken up by competent hands, and are all subjects recently suggested in *Woods and Forests*. What on earth the society wants an "original plan for the erection of a forester's cottage" for is more than one can fathom. Foresters, I opine, are like other people, and need no special provision in the shape of a habitation; what, therefore, the society has in its eye is a mystery. If it had been a bark shed, a saw-mill, or a work-shed one could have understood it, but an original plan for a house for a forester!

YORKSHIREMAN.

PREPARING ENGLISH FIREWOOD.

WHERE a stock of wood has been placed under cover, spare hours during bad weather may be devoted to its preparation for use. When the logs are not very large, of whatever kind of wood they may happen to be, it is often best to have them cross-cut by a hand-saw. With a fairly sharp saw of the right character, which should be stiff in the blade, but not too thick, with a coarse tooth set wide enough to allow the blade to work easily, a good deal of cutting may be accomplished by a handy man in a few hours. The amount of labour which is often wasted upon ineffective saws is simply astonishing. It is not to be expected that an ordinary labourer will be sufficiently up in sharpening to keep a saw in going order, as to sharpen a saw well is a comparatively rare accomplishment, but it will well repay all concerned as soon as the teeth go "dead" to see that the saw is at once re-sharpened. For general firewood cutting directly across the grain, when two men are employed, there are few saws superior to the fish-shaped saw with M teeth. This works both ways with a minimum of friction. As to the best mode of fixing the wood whilst the operation of cross-cutting is carried out, for small logs cut by the one-man saw there is nothing better than a framework made of small Oak scantlings constructed to hold the logs whilst they are being sawn. This is familiar to many as the firewood-sawing horse. Two small scantlings are crossed at each end, and these ends are fixed together by means of a square scantling passing from centre to centre of each cross, and further strengthened by longitudinal scantlings nailed to each side. The centre of the framework where the scantlings intersect should be about 2 feet from the ground or floor. The crossed scantlings form a fork at each end of the horse, and in these forks the logs to be sawn are laid. With regard to the larger logs which have to be cut with the two-men saw, it will be easier to fix them to rough transverse scantlings laid upon the ground by means of dogs, or, in other words, iron or steel bars bent and pointed at the ends so as to retain a firm hold when driven into the scantling and the log. This method of treatment will be much the same whatever the wood may happen to be, but the tools used and subsequent splitting will vary according to the size of the sections and the readiness with which they can be cleft. With such woods as the Oak, Beech, Ash, Birch, &c., when tolerably clean and free of knots, a good-sized axe will answer the purpose, but with logs of Elm and other woods which are rough and knotty the beetle and wedges will have to be requisitioned. Tree roots make good firewood, but they entail a lot of labour in removal. To lessen this a good deal has been said about the use of explosives, but in the generality of cases these will not be resorted to. A better plan is to employ a few men, paid according to the amount of wood they remove at per cord or per load. The roots of underwood stools can be removed at a price per pole, either simply by cutting off the roots a few inches below the ground level and removing only the centre of the stool and leaving the remainder to decay, or by the more elaborate and costly process of grubbing up the whole and leaving the ground in a condition for planting. In any case there are but few estates where, by the exercise of a little thought, a good supply of wood fuel is not to be had.

D. J. Y.

Dry rot.—It has been ascertained, says the *Lumberman's Gazette*, that timber which has been floated in water for a considerable time is no longer

liable to the attack of dry rot. The albumen and salts slowly make their escape from the wood, thus depriving the fungus of the nutriment needful for its development. A French experimenter has shown that fresh sawdust rots away in a few years in damp earth, whereas sawdust from which the soluble matters have been soaked by water remains unchanged under like circumstances.

BENEFITS OF SHELTER PLANTING.

SCOTCH plantations are chiefly in masses, clumps, or belts. The first of these is almost the only form in which we can pretend to anything approaching to the picturesque; for here the fence of the plantation may be entirely or nearly kept out of sight, while in the two latter modes this is almost impossible. If a plantation is made for beauty and profit, as regards wood, the mass is certainly the most desirable; but the clump and the belt are by no means destitute either of beauty or usefulness; indeed, as regards the latter quality, I will venture to say that in many districts the country has been benefited 50 per cent. or 100 per cent. by the numerous belts stretching their protecting arms around what are now lovely green pastures, but before the encircling strips were formed were barren heathy uplands. Clumps and strips of plantation, too, come within the limits of many a one who cannot give land for a mass; and if a little persuasion would induce proprietors to carry this most useful improvement a little further, one object of this epistle will be gained.

Our severest blasts of wind here are from the south-west and west, as may be seen from our trees bending to the east. Our belts, therefore, as far as practicable, run from north to south and from north-west to south-east, though this is of course varied by situation and convenience. They ought never to be less than 60 yards wide, and if 20 yards or 40 yards more can be added to their width, the shelter will not only be greater and the wood better, but they will look much handsomer; and if they are wide enough to allow a roadway along the centre of the belt, it will be found a great advantage, both in giving access to the wood for carting, when it is of a size fit for useful purposes, and also when it is young, in affording facilities of inspecting the wood with a view to thinning, which, alas! is so much neglected. Most proprietors know the advantage of a march fence; they would, in many cases, find it greatly to their benefit and not much more expensive to have a march strip, for which each coterminous proprietor should give 40 yards or 50 yards, having a road in the centre along the actual line of march, or it might be more convenient if the strip were for so much of its length on one man's land and so much on the other. By this latter mode, each would be able to thin his own wood to his liking; and this is of greater consequence in a strip than in almost any other form of plantation, and in strips is almost always neglected.

THINNING.—I do not think I could name ten plantations in the south of Scotland where the trees are sufficiently thinned; and the reason you always get for its not being done is, "Oh, the trees are of no use as wood, and they make excellent shelter." Now, in the first place, what is the use of planting thick? It may be said the trees shelter one another; this is a mistake as regards young trees, for by the time a tree is big enough to afford shelter its neighbour is as large, and can give as much shelter as it can; then the expense of thinning, when the trees are worthless, is considerable, and it requires a bold hand to cut down a fine thriving tree. I would say, therefore, if you have not courage to thin (though I am rather an advocate for thick planting), plant sparingly. In belts it is peculiarly necessary to thin. A belt is planted for shelter; and for twenty years perhaps, though that is the utmost limit, a belt, planted as thickly as it is generally planted, will form a good shelter, but after that period the shelter becomes less and less. The trees come to be without a single branch on the stem for 10 feet upwards at least; they are unhealthy, their roots being choked; the wind makes fearful havoc among them, and at the end of the second twenty years there will be but a few stragglers left to tell the melancholy fate of their departed brethren:

and, observe, these stragglers are on the outside of the belt, and possibly on the most exposed side, but where they have had a little more justice in point of room, and got accustomed to the blast. But if a belt is thinned so that the lateral branches barely touch one another, the trees become feathered nearly to the ground, and a dense mass of foliage or branches remains to arrest the progress of the wind, and the desired shelter is gained. The trees, though not so tall, are healthy and in a more natural state; their roots have room, and they stand their ground amid the winter storms, which with us are neither few nor far between.

A great objection to planting being carried on more extensively than it has hitherto been is the great expense of enclosing. In pastoral countries "a dry stane dyke" is almost necessary. English readers, or some of them, may require to be told that this is a wall built of stones without mortar. It is generally about 4½ feet or 5 feet high. This, as above stated, is the most expensive part of the plantation, but one of the most important; if good durable stone is to be had in the immediate neighbourhood in spite of the heavy outlay, it is the cheapest, the most durable, and satisfactory fence in the long run. But a great many plantations have been made with no other fence than a ditch and turf wall, or as we call them "feal-dykes," with a single railing of paling along the top. This is a cheap fence and is put up, paling included, for about 1s. 6d. per rod. The cost will scarcely be a year's interest of the outlay on a stone dyke; but it requires constant attention, as cattle are apt to rub it down, and sundry other misfortunes happen to it. However, with a very moderate degree of care it will answer, and in many situations has answered, all the purposes of the stone dyke, and, so far as appearances go, it is much prettier to look at. I do not, as a rule, approve of sowing Whins (Furze or Gorse) on these dykes, for, unless they are regularly switched, they spread into the adjoining fields, and become a great nuisance, and are often destroyed by frost.

DRAINAGE.—Draining is requisite in a plantation, which also is much neglected; by draining, I mean particularly surface drains; these can be made at a very small cost; about 1d. a rod for the ordinary sheep drains, which they resemble, 20 inches wide at top, 14 inches at bottom, and about 12 inches deep. The benefit of these drains is immense in drying the ground, and it is worthy of attention to observe that along the line of drain, upon the stuff thrown out the trees beat their neighbours; and you can often follow out the line of drain by looking along the tops of the young trees, which in the above situation are so much more vigorous than their neighbours, that they sometimes resemble a hedge on a bare part of the plantation.

If a stone dyke is made, there ought to be, in about every hundred yards, a set of steps, forming a stile, for crossing into the plantation. This will be found a great saving to the wall, if sportsmen and their dogs are in the habit occasionally of following game into it, for both man and dog will prefer the easiest point for getting over the fence, and they will not pull down a stone or two every time they pass, to the danger of their legs and the detriment of the fence. Young plantations are a great shelter for hares, and if it is wished to give them access, let pens or conduits, 12 inches by 9 inches, be made also, every 100 yards or 200 yards, in the dyke. Neither these nor the stiles will add a sixpence to the original contract price of the dyke. Let these pens or conduits, however, be shut up in autumn whenever the corn is cut; as when the hares lie in the plantation, and feed out of it, they are easily snared on the runs leading to the pens. The pens for the hares should be opened about the beginning of March, and the keeper should look sharp to them. Any gate to the plantation should be boarded, so as to prevent hares passing in or out; for if this is not done, it is the poacher's harvest field with his net. During the months of October to March, inclusive, the hares will take the dyke at any part when they wish access, but the young ones are not able to do it. The pens are useful also for young partridges and pheasants passing to and from the cover. H.

How to prevent splitting in the ends of timber when it is being seasoned is a matter now engaging attention. According to a recent report, it has been ascertained, says an American paper, after trying a number of expedients, that by painting the ends of the timber with thick glue several kinds of timber can be dried without splitting. It is supposed that the glue penetrates far enough to cement the layers of the wood together near the ends, and thus keeps the ends from drying faster than the rest of the wood. Of course, this method requires seasoning under cover, since rain would have the effect of dissolving the glue.

Firewood and wood fires.—As I burn nothing but wood in five rooms of my house, I hope you will allow me to say a few words on the subject. The fireplaces are circular; formerly they were square-backed. My father altered them to their present shape, which increased the heat in a marked manner. We have dogs in all the fireplaces. The wood we burn is Oak, Beech, and Ash. In the servants' hall, which has a slate floor, Fir is burnt. The back sticks are, of course, green. The best wood for these is Poplar, which is the least inflammable of all wood. The wood is cut up by a circular saw, worked by water power. As far as heat, appearance, and comfort goes these fires are far superior to those of coal. We never remove the ashes except when absolutely necessary; then only a small quantity is taken away. Of course there is a great deal in the management of the fires. They require constant attention; in this respect they are not so convenient as coal. However, I find servants soon get into the way of them. For cleanliness they are, of course, far superior to coal. The best wood is, without doubt, Ash. The old saying—

Ash green,
Fire for a queen.

is a very true one. Spanish Chestnut is the worst wood there is for flying out. We have always one year's stock in hand. The wood is all stacked and thatched.—REGINALD KELLY, *Kelly House, Liffon.*

Pinus Sabiniana.—This beautiful glaucous, grey-coloured, long-leaved Pine was introduced into Britain from Upper California in 1832 by Douglas, and was named in honour of Mr. Sabine, then secretary of the Royal Horticultural Society. Douglas describes the trees in their natural habitats as being "of tapering form, straight, and of regular growth, from 40 feet to 120 feet in height, 2 feet to 12 feet in circumference, and, when standing far apart or solitary, clothed with branches to the ground." Some few reach 140 feet in height, but those are not of great circumference. The wood is white, soft, even-grained, and perhaps not very durable. The leaves are in threes, very rarely in fours, from 11 inches to 14 inches long, and drooping during winter. Since its introduction this tree has become extensively distributed throughout the country, but, as a rule, it has not succeeded well; indeed, it has been a most disappointing tree, except, perhaps, in a few favoured localities. At Holkar, in Lancashire, there is a fair specimen of it, and at Kew, too, it is succeeding tolerably well. Where it does thrive and grow vigorously, and when it is clothed with its long, glaucous, drooping foliage, it is an object of singular beauty, distinct both as regards feature and form. It is highly ornamental planted as a specimen tree in pleasure grounds or in the foreground amongst other Conifers of darker foliage in a pinetum. It should be planted in sites quite sheltered from cutting and prevailing winds and where there is a good depth of rich vegetable or alluvial deposits; when planted in thin, poor soils and exposed to winds, it presents a ragged, miserable appearance, and its branches gradually become, as it gets old, almost divested of leaves; indeed, in such positions it has been known to perish outright. The idea, therefore, of *Pinus Sabiniana* ever becoming a useful timber in this country may be at once discarded. Its cones, it is said, are very remarkable, being about 12 inches long, and rough and prickly on the outside; they grow in clusters round the branches, are recurved, press on the wood for support, and remain on the tree for several years. Statistics from any of your readers who may possess or know of good specimens of this tree would be interesting, stating age, height, present condition,

soil, or geological formation, or any other particulars as to habit and suitability of climate.—S.

SEASONABLE WORK.

TAKE advantage of mild, open weather to push forward planting operations as vigorously as is consistent with the proper execution of the work. All dry, warm soils should be planted in autumn, but stiff clayey land and deep peat bog which retains an excess of moisture had better not be planted till spring. On such situations Black Italian Poplar, Goat Willow, Huntingdon Willow, Bedford Willow, Alder, and Birch may be planted with success, and as there is always a demand for this class of timber, it soon turns into money. As the different plots of ground are cleared of young trees, lose no time in having the ground dug into rough ridges, which will not only keep it dry, but also expose it to the influence of frost, which will renovate and prepare it for the next crop. In places where the soil is of a poor, thin nature, take advantage of frosty weather to cart and apply a dressing of good loam in order to improve it. Turn over compost and manure heaps, so that they may be ready when wanted.

The cutting of underwood should be finished as soon as possible, after which thinning the timber must be proceeded with, care being taken to mark all the inferior, unhealthy, or badly shaped trees that are likely to interfere with the full development of the better ones that are intended to stand permanently. In cutting young plantations for the first time, great care should be taken to use only good cutting tools, and to finish off the work well. In thinning screen plantations, the workman must, to a great extent, be guided by the depth or thickness of the belt. When it is narrow the removal of any considerable number of trees would mar its effect; but when its extent will permit of such treatment, the best way to secure a permanent screen is to keep the front trees well thinned out from the commencement, so as to allow them to branch low. By such means also a gradual increase in the height of the trees from the front line to the centre is secured, as those in the interior, from being more crowded, are the more rapidly drawn up. In felling heavy timber, which should be one of the principal occupations of this month when hands can be spared, the cross-cut saw should be used in preference to the hatchet, which will not only prevent unnecessary waste of timber, but also give the timber a better and more marketable appearance when put up for sale.

Cutting and cleaving cordwood and grubbing hedges or levelling banks are operations that can be done when the ground is covered with snow. Young plantations and ornamental trees and shrubs should be gone over to see that no injury is done by ground game, and any plants that have been nibbled or barked should be "bushed" by tying Heath, Birch spray, or Fir boughs round the necks of the plants; this will be found a safeguard against further injury for two or three years. Even if the plantations or specimen plants are protected by means of wire netting they will require attention to see that rabbits have not made inroads, as they frequently do during frost and snow, by scratching holes underneath the fence, and when pushed by hunger they frequently bite holes through wire netting. Nursery work, lifting and planting trees and shrubs, making and planting cuttings, digging ground that has been cleared of a crop, should now have attention.

Now is a good time to scour out all open ditches in plantations, and to distribute the soil evenly among the young trees, as by this means the fallen leaves are at once fixed, so that they decay on the spot, instead of drifting and filling up the watercourses, or choking pinnocks or culverts. New ditches should also be cut where required. Though great attention is paid to letting off water from young plantations, the ditches are often allowed to fill up as the wood gets older, but as the roots of trees penetrate deeper into the soil the necessity for removing stagnant water increases, and instead of the watercourses being allowed to fill up, they should be gradually deepened. This is more especially the case with plantations of Larch and Spanish Chestnut. Unsoundness of timber is frequently caused by the presence of too much water in the soil in which it grows.

No. 793. SATURDAY, Jan. 29, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

NOTES FROM MADEIRA.

A VISIT to this lonely island, far out in the great Atlantic Sea, will prove of great interest to all flower-lovers, more especially so, to my thinking, if they are already familiar with the gardens on the Riviera, for the very likeness only accentuates the differences that really exist. A difference of 10° in latitude must needs tell on vegetation; and, in consequence, everything that manages to survive the too frequent frosts or bitter winds of the Mediterranean shore here grows luxuriantly without need of protection. Many tropical shrubs and trees are also added to the flora. Three weeks of brilliant summer weather to greet a new-comer who arrives in mid-December no doubt predisposes to admiration; but I think that those who shiver at home under penitential skies of leaden grey will understand the charm of finding the turf on the mountain-sides (when over 2000 feet above sea-level) carpeted with white Violets and starred with dwarf rose-coloured Oxalis (*O. venusta* and *purpurea*) which on New Year's Day feasted both eyes and nose. Lower down, where water for irrigation may be obtained, the Peach orchards present a most unexpected sight, for here they flower before the leaves of last autumn begin to drop, and quite outrage all our gardening ideas of propriety by showing that they need no winter's rest to enable them to flower and fruit abundantly. From an artistic point of view this behaviour is much to be commended, and for the future I would advise rising artists to add apple-green and red-brown leaves in abundance to their studies of Peach blossoms. Another contradiction to all our northern ideas may be found in the Apple trees, which are also in full flower; while clusters of rosy-checked Apples and deep green leaves are to be found on the next or even the same bush. It is to be remarked that Pear trees do not thrive here, while the hardier Apple succeeds so well, only confessing by its white flowers, which have no rosy tinge such as we are accustomed to, that a cooler air would be more congenial to it. Lower down and nearer the sea precocious Fig trees are putting out fresh leaves to greet the new year; Aloes are blooming in thickets of orange Lantana bushes and red Geraniums; and everything proclaims that here at least there is no such thing as winter. The avenues of Planes and Oaks—which by some curious inversion of taste the Madeirans have planted largely, to the exclusion of their own beautiful native evergreen trees, the Til (*Oreodaphne foetens*) and the Vinhatico (*Persea indica*)—alone show a struggle between habit and necessity, which results in a compromise that is as little satisfactory as such things generally are. The result is that they present a most dishevelled and dissipated look, with about half their withering old leaves still on the branches, which have as partially pushed out fresh growth and young leaves.

Once in the gardens, so brilliant with wreaths of the orange *Bignonia venusta*, gorgeous with wonderful Bougainvilleas of all shades, from the most splendid Indian red, through magenta-crimsons, purples, and mauves, to what may be called white, and all manner of tropical fruits, such as Bananas, Mangoes, Custard Apples, Guavas, and others, which are beautiful in foliage and fruit, nobody can fail to see how wonderful

this climate must be, where the sun does not scorch the blossoms, and where the soft air does not wither the tenderest growth. Soil, they say here, is the cause of the great depth and variety in the colouring of the Bougainvilleas, and I have been shown branches on the beautiful Indian red variety which sported to the most brilliant magenta-crimson, in consequence of fresh soil having been added, which has the appearance of being rich in oxides, if red colour be any test; but sunshine and breeze must also be important factors in the case, or such intense colours could hardly exist. Surely it must be an oversight not to plant *Bignonia venusta* at Nice or Cannes, where so many *Bignonia*s thrive well and flower more or less during the winter, and it is certainly a matter of surprise that so beautiful a flower as *B. Cherere* or *B. Tweediana* is equally unknown here. *Tecoma jasminoides*, *Bignonia radicans*, *Solanum jasminoides*, *Heliotropes*, *Cassia fistulosa*, and the handsome *C. corymbosa* are now in great beauty. Roses are not remarkable, save for their quantity, as they are not cultivated with any care; but one old Noisette Rose named Adam, in habit and scent resembling *Lamarque*, but with blooms shading to bright rose, is worth mention, if only to ask, why do we not grow it in England? A huge *Crinum* with giant umbels of red-purple-backed flowers, which open nearly white inside, is bold and handsome; and the big bushes of *Iresine Herbsta*, covered with feathery panicles of bloom like a white *Celosia*, are extremely graceful and pretty—a pleasant surprise to those who only have seen it in a ribbon border. Coral trees and an orange *Combretum* are unusual to European eyes, especially when associated with Dragon trees, *Pandanus* or Screw Pine, and the rich red-brown bushes of *Dracena ferrea* and *D. terminalis*. Almost every garden has a fine tree of *Strelitzia angusta*, whose large creamy white, blue-lipped flowers with bronzy sheaths are handsome, if not so brilliant as the well-known *S. Regina* that grows underneath. Sugar-canes, Palms, and acres of Bananas, with terraced Vines and Sweet Potatoes, make up the common round of every day vegetation here, replacing the Olives, Orange trees, and Rose fields of the Riviera; and *Ficus indica* and *Bella Sombra*s (*Phytolacca dioica*) make the most suitable boulevard trees. Near Funchal the climate is too dry for the Ferns that are said to be so beautiful on the damp north side, but the Hare-foot Fern is very common on the stone walls when over 1000 feet above the sea, resembling at a distance our English Parsley Fern on a giant scale, as the rhizomes are generally hidden among the stones. It is not my object to-day to do more than mention the fine scenery inland for which Madeira is as famous as for its climate, but rather to show that there is much to see and learn, which will more than repay any garden lover who does not object to a four days' voyage, when he will surely find flowers and warmth to greet him on landing here. E. H. W.

M. Louise, Neapolitan, and Comte Brazza Violets.—These three varieties of Violets are at the present moment laden with fine blooms. It appears to me that it does not matter what the weather may be—mild, severe, sunny, or sunless (the kind of weather we have had since December 6)—if the plants get proper attention through the previous summer, they are sure to repay it by a prodigious harvest of bloom from October to May. *Marie Louise* is a grand acquisition, especially in autumn and early winter, but it has in no way diminished my love for the Neapolitan, which is now, and has been for the last month, studded with flowers. An excellent judge of Violets always impresses upon me the fact that this variety is the sweetest, and has the most powerful odour of any of the Violets. *Comte Brazza* is very robust, and extremely floriferous, the plants at the

present being white with flowers. Like the Neapolitan, it is not so early to flower as *Marie Louise*, but once it begins there is literally no end to the amount of produce. It is sometimes recommended to cultivate the plants during summer in open sunshine, as then they make less foliage than they otherwise would do. That is a practice that I dare not venture on here, where our subsoil is sand—red spider would quickly make its appearance—but probably it answers, and I know it will do where the subsoil is clayey loam, and more retentive of moisture than sand. My best plants are always grown on north borders; the foundations of the wall seem to keep more moisture in the border during hot weather than is found in the open; and, with the exception of the rows nearest the wall, the plants get plenty of sunshine.—Wm. ALLAN, *Ganton Park.*

* * * The flowers sent were exceptionally fine—bright and beautiful to look at under a dull London atmosphere.—E.P.

ORCHIDS.

W. H. GOWER.

BURLINGTONIAS.

THESE are small-growing plants, natives of Brazil and other warm parts of South America. They enjoy an abundance of heat and moisture, and should be rested during the winter months by lowering the temperature, but not by drying them off, for if subjected to this process they recover with difficulty. *Burlingtonias* succeed best in hanging baskets or on blocks, but they dislike having their roots much covered. They require a moister air than that which the *Cattleya* house affords at some seasons, and therefore we have grown them in the East Indian house. All the known kinds are worth a place in our stoves, but the following are the best, viz., *B. fragrans*.—This is a tufted plant with small pseudo-bulbs and deep green leaves; the spike, which is erect, bears from six to eight large flowers, which are produced in April and May, and are pure white, except the centre of the lip, which is stained with yellow. They are deliciously fragrant, yielding a perfume resembling that of the Hawthorn. *B. candida*.—This is another plant of tufted habit. It produces somewhat larger pseudo-bulbs than the last and broader foliage. The spike, which is drooping, bears from three to six large snow-white flowers, which have several fleshy protuberances at the base, where they are stained with yellow. It is also a spring bloomer. *B. Leeana* is a plant of somewhat recent introduction from the country about the Rio Negro. It produces its flowers during winter and early spring; in habit it resembles the species previously named, but it is more robust in all its parts, and the pendulous spikes bear from five to ten flowers, the sepals and petals of which are creamy white, suffused with a tinge of rosy purple, and streaked along the centre with a narrow line of yellow. The lip is also creamy white, dotted and spotted with rosy purple, and ornamented with a yellow crest. *B. decora* belongs to a different section; in habit it is somewhat straggling, and should be grown upon a large block of wood, to which it will soon become firmly attached by its roots; the stems, which between the pseudo-bulbs are several inches in length, produce roots along their undersides. The spikes, which are erect, bear numerous flowers, the sepals and petals of which are convergent, white, blotched and streaked with deep rosy pink. The lip is large and white, and deeply lobed in front. It is a winter-blooming plant.

White *Cattleya Trianae*.—We hear that in several Orchid collections about London this chastely beautiful and much-coveted Orchid is in bloom. One of the largest specimens of it in this

country is now in flower in Mr. R. J. Measures' collection, Cambridge Lodge, Camberwell. This plant carried the other day no fewer than sixteen spathes, on all of which the flowers were expanded. They are snow-white with not a trace of colour in them except a dash of pale yellow in the inside of the lip. Mr. Measures' rich collection of Cattleyas will shortly produce a great show of bloom, plants of such sorts as *C. Triane* and *Percivaliana* being well furnished with flower-sheaths.

Long-spiked *Cœlogyne cristata*.—Mr. Tanner has now among his Orchids at Camden Wood, Chislehurst, some exceptionally fine *Cœlogyne*s. On one plant there are two spikes, one bearing no fewer than ten flowers, the others nine. We have not heard of so many flowers on a spike before. These spikes have been produced in a curious way, for instead of springing from the base of the last fully developed pseudo-bulb, they are produced from the top of small bulbs about the size of Hazel nuts, made after the normal bulbs were fully grown.

***Lycaste plana*.**—It is not often that one meets with this handsome Bolivian Orchid in bloom. Mr. Dorman, however, has it in that condition in his garden at Sydenham, in company with *L. Lawrenceana* and no fewer than four plants of the rare *L. Skinneri alba*. *L. plana* has flowers nearly as large as those of *L. Skinneri*, a species which it resembles in growth. The broad sepals are of a pleasing rosy red colour, and this, in contrast with the white inner petals which are adorned with erimson blotches, makes a pretty flower. In some varieties the lip is white, but usually it is spotted. It always flowers in winter and generally about this season, hence its value.

***Odontoglossum ramosissimum*.**—Ordinarily this is not a showy Orchid, but the best forms of it are extremely pretty and very different from the type. Mr. Dorman has a variety in bloom, at The Firs, Sydenham, which is one of the best we have seen. The flowers are spotted all over with violet-purple on a white ground, and not flushed with pink, as is usually the case. In habit of growth it resembles *O. cirrhosum*, the flower-spikes being tall, much branched, and bear numberless flowers having narrow wavy-edged sepals and petals. As it flowers during winter it is desirable. The *Odontoglossum* collection altogether is just now interesting. Of *O. Rossi majus* there are endless varieties in bloom, and also of *O. erispum*. Among others are *O. Andersonianum*, both the yellow and white forms; also *O. Cervantesi* and its superb variety *decorum*, whose flowers are larger than those of the original, and heavily spotted and barred with deep rose-purple.

***Oncidium tigrinum*.**—This is a very useful species during the late autumn months; its long spikes of primrose coloured flowers have a pleasant perfume resembling that of Violets. Now is its resting period, and therefore it should have a rather dry atmosphere, and a temperature of 45° to 50° suits it admirably. It should be placed quite close to the glass roof, and, as a rule, it needs no water until it shows signs of growth. With it are placed *Lælia majalis*, *L. autumnalis*, and the brighter coloured form *L. a. atro-rubens*. We flower *L. majalis* well annually by growing it in a light, warm position in the summer, and in a light, cool, and dry place in winter. We give the plants, as a rule, no water during the winter months.—J. D.

***Cypripedium caudatum*.**—Of this singular and well-known species large plants in good health have always been, and probably always will be, very valuable. I have grown it for many years, but my plants of it have not, as a rule, been so vigorous as I should have liked. We tried them in the cool house, but were not satisfied with the result. They were subsequently placed in a cool, rather shady part of the Cattleya house, where they did better; but with us the older leaves have a tendency to die back, making the plants look unsightly. Some time during the past season a very well grown specimen was exhibited by Sir Trevor Lawrence, and attached to it was a label stating that the plant in question had been grown

in the cool house for two years. Mr. Houghton, at Walthamstow, grows his plants in the warmest house, along with *Phalanopsis*s, *Cypripedium Spicerianum*, and other moisture and heat-loving Orchids, and they seem to do well. He had some plants, part of a recent importation, that seemed to be doing better than ours from the same source. This seems conclusive that an East Indian house answers best for this species.—J. D. G.

ORCHID CULTURE.

"W." speaks (p. 41) of Orchids not being ornamental. I admit there is not much beauty in many of the deciduous kinds when in a state of rest, but many varieties hold their own as regards variegation of an ornamental kind with what are termed fine-foliaged plants, and many others not variegated have a pretty and graceful habit of growth. I am not surprised that the grower alluded to by "W." should have given up his Orchids in disgust, when, to use "W.'s" own words, "he had plants which never flowered from the day they came—several years—many that flowered but sparingly, and only a few that flowered fairly well." In this case was there no blame attached to the grower? I was once asked by a gentleman to go and see his Orchids which he had decided to get rid of. I found them in a plant stove, cool and stove varieties receiving the same treatment—*Odontoglossum*s and *Cattleya*s, *Lycastes* and *Angraecum*s, *Oncidium*s and *Cymbidium*s side by side. I recommended that he should not give them up, but treat them according to their several requirements. My advice was taken, and now, although for want of space he has only a small collection, it would be difficult to find a more enthusiastic admirer of Orchids than he now is, or plants in a more thriving condition. "W." implies that Orchids are going out of fashion. If such is the case, I am at a loss to understand what becomes of the enormous consignments that continually reach this country. Orchids, as a rule, are not more expensive to cultivate than a collection of flowering and fine-foliaged plants. "W." admits there are a few varieties worth growing, but limits their number to ten, a number, which I think, might be a little extended. I should like to know which are the ten "W." would recommend. For supplying cut blooms during winter and late in autumn, Orchids are invaluable, both for freedom of flowering and beauty of bloom. Under judicious treatment flowers may be had in abundance, say, from the end of November till March, which, as a rule, are dull months. Here we have *Lælia*s in great variety; amongst them may be named *aneeps*, *autumnalis*, and *albida*; also *Lycastes*, *Odontoglossum*s in many varieties, *Cœlogyne*s, *Cattleya*s, *Dendrobium*s, *Phalanopsis*s, *Oncidium*s, *Angraecum*s, and many others. One other item may be mentioned in favour of Orchids, and that is, that really good varieties, given good cultivation, are always increasing in value, so that if the owner of such plants be at any time desirous of parting with them, he may rest assured of getting not only the money originally paid for them back, but in addition a good percentage on his outlay.—G. H.

— Here Orchid blooms, as well as those of Roses, have to be forthcoming all through the year, and in quantity. The East Indian house has for the last six or seven weeks been gay with such Orchids as *Angraecum sesquipedale* and the beautiful *A. Ellisii*, both of which are fragrant. We have also *Phalanopsis Sehilleriana*, with upwards of forty flowers on it, and even at this dull season they make a grand display. The rare and beautiful *P. Stuartiana* is also unfolding its blooms, and on *P. amabilis* there are thirteen flowers, not one of which is as yet spotted, as is too often the case with this particular species; it has been in flower for upwards of six weeks, and still retains its beauty. I feel confident that if only a few of these plants were disposed of at any of the auction rooms, they would realise more than treble what the whole collection cost three years ago. Surely "W." must confess, therefore, that here at least

Orchid culture pays. In the same house, too, are *Calanthes*, *Lady's Slippers*, *Saccolabium*s, and others intermixed with *Euphorbia jacquiniiflora*, *Poinsettias*, *Justicias*, and other stove plants, and the effect of the whole may be more easily imagined than described. Now, if we gave up the cultivation of Orchids and wholly depended on ordinary stove plants, we should never produce an effect at this time of year such as we do now. In order to convince "W." that Roses as well as Orchids are cultivated here on an extensive scale, I may state that the number of blooms cut from a Rose house 50 feet by 18 feet was above 2000 between October 21, 1885, and April 30, 1886.—A. J.

***Oncidium Marshallianum*.**—Amongst yellow-flowered species this is my favourite, but I must confess that, until the present season, I had not quite mastered its culture. It used to be grown suspended near the roof in the cool end of the Cattleya house, but the plants never seemed to grow there with very great vigour, and the bulbs either did not increase in size, or grew beautifully less. They have for twelve months nearly been grown in the cool house, and since the first month in which they have been placed there the increase in vigour has been steady and continuous. They prefer a light position, and basket rather than pot culture.—D.

***Aerides odoratum*.**—Amidst such a plethora of new orchidaceous plants this old-fashioned, sweet scented species is becoming neglected. That should not be so, however, for it belongs to a popular genus that can be maintained in good condition for half a century at least under good cultivation in an ordinary plant stove. It does not require a high temperature, and grows with less care bestowed upon it than almost any other stove plant with which I am acquainted. I have grown it in pots without any renewal of potting soil for three years, and the pots outside and inside have become quite interlaced with roots. The variety *purpurascens* has longer spikes than those of *odoratum*, and the flowers are more richly coloured. It was grown in the Royal Gardens at Kew so long ago as the year 1800, plants of it having been introduced by Sir Joseph Banks from China. Both kinds may be grown in any ordinary plant stove in which there is a winter temperature of from 50° to 55°.—D. S.

***Lycaste Skinneri* at Higham Hill.**—Since the Orchid conference was held some eighteen months ago at South Kensington, the question of applying manurial agents of some kind to Orchids has been before the public. Mr. Borwick, the owner of the collection at Higham Hill, has persistently advocated the use of fish manure for Orchids. Nearly, if not quite, the whole of the plants in this collection have been treated to fish potash manure in the shape of powder dusted amongst the potting material, or applied in the form of a pinch of the powder thrown into the water with which the plants are watered. All the Orchids thus treated are in a thriving condition, but the collection of *Lycaste Skinneri*, comprising about half a houseful, is as well grown as it is possible for such plants to be. The most remarkable evidence of good culture is to be found in the two years' growth of quite small plants. Bulbs not much larger than Windsor Beans will form a bulb four times that size in the first season, and this larger bulb will produce another the next season quadrupled in size. The lovely white variety grows quite as freely as the others. There are at present numbers of very beautiful varieties in flower, and these bear some relation to the quality of the plants, the flowers being clean, of large size, and of considerable substance. The potting material used is in all cases of the simplest description; the best fibrous peat is used for *Cattleya*s, *Lælia*s, &c., and the finer particles passed through a sieve are used for the *Lycastes*, a portion of loam and leaf-mould being used with them; in some cases loam and leaf-mould only are employed, and the plants succeed equally well. Many good Orchid growers fail to cultivate this handsome species of *Lycaste* well, while with others it succeeds well for a time,

but subsequently declines in vigour. Some grow their plants in the coolest house, and others succeed equally well with them under Cattleya house treatment. I have plants now purchased twenty-three years ago which are quite as healthy as others obtained four or five years ago. We only grow a dozen plants, and in that number we had two double-flowered peduncles this year. Mr. Gilks, the gardener at Higham Hill, told me that they frequently had two flowers on one stem there, but that they cut one off in order to allow perfect development in the case of the other. From personal experience I can assert that the use of leaf-mould with peat in Lycopodium-culture gives greater vigour to the plants than they otherwise would have. I grow the whole of our plants in the Cattleya house, as they grow with greater vigour there than in the more shady and cooler atmosphere of the *Odontoglossum* house.—J. DOUGLAS.

Phaius grandifolius.—In my opinion the remarks made by "W." (p. 41) apply to many kinds of Orchids, but there are others which can undoubtedly be grown as profitably as other flowers, and amongst these *Phaius grandifolius* deserves a place. It is one of the easiest managed and most floriferous of Orchids. It may be grown like any ordinary stove plant in summer, and it never fails to throw up its flower-spikes most freely at this season. Our best plant last year produced fifteen spikes. They were about 1 foot high each; the blossoms began to open on them at the beginning of March, and they were not over until May. The single blooms, if taken off and wired, are very useful. I do not know any ordinary flowering plant which would stand so much knocking about in church or mansion without being injured or destroyed as this does. It likes rough material in which to root, abundance of water, and plenty of light.—CAMBRIAN.

Phalænopsis amabilis.—Of this I send you a specimen, in order to show how we grow it at Henham. I have forwarded single flowers of this *Phalænopsis* before, but by the enclosed cut spike you will have a better opportunity of judging what a beautiful Orchid it is. We have similar spikes every year, but have not seen a better than that which I now send you on this variety.—GEO. EDEN, *Henham Hall, Suffolk*.

* * The spike received is truly beautiful, being upwards of 18 inches in length and bearing thirteen snow-white flowers, unusually broad in the sepals and petals, and measuring nearly 4 inches in diameter.—ED.

SHORT NOTES.—ORCHIDS.

Zygopetalum Mackayi majus.—This is a most useful winter-flowering Orchid. The flowers remind one of those of a lovely Iris, and they are very fragrant, but perhaps one of its most meritorious points is the grand way in which it submits to being confined to a room when in blossom. A plant here which was attractively in flower on December 1 was placed in a room on that date, and at the present time, January 24, it is there still as bright, fresh, and fragrant as ever. Could anything in the form of a flowering plant do better than this? I think not.—J. MERR.

Calanthes.—Some of the finest of these I have seen this winter were grown at Hendre. The varieties were *C. vestata* and *C. Veitchi*. The majority of the spikes were about 4 feet in length, and a yard of this length was covered with fully opened blooms, remarkable for the brightness of their colour. The bulbs are kept quite dry when developing their blossoms, and this is undoubtedly the best of all ways in which to treat them.—J. M.

Cattleya Trianae alba.—We have received from Mr. W. Gibbs a beautiful form of this rare Cattleya, the flowers of which measure fully 6 inches in diameter. The sepals are narrow, but the petals are nearly 2 inches broad, and undulated at the edges. The lip is also pure white, with a faint stain of lemon colour towards the base, the front being deeply crenate. The same form also comes from Mr. Horstman, of the Marks Tey Nursery.

Cattleya Percivaliana.—Flowers of a very fine form of this labiate type of Cattleya came to us from Mr. Osborne, Wilton House, Southampton. This section is not generally notable for size, but the flowers before us measure, nevertheless, nearly 5 inches across, and they are exceedingly fine both in colour and form; the petals are much broader than the sepals, and deep rosy bluish suffused with violet. The lip is prettily fringed on the edge, and bordered with a deeper shade of the same hue, passing into purplish crimson; centre rich velvety maroon, basal portion blotched and raged with deep orange. This is one of the finest varieties of this useful winter-flowering Cattleya which has come under our notice.

Odontoglossum Rossi majus.—With this I send you six varieties of *O. Rossi*, which we think are very distinct, viz., *Humeanum*, *asperum*, *rubescens*, and a supposed cross between *Rossi* and *Cervantesi*. With these are associated two other fine unnamed varieties: also flowers of the distinct *Lycopodium* *Barringtonia grandiflora* and a very fine variety of *Odontoglossum odoratum*, likewise *Cattleya Trianae* (Measures' variety), cut from a plant with thirteen leading growths and nine flower-sheaths. The flowers sent have been open more than a fortnight. Other *Cattleyas* blooming here are *C. Trianae Dodsoni*, a very large-flowered and handsome variety; *C. chocoensis amena*, also sent, you will observe the fog has completely crippled. It is an elegant and delicate flower, the brilliant colour on front of the otherwise pale lip rendering it very attractive. The *Laelia anceps* sent we recognise as the best variety. This spike opened at Mr. Measures' county house, the fog having cut off all our *anceps* in London this season.—H. SIMPKINS, *Cambridge Lodge, Camberwell*.

* * The forms of *Odontoglossum Rossi* sent herewith are very fine indeed; *O. Humeanum* and *O. asperum* are, however, separated from *Rossi* by Prof. Reichenbach, who considers them natural hybrids—the former between *O. cordatum* and *O. Rossi*, and the latter between *O. Rossi* and *O. maculatum*. The last has much the appearance of a yellow-flowered form of *O. Rossi*. The *Laelia anceps* is a large, bright-coloured form, and the *Cattleyas* are charming, confuting the assertion that Orchids are not ornamental, even during winter.—ED.

NOTES OF THE WEEK.

Helleborus niger major.—Our Devonshire variety of this is now finely in bloom, and a very handsome Christmas Rose it is. The flowers have long foot-stalks, a great advantage when they are used in a cut state.—ROBERT VEITCH & SON, *Exeter*.
* * Foliage and blooms both fine, and the foot-stalks, being so stout, hold the flowers erect.—ED.

Christmas Roses.—Herewith I send you flowers of a pretty form of what I presume to be *Helleborus antiquorum*. It is always the first to open of this section, and the colouring is distinct and attractive. F. MOORE, *Royal Botanic Gardens, Glasnevin*.

* * A handsome Christmas Rose of a dull reddish plum colour outside, but paler within, and most welcome at this season of the year.—ED.

The white winter Heath (*Erica hyemalis alba*).—This new white form of the old and well-known winter Heath is a welcome addition to winter-flowering greenhouse plants. It is the exact counterpart of the type in habit of growth and floriferousness, differing only from it in colour, and when better known it cannot fail to become extremely popular. We saw it recently finely in flower in the nurseries of Mr. Kinghorn, at Richmond.

Acrotiche divaricata is the name of a pretty little plant at Kew that seems worth attention as a winter greenhouse shrub. It has the appearance of a small *Epacris*; the branches are very slender, and every twig is terminated by a cluster of snow-white flowers. The plant is a profuse bloomer, and as neat as a Heath in growth. Its flowers would be found very useful for making up small button-hole bouquets. It may be seen among the Australian plants in the temperate house.

The late Marshall P. Wilder.—At a meeting of the Massachusetts Horticultural Society held the other day, it was stated, concerning Col. Wilder, that a fund established by the provisions of his will, by which medals are annually to be given for the encouragement of the cultivation of certain fruits, would for ever be associated with his name, and would be the means of perpetuating his memory.

Royal Botanic Society.—Arrangements for 1887.—Exhibitions of spring flowers, Wednesdays, March 23 and April 20; summer exhibitions of plants, flowers, and fruit, Wednesdays, May 18 and

June 15; evening fête and exhibition, probable date, July 6; special exhibition of American plants, by Mr. Anthony Waterer, Knap Hill, Surrey, daily during June; promenades, Wednesdays in May, June and July at 3.30 p.m.

Acacia longifolia.—This is one of the very best of the *Acacias* for growing as small plants for the greenhouse, and as it is one of the earliest to bloom it is the more valuable. Some well-grown pot plants in the greenhouse at Kew make a very bright show, the clear sulphur-yellow of the flowers being different from that of others. They are produced in dense round spikes about as thick as a pencil, and some 2 inches in length, and these spikes wreath each of the slender branches. It is a far finer plant than the common *A. platyptera*, also in flower now, which, though singular in growth and floriferous, is not of such a good telling colour.

The Silver Wattle tree (*Acacia dealbata*) is again the chief attraction of the great temperate house at Kew. The fine tree of it, which reaches the roof, will be presently quite a golden cloud of blossoms, which, with the silvery foliage and white stem and branches, have a charming effect. This tree has for many years been the feature of the house for several weeks from the end of January, and it seems to have reached its full growth, and it is only when such grand specimens as this are seen that one can form an idea of the glow of colour these *Acacias* make in the Australian bush, and one can scarcely judge of the grandeur of this Kew tree from seeing the Silver Wattle as a pot plant.

The white Freesia.—A lovelier or more fragrant plant than this does not exist, and its blossoms at this dull season afford the greatest treat in the greenhouse that one can have. But it is not generally known that *Freesias* may be forced into bloom so early or so easily. A few weeks only elapse from the potting of the bulbs till the flowering time, and if good sound bulbs only are potted, and these not subjected to a great heat, a good crop of bloom will be the result. The pure white variety known as *F. refracta alba* is the sort to choose, the flowers of the others being of a yellowish tint, while those of *alba* are pure white, and deliciously scented like Violets. A group of white *Freesias* in the greenhouse at Kew quite scents the house.

The Rose Mallow (*Hibiscus rosa sinensis*).—It is much to be regretted that this extremely showy, free flowering, and easily-grown plant is so little cultivated as it is in private gardens. It is an excellent subject for covering back walls in lean-to stoves, and by a judicious use of the knife can be readily formed into a handsome specimen in a pot; there is no lack of variety in the colour of the flowers both single and double. A large single scarlet variety, named *fulgidus*, having a crimson blotch at the base of each petal, we saw recently covering the back wall of a stove at Beddington House, where it was very effective; the large, rich, shining, green leaves quite hid the wall, and formed a charming background for the brilliant blossoms.

Iris reticulata.—Roots of this I potted up in August, and plunged them in a cold frame till December; then I placed them on a shelf, near the glass, in an early Rose house, in which the minimum temperature was 45°. With this small amount of forcing we were able to have them in flower along with the earliest batches of *Lily of the Valley*. When one takes into consideration the heat required in order to have *Valley Lilies* by Christmas and the new year—certainly not less than 80° or 90°—it is surely a great recommendation to this handsome little Iris, with its Primrose-like fragrance, that with so little trouble and attention it may be had in flower in the depth of winter.—WM. ALLAN, *Ganton Park*.

* * With this came lovely flowers—beautiful even as those of an Orchid, rich deep violet in colour, set off with bright yellow markings on the blade; their fragrance, too, is delightful; doubtless the ease with which this Iris forces arises from the fact that it blooms naturally, in ordinary seasons, in the open air, in the end of January and February.—ED.

The Nepaul Barberry (*Berberis nepalensis*), a common plant in open air gardens, is now a fine object in the temperate house at Kew, where there is a plant

10 feet or 12 feet high in bloom. Each of the tall stems is terminated by a dense cluster of lemon-yellow flower-spikes, and these, with the long, handsome foliage and chalky white stems, are highly attractive. It is only when planted in a large conservatory or against a warm wall that the full beauty of this noble Himalayan Barberry can be seen, for it rarely flowers when planted in the open. It is one of the handsomest shrubs one could choose for planting out in a large, cool conservatory border, for, being an Evergreen, it is a handsome object all the year round.

GARDEN IN THE HOUSE.

Spiræa japonica.—This is of such exceptional merit indoors as to be worthy of a prominent place, and it is of very easy culture. Few flowering plants indeed have such an elegant appearance, the plume-like masses of bloom, so pure in colour, being set off to the best advantage by the fresh green, much-divided, elegantly-disposed foliage. As regards habit, this *Spiræa* is the ideal of what a pot plant should be, and it is not to be wondered at that it should be in such great demand for indoor ornamentation. Many thousands of it are annually disposed of in Covent Garden Market, and it is equally in favour in other countries. The important point is to obtain well-grown roots, for small weakly pieces yield but a faint idea of the beauty of this *Spiræa*. These should be obtained at the close of autumn when growth has come to an end, and be potted at once in their blooming pots, in free but rich soil, such as loam with a good addition of decomposed manure. From the beginning of November till the middle of March a cool room is the best place. After the last-mentioned date they will do very well in a living room, and will, of course, come into bloom earlier, but if allowed to come on in a cool temperature, the flowers will be much finer. As this *Spiræa* is a coarse-rooted plant, the pots become well filled with fibres by the time the spikes are thrown up; therefore, they require an abundance of water during that time onwards, and some weak liquid manure at frequent intervals. It is absolutely necessary that the growth be made in the open air; therefore, the last week in May plants which have bloomed in the dwelling should be turned out. Do not neglect to water them, and, if you have a garden, you cannot do better than plant them out in rich soil for the summer. As they will be too large for the same pots the following year, it is best to cut the clumps in two when setting them out. If they are to be kept in pots they will need dividing and repotting in rich soil, and in this way *Spiræa japonica* may be successfully grown where there is no convenience for planting out. *S. palmata* resembles its congener in manner of growth; it is not quite such a graceful plant, but the flowers are of a fine rose colour, and it is well worthy of careful culture. The treatment required is identical with that described for *S. japonica*.—J. C.

Deutzia gracilis.—When in good bloom this is one of the most pleasing plants in cultivation, the numerous pure white flowers contrasting admirably with the delicate green foliage. Although by nature a hardy shrub, and therefore of easy culture, it does not seem to be so well grown as one would think it ought to be—a fact attributable to the want of liberal culture after the blooming season. I would advise window gardeners to grow this little shrub in a cool room; it blooms much better when it comes along very gradually, and in the confined atmosphere of a living room the flowers are apt to come very small and deformed. Like *Spiræa japonica*, the *Deutzia* enjoys a free root run in good soil throughout the growing time, and this is the way florists and market growers treat their plants. At the same time good results are obtainable when the plants are ripe in the pots, but they require strict attention in the matter of water and feeding when making their growth. *Deutzias* often suffer much when they are turned out of doors after blooming, and cold nights and biting winds cripple the growths,

which are more tender than those of any flowering shrub that I am acquainted with; and therefore they should remain under cover, and where they get plenty of air until quite the latter end of May. Those who possess a cold frame will have no difficulty in giving their plants the treatment they need after blooming; but when this accommodation fails, select some sheltered, rather shady position, allowing them to remain there for a week or two, and then placing them in full sun. Another equally important point is not allowing them to want for water and food, as such neglect induces a crippled condition, which it takes a month or two of liberal culture to remove; I may add that unless these little details are observed, there will be but little use in attempting to grow this *Deutzia*.—BYELEFT.

CAMELLIA CULTURE.

BUD-DROPPING.—It is not unusual for *Camellias* which at the end of the autumn are full of buds to cast the majority of them during the winter. Bud-dropping, in the case of *Camellias*, is undoubtedly due to an insufficiently active flow of sap at a critical moment. Just at the time when the first flowers begin to open, the great strain on the resources of the plant commences, and it stands to reason that if only sufficient food for a dozen buds is drawn up, and if there are more than that number on a plant, some of them must suffer. This is the case with all flowering plants, but they show it in the shape of small or deformed blooms; whereas the *Camellia* gets rid of the buds that it cannot nourish. It is a singular fact that weakly *Camellias* are apt to set a larger number of buds than those in robust health. The buds are, however, not large, and lack substance. I have noticed this peculiarity in the case of many kinds, notably such free blooming varieties as the red, double white, Lady Hume's Blush, and Donekelaari. When a not over-strong plant carries half a dozen, or more, buds on a shoot, it is a great chance if any of them comes to perfection. The best way in such cases is to give the plant a complete rest by picking off the buds for a year or two. This, in combination with good cultural care, will bring it into a healthy, floriferous condition in a couple of seasons. There are not many, however, prepared to make so great a sacrifice, and unless a plant is in a very bad state indeed, disbudding will suffice. Not more than one bud to a shoot should be left, and the thinning should be done as soon as the buds are formed. By retaining all the buds none of them will become good, well-formed blooms whilst they remain on long enough to keep the vital forces of the plant at a low ebb.

There are some kinds, such as *Jacksoni* and *Mathotiana alba*, that produce buds sparingly, and in a general way in their case there is but little margin for thinning, but the generality of *Camellias* are the better for being examined as soon as they are housed, leaving only as many buds as the strength of the plants will allow them to develop properly. This will alone in many cases do away with bud dropping, and would maintain the plants in a healthy state. Overcropping a *Camellia* lowers its vitality for some years. The great point is to know how many flowers a plant is able to expand without distress, and to leave that number only. Although bud-dropping does not as a rule occur before winter is well on its way, the injury is often done at a much earlier period. A dangerous time is when the plants are brought in from the open air. Unless care is taken to give them plenty of air for a time the change is apt to partially arrest the flow of sap, and then good bye to a satisfactory show of bloom. Another fertile source of mischief is fire heat in winter. Dry heat is what *Camellias* cannot bear. A gentle warmth of from 50° to 55° will be rather beneficial to them than otherwise, but give them 10° or so more and you court disaster.

REPOTTING.—Opinions differ considerably as to the best time for repotting, some preferring autumn when growth is completed and before the

roots have ceased to be active, whilst many choose the late spring months for doing so. I should myself prefer the latter period, choosing the moment when young growths are beginning to push. This is the time when *Camellias* are always kept warmer and closer than usual in order to promote early growth, conditions which favour free root action. If discrimination is used as regards the amount of fresh soil employed, the roots ought to take good possession of it by the autumn, so that when placed in the open air they are in a condition to bear heavy rains without suffering. If potted in autumn they ought to be taken under cover immediately, or many of the roots will decay. I cannot but think, however, that it is rather risky to repot *Camellias* when buds are on them. There is one thing about which all *Camellia* growers ought to be careful, and that is to avoid all semblance of overpotting. The health of thousands of good *Camellias* in this country has been permanently injured in this way. I do not know any flowering plant that can be retained in a floriferous condition for so long a time in a root-bound condition as the *Camellia*. One grower told me that he had not repotted his plants for seven or eight years, and stated that he did not intend to disturb them for another equally long period if they remained in the same healthy floriferous condition that they were then in. I myself have had plants in my charge that had not been repotted for ten years, and they looked remarkably well. They were, however, in tubs and very large pots. In the case of young plants it is, of course, desirable to bring them along as quickly as possible, and their roots should not be allowed to become too thickly matted. As to compost, either peat or loam alone will grow good *Camellias*, that is, if the right material can be obtained. I have always preferred about half of each with a dash of leaf soil, plenty of silver sand of the coarsest description, and a little charcoal, which, by the way, is about the best thing that can be used as drainage. Young plants should not be potted hard, but when they come into 8-inch pots they can scarcely be potted too firmly. Firm potting causes the roots to ramify and fill the upper portion of the compost better than when they can easily find their way to the bottom of the pot. This is one of the surest safeguards against the soil becoming soddened.

RENOVATING UNHEALTHY PLANTS.—Whatever may be the cause of ill-health in *Camellias*, the roots are sure to be deficient in quantity and activity, and before top-growth can again become satisfactory they must be brought into a healthy condition. The surest way of doing this is to put them for a time on a spare diet. As much of the old soil as possible should be got away; the plants should be replaced in clean, well-drained pots just sufficiently large to contain the roots, using fine, well-sanded peat. All pieces of decayed roots should be cut away with a sharp knife. With careful watering and suitable atmospheric conditions a certain amount of healthy growth will be made the following season. In a general way the fresh compost given will be enough for a year or two. When the pots get full of roots and a good amount of healthy foliage is made, they may be shifted again. After potting they should be placed in a close house and be well syringed twice a day in fine weather, keeping off hot sun. On no account should plants which are undergoing this process of restoration be allowed to flower. J. C. B.

QUESTIONS.

5543.—**Pear tree scale.** If any reader of THE GARDEN would kindly give the best means of freeing Pear trees in an orchard house from scale, I would feel obliged.—M. D.

5544.—**Sulphate of ammonia.** I have been told that this is a capital manure for Vines, Peaches, and pot plants generally. Will someone kindly say if that is so, and the strength at which it should be used?—P. S.

5545.—**Skating-rink.** I should be very grateful if any reader of THE GARDEN would give me a few practical hints for the best construction of a skating-rink. I can procure water through pipes for flooding the same when necessary.—V. T.

ROSE GARDEN.

T. W. GIRDLESTONE.

ROSE-COVERED PORCHES.

How is it that plants are often seen flourishing in cottage gardens with a luxuriance which seems unattainable in gardens where all conditions appear to be so much more favourable? The great masses of Hepaticas, for instance, in the cottagers' gardens in some of the western shires are unsurpassed, while the clumps (sometimes almost forests) of Madonna Lilies are the envy of passers-by, and the climbers by which the cottage is often half hidden seem to grow with more enjoyment than anywhere else. Perhaps the reason may not be further to seek than in the employment of materials well suited to the climate and conditions, for there is no doubt that common plants well grown are more decorative than half-starved specimens of more brilliant things, for whose proper cultivation the requisite means are not attainable; and a cottage porch smothered with Honeysuckles and some old-fashioned Rose is about as pleasant a sight as can be seen, in spite of the climbers being neither rare nor costly.

of striking specimens in cottage gardens will probably be found in the fact that, not being too numerous, each plant is tended and looked after with the greatest care; the precious and carefully collected road-scrapings, not having to be spread over too wide an area, are heaped round special favourites to provide at once food and protection, and thus is encouraged that luxuriance of growth which renders possible the Rose-covered porches of our Surrey cottages, whereby a pleasant feast of brightness is afforded to weary travellers passing by.

— It is remarkable how seldom the white Rose (double or garden variety of *Rosa alba*) is to be seen in any but cottage gardens, and the same may be said of its near relation the Maiden's Blush. Such good Roses, capable as they are of highly ornamental treatment and so individually charming, certainly deserve more general culture than they receive. The white Rose does equally well as a bush 5 feet to 6 feet high, or as a low climber. The cottage porch we engrave shows it in the latter form, trained to meet a Honeysuckle in the front, the training not overdone, but with that happy knack of supporting and guiding without apparently constraining, that

with Roses entirely unfitted for the purpose, or the employment of too many varieties. The number of available sorts is not large, and perhaps a dozen names would exhaust the list of first-rate kinds, but the employment of these or any twelve different Roses upon some half-a-dozen arches would effectually preclude the possibility of anything like a fine display. On the other hand, what could be more striking than such a series of arches, each arch densely wreathed with the Evergreen *Félicité Perpétuelle*, probably the best of all varieties for the purpose, with its rampant growth, its dark green persistent foliage, and its myriad pure white flowers, each one a perfect rosette. If numerous varieties are employed, the result is seldom satisfactory from a decorative point of view, because the different sorts will not flower at the same time; but this difficulty is obviated by using only one variety at a time, whereby the striking effect obtainable by having a number of arches of Roses simultaneously sheeted with bloom is ensured.

In case of the employment of several varieties on a series of arches, each arch, at any rate, should be covered with one Rose, and not have two different kinds planted beside its two pillars, so that at the flowering time each arch, at least, may be complete, rather than have one half blossoming while the other half is green or bare. Even if they can be induced to bloom at the same time, unless they are of the same class and habit, the effect of two different Roses mixed up together is generally somewhat incongruous and unpleasing.

In the selection of varieties the qualities to look for, in addition to the obvious essentials of rampant growth and profusion of bloom, are hardiness, pliability, persistence of foliage—which foliage should be handsome, but only of moderate size, as the very large-leaved Roses, when grown on arches, get their leaves so lacerated by the wind and soon look untidy—and comparative freedom from the more disfiguring of Rose pests, such as mildew, &c. In addition to *Félicité Perpétuelle*, which is unsurpassed as an arch Rose, there may also be mentioned as fulfilling the above conditions the Ayrshire splendens, whose white flowers, less regular in outline than those of the last-named, are relieved by a slight pink edge. These two varieties are the pick of their respective classes, but if a pink variety in the same section be desired, there is no fault to be found with the Hybrid *Laure Davoust*, whose charming pink flowers are produced in immense clusters, except that in the north it is not quite hardy enough to avoid some disfigurement in a severe winter, unless it be somewhat protected with Bracken, or such covering. In the southern counties, however, both this and the climbing *Aimée Vibert*, or *Aimée Vibert scandens*, as it is sometimes pelantically called, make good arch Roses, and the two are sufficiently near in character to make a good pair, the one pink and the other white, where several sorts are desired. But when it comes to the *Noisettes*, there are two varieties of which use should be made whenever possible, for if not perfectly hardy they are well worth the slight protection of Fern, which renders them so. The first of these is *Rêve d'Or*, an exceedingly vigorous Rose and the hardiest of its class—a Rose which could not be considered otherwise than a highly ornamental plant, even if it never flowered, for its young shoots are brilliant red, and the handsome foliage is rarely without some bright tint; but its character does not belie its name, and the wealth of golden and tawny blossoms displayed constitutes truly enough a vision of gold, and not a fleeting vision like an every-day dream either, for the flowering only ends when the frosts begin. The second variety is the now well-known and deservedly popular

Climbing Rose on porch of cottage in Surrey. Engraved for THE GARDEN from a photograph.

But the supposition that the denizens of cottage gardens are so fine because they are indigenous or exceptionally hardy plants is not sufficient to account for the handsome subjects there so often met with; the finest Catherine Mermet I ever saw was climbing on the chimney of a cottage by the roadside in Surrey, and in a similar position in another part of the same county I have seen blooms of *Gloire de Dijon* such as I have never seen elsewhere, even in celebrated Rose gardens. Everyone will doubtless recall Canon Reynolds Hole's description of the noble specimens upon the walls of a cottage of the glorious, but hardly-to-be-flowered *Noisette*, *Cloth of Gold*, which so rarely gets sun enough to ripen its shoots in this climate, and even more rarely succeeds in preserving them uninjured until the flowering time. I myself have experienced the pangs of jealousy when passing a house masked with a climbing *Devoniensis* in full bloom, the cultural attention to which consisted in its being occasionally gone over with a long handled bill-hook, such as is used in trimming hedges, "just to keep the shoots from rattlin' on the windows."

In spite of these seemingly anomalous instances, however, the real reason of the presence

best shows the beauty and natural growth of rambling plants.

ROSE ARCHES.

THE mode of decorating our gardens with arches of Roses carried over paths seems of late years to have gone very much out of fashion, although Roses so grown may be made to constitute a very attractive feature, a fact to which the engraving in last week's GARDEN abundantly testifies. It has been urged that Rose arches are always ineffective or inconvenient, and generally both; but if so the reason is probably to be found in a want of skill in the cultivator or constructor, or both. For there is no design that is safe from being made to appear ridiculous through its attempted execution in ill-chosen materials; a house built of bricks and stucco from designs intended to be carried out in stone would not be more grotesque than the gaunt iron arch one sometimes sees with a stunted Rose bush growing half way up each of its pillars. Such an arrangement certainly is ineffective, but then it is not a Rose arch. Where there has been a want of success in making Rose arches decorative, the failure may usually be attributed to one of two causes, either an attempt to furnish them

William Allen Richardson, not so rampant as Rêve d'Or, but quite sturdily vigorous enough for all practical purposes, and very nearly, if not quite, as hardy as the latter. At any rate numerous plants of William Allen Richardson of various forms passed unharmed through the trying winter of 1885-86 with only the slight protection of a few fronds of Bracken twisted among them, which all Teas and Noisettes deserve and are the better for in hard weather; and, as far as can be seen at present, the long spell of cold now coming (it is to be hoped) to an end, although the thermometer twice registered upwards of 25° of frost, has not inflicted appreciable injury on plants of this delightful Noisette, whose decorative value is enhanced by the fact that the bright orange colour of its flowers is unique among Roses, while the plant is almost evergreen and thoroughly autumnal.

Red Roses that are available for training over arches are few and far between, but the Hybrid Tea *Reine Marie Henriette* is a first-rate variety for the purpose, and, growing with immense vigour, produces its bright, clear red flowers in abundance throughout the season. The attractive semi-double red Hybrid Tea or Hybrid Noisette *Reine Olga de Wurtemberg*, which was figured in *THE GARDEN* early last year, would make an admirable arch Rose, but for the solitary objection that its magnificent foliage is liable soon to become "tattered and torn" by the action of the wind when this Rose-giant is grown anywhere away from a wall. But a lack of good hardy red climbing Roses is no reason for ignoring good hardy climbers that are ready to hand, even though they be not bright-coloured; and there are two single Roses which are both better worth growing to cover arches than all the Hybrid Perpetuals so often recommended put together. One is *Rosa Brunonis*, often called the Himalayan Brier, which makes incredibly long shoots, enough to furnish an arch in a single season, and of which the pretty bluish green foliage is almost hidden at the flowering time by the mass of snowy single blossoms; the other, last, but not least in value at any rate, is *Rosa polyantha*, a Japanese sub-species of *R. multiflora*, and one of the most attractive Roses in cultivation. It has all the recommendations enumerated above; it grows with the utmost luxuriance, and regularly becomes smothered with blossom. M. Jean Sisley, of Lyons, declares his belief that it is the hardiest Rose in existence; it may be easily trained in any direction; the foliage hangs on late, and though composed of many leaflets, the leaflet is not large, and the plant appears almost exempt from mildew; moreover, it will grow in any soil or situation, it roots as a cutting with the greatest readiness, and its white flowers, though individually small, are produced in such immense trusses as to be highly decorative, while their delicious fragrance scents the air for yards round a large plant in blossom. Under these circumstances, the only wonder is that this plant is not abundant in all gardens where Roses are appreciated; but the fact probably is, that too many gardeners still consider single flowers a reproach to a Rose, which no other merits can compensate.

There are many other Roses which are often included in lists of kinds said to be desirable as arch Roses, such as the Boursaults, which, however, cannot conscientiously be recommended on account of their dreary colouring. Again, the charming Rose which goes under the name of *Fortune's Yellow* is too tender to be grown in this country anywhere but against a wall—a position which it thoroughly deserves; and the same may be said of the *Banksias*. None of the Mosses are of real value for the purpose; *Lancei* is the only one of sufficient vigour, and that is too stiff and rigid to

be ornamental. One or two Hybrid Chinas, such as *Blairi No. 2*, may be employed, but all the Hybrid Perpetuals practically involve an outlay of time and trouble by no means repaid by the effect produced; while the few Gallicas, &c., that might possibly be available are such victims to mildew as to be hardly ever otherwise than an eyesore.

In arranging Rose arches it must, of course, be borne in mind that it is essential that things intended for use be eminently usable; and if arches are made across a path, care must be taken that they do not make such path inconvenient for traffic. Thus, the pillars of an arch should be at least 3 feet from each margin of the walk spanned, in order that the dresses of passers-by may be safe from the thorny shoots; and if the walk be 6 feet wide, this will give a base of 12 feet wide, for which a central height of 10 feet will be found to give an effective and practical arch. Where there is to be a series of arches, they should be at least 3 yards or 4 yards apart, and each arch should be composed entirely of iron, for if the uprights be made of wood they soon give way at the ground-line, especially when the plants trained upon them become vigorous and offer considerable resistance to the wind. The only objection to iron uprights is that from their smaller diameter they are less convenient to train plants to than wooden posts; but any difficulty arising from this may be obviated by fixing a few horizontal cross-bars on to the iron uprights, and to these the Rose shoots can be tied so as to avoid undue crowding in the earlier stages of growth. The best way of planting is to put in two trees of the same kind, one at the foot of each upright, and then by liberal culture to encourage the most vigorous growth possible; but if a variety is used which does not furnish well, there is no reason why two or three plants of it should not be planted at either pillar in order to get the arch more completely wreathed. Then, if varieties well adapted to the purpose, such as those above suggested, be employed, the shoots from the two sides will soon meet across the centre, and, interlacing, form a triumphal arch or series of arches of a most attractive kind.

PROPAGATING.

TREES AND SHRUBS.—Where different hardy trees and shrubs are propagated many of them are grafted on allied kinds, and in the case of some of these it is necessary to keep them under glass till a union has taken place. When stocks are required for this purpose they must be potted during winter, and plunged in the open ground till needed. No time should therefore now be lost in potting up any stocks not yet moved, and which are likely to be required. This more particularly applies to such trees and shrubs as the various Conifers, *Rhododendrons*, some Oaks, *Ivies* (as stocks for the tree varieties), *Privets*, which may be used as stocks not only for members of the same genus, but also for the allied species of *Osmanthus*, and for the deliciously scented *Olea fragrans*, which grows well treated in this way, but though grafted on a hardy shrub it will not withstand our winters out of doors. The common Spindle tree is by some largely used as a stock on which to graft the various variegated forms of the Japanese *Euonymus*, and, strange to say, the deciduous character of the stock does not in the least seem to affect that of the scion. In potting up stocks for grafting, all straggling branches should be shortened, and the height of the plant may, if necessary, be reduced. One thing to bear in mind is that space under glass even during summer is somewhat limited, so that in order to economise it the different stocks should be put in as small pots as possible consistent with the preservation of the roots. Small

pieces of Spurge Laurel (*Daphne Laureola*) may also be potted if likely to be required later in the season on which to graft the sweet-scented greenhouse kinds.

DRACENAS may now be propagated in quantity, as if struck thus early in the season they may be grown into good-sized specimens soon enough to become well coloured before winter. Where they have been employed indoors during winter there will be plenty of plants with just a few leaves on the top of a tall, naked stem. These are the very best for propagating purposes, as the tops can be cut off just below the leaves, or rather with stem sufficient to hold the cutting in position. Pots for their reception should be prepared by placing a few broken crocks in the bottom and filling up with a compost consisting principally of peat and sand in about equal parts, with just a little loam to give it body. When the cuttings are inserted they must be pressed down firmly, and as the leaves are heavy and often sway about, they are best secured in position by means of a small stick, as unless this is done the action of rooting is retarded. One point to bear in mind is, on no account to allow any soil to get about the base of the leaves, otherwise decay is apt to set in there. After the cuttings are in their pots a thorough watering must be given; they can then be plunged in a close propagating case in a bottom-heat of from 80° to 85°, when they will soon root. When the tops are disposed of the stems may be shaken out of their pots and cut into pieces of 3 inches or 4 inches in length. The thick fleshy roots may also be treated in the same manner, only in their case a length of a couple of inches will be quite sufficient. These stem cuttings should then be laid horizontally on a bed of Cocoa-nut fibre, and covered for about an inch with the same material. A space of an inch or more should be left between each row of stems or roots to allow room for the plants to grow when they make their appearance. If these cuttings are put in a close propagating case no water will be needed, for the condensed moisture and that contained in the fibre will be sufficient to maintain them in a fresh condition till growth takes place. In a short time young plants will be pushed up from every joint, and when they have made four or five leaves they will be quite fit to be removed from the parent stem. On moving them, nearly all the young plants will be found to have pushed out roots; all that is necessary then is to pot them, and, after keeping them close for a few days in order to allow the roots to recover from the check sustained, they may then be inured to the ordinary treatment of a stove. After the shoots have all been removed the stems that are still sound may be laid in again if any more plants are needed, but the second crop will be by no means equal to the first. Some prefer to lay the stems in well-drained pots or pans of sandy peat, treatment which is perfectly successful, but longer time is needed than when laid in fibre, though where numbers of different sorts are grown they are less liable to become in any way mixed if a pot or pan be kept for each sort. By some, too, the large tops are simply struck in the fibre; this they do readily enough, but the roots there formed are so brittle that the greatest care is needed in potting them. In this respect those struck in small pots have the advantage, as they can be shifted into larger ones without injury. Some *Dracenas* cannot be increased by means of stem-cuttings, and in their case a slower mode of procedure is rendered necessary. Among the best known of these are *Goldiana*, *gracilis*, and *eugesta*. In their case the top must be cut off, and treated in the same way as the first-mentioned kinds; but instead of turning the naked stem out of the pot, it must still be kept there, when another head will be produced to take the place of the one removed, and when large enough it is then available for a cutting. By this means a considerable number can, in time, be produced from a single plant; but, of course, the rate of increase is much slower than in the case of those whose stems break freely into growth. Where it is especially desired to maintain the crown of foliage, in the case of a choice variety, in as good

condition as possible, two or three incisions may be made in the stem, which should then be bound round with Moss, when from the wounded portions roots will push forth, and when sufficiently advanced the stem may be separated just below the ball of Moss, and at once potted. The same end is attained by breaking a small pot in two and encircling the stem with it, as if the pot is held in position by a bit of wire, it forms a good receptacle for the Moss, or other compost, into which the plant is required to root.

SOFT-WOODED PLANTS, such as Fuchsias, Bouvardias, Heliotropes, and a host of other things, kept partly at rest, should now be taken from their winter quarters, cleansed from all decaying leaves or other impurities, and placed in a gentle heat, when they will soon bristle with young shoots, which strike root very quickly. Sometimes, however, a few of the plants do not break into growth with the freedom that could be wished; this may, as a rule, be remedied by re-potting them in good, light compost, the stagnation in most cases being caused by the roots being in bad condition, frequently from the soil having become sour and exhausted; when in that state young healthy roots cannot make their way, and consequently the growth of the entire plant is arrested. Where the pretty white *Dentzia gracilis* is forced for early flowering, a good opportunity presents itself to obtain an almost unlimited stock of cuttings, for the shoots produced in the temperature of a forcing house will frequently commence to push forth roots while still attached to the parent plant, caused, doubtless, by the moist atmosphere. If these shoots are taken off at about 3 inches in length, the bottom pair of leaves removed, and then dibbled into pots of light, sandy soil, they strike root in about ten days, that is, if kept close in the same temperature as that in which they have been grown. If they are then potted off and sheltered by a frame till frosts are over, and then planted out, they make sturdy little plants the first season.

FERN SPORES.—The best time to sow these is about the end of this month and the whole of next, as the young plants then grow away without any check, which is not the case if sown late in the season. In the case of deciduous kinds it is, of course, necessary to secure the spores at the proper season, but in that of evergreen species it is totally different, as the spores can be gathered at any time. Where any are needed for sowing they should be at once gathered, and if folded in clean paper and laid in a dry place, they will be ready for sowing whenever required. Fern seed is all the better to lie for a week or two before it is sown. In choosing fronds from which to gather it, do not select those in which the spores appear very brown and ripe, as the probability is, most of their seeds have already dropped; but choose those rather in which the spore cases are just opening. T.

PROPAGATING HARDY PLANTS.

THERE is just as much reason why we should have propagating houses for hardy plants as for any other, yet we must often be contented with an odd frame or two for that purpose. The house we use for hardy plants is such as might be used successfully for any class of plants, from the softest, such as a Phlox, to the hardest, such as a Heath. It is a modern span-roofed house, 50 feet long, 9 feet wide, 4 feet high in the walls, and the angle of the roof is 50°. The walk down the centre is, I may say, 2½ feet wide; the beds are 3 feet wide, and their level is 6 inches from the glass at the back. The beds have slab bottoms, tight sides, and are filled with 4 inches or 5 inches of coarse, grey sand. Coarse silver sand would do, not fine of any kind, and red sand not at all. The hot-water pipes are boxed in, with flaps to let out heat into the body of the house during the coldest weather, a flow and return on each side answering our purpose. More piping could be added, depending upon the class of plants desired to be propagated. For Crotons, Stephanotis, Dipladenias, Allamandas, and Palm seeds bell-glasses could be used. One side, too, could be kept cooler than the other by means of

the valves. Such a house is clean, and the dangers arising from damp and mildew are lessened.

Our beds are used summer and winter. We take cuttings of anything we want whenever we can get them. But our most important season is winter, in order to meet probable demands in the coming spring. I have been successful with cuttings of *Achillea tomentosa*, *A. moschata*, and *A. Ptarmica* fl. pl. Although the majority of Asters come quickly from seed, yet with some, division or cuttings is about the only method by which they can be increased, and cuttings always make neater plants. The sorts to which I allude are *A. Auellus* and *A. alpinus*, their varieties and allies. Most Campanulas root as easily as Lobelias, and the cutting plan can be adopted wherever desired. In some cases it is required to take up plants in the autumn, wash the soil off them, and cut them up. This happens in the case of *C. garganica* and *C. Walsteiniana*, and probably others. Geraniums may be struck from root or stock, though it is slow work in the case of *G. cinereum* and *G. argenteum*. In the case of the double *Helianthus multiflorus*, flowering shoots make the nicest plants imaginable. There is a *Houstonia* (*H. rotundifolia*) which can be most efficiently increased by cuttings, by division, and also by seeds. In habit it resembles the pretty little *Veronica alpina*, or *V. repens*, as it is often called. This species of *Houstonia* is from Florida, and is a beautiful carpet plant. When in bloom it is just as lovely as *H. carulea alba*, the blooms being pure white. The creeping *Hypericum* will possibly all "strike," but *H. aureum*, probably the best of all decidedly shrubby kinds, comes so easily and quickly from seed, that I have never had occasion to try it from cuttings. I have the lovely *H. reptans*; also *H. Coris* and *Oenotheras*, particularly *H. missouriensis*. Of the latter, I usually take up a few plants in autumn and bring them along in heat, so I take cuttings, which form nice plants for sending out early, of the lovely *Osmunda tauricum*. Much has been written about its propagation: we have not the least trouble. I put in 200 cuttings (or, to express myself exactly, hackings or slips) last November, and 90 per cent. are rooted now (Jan. 10). It stands our winters unprotected in the open ground, and our winters here are not the ideal ones that are experienced east of the Alleghanies. The worst winter weather we have is that which is exceptionally warm following a period of frost and snow. Experience has told me that when we can plainly hear a certain steam pump in the vicinity, a blizzard from the north-west is nigh at hand. In less than twenty-four, sometimes twelve, hours the water and mud, which could not properly drain off on account of the ground not being thawed quite through, become frozen into a solid mass; then it is when the cold wind does the damage. The Oriental Poppy (*Papaver orientale*) can be increased quite easily from root cuttings. Petal-stemum decumbens, a lovely rosy flowered alpine, almost, if not entirely, unknown in Britain, will strike, but seed is better. This, when known, will prove a valuable acquisition. Underground species of *Polemonium reptans* root easily, but in very little heat, being liable to rot. Roots of *Saxifraga crassifolia*—in fact, all the *Megasea* section—increase readily from cut-up roots, as does also *Stokesia cyanea*.

T. D. HATFIELD.

Passaic, New Jersey, U.S.A.

Leaves for leaf mould.—I was rather surprised to note that Mr. Coleman recommends Beech for this purpose, as my experience is that Beech leaves are almost the worst that can be used. Against the others, Oak and Spanish Chestnut, I have no objection to urge. But Beech leaves are too hard, and more given to the production of a species of white fungus than almost any other leaves. Lime, Elm, Plane, and Sycamore form better mixtures with Oak than Beech, though most of these are almost too soft and perishable by themselves. They, however, soften, mellow, and enrich leaf-mould, and for general purposes probably form better leaf-mould than others with any large percentage of Beech. Again and again I have found Beech most mischievous as regards the diffusion of white fungi in fruit-tree borders, where leaf-mould made from it had entered even sparingly

into their composition, or had been used as a stimulant to start the roots off more freely.—HORTUS.

STOVE AND GREENHOUSE.

T. BAINES.

ROGIERA GRATISSIMA.

THE Rogieras are a small genus of Evergreen shrubs indigenous to South America; they consist of some four or five species, the first of which was introduced near upon half a century ago. But the kinds that first made their appearance have not met with much favour at the hands of cultivators, being rarely met with even in gardens where a feature is made of plants that are scarce and uncommon. The last of the species introduced, *R. gratissima*, is much the best of the genus, and is a real acquisition, yet so far it also seems to have made so little headway that to meet with it is a rare occurrence. Possibly this may in some measure have arisen through the plant having been described as requiring stove heat, and which has induced those who have undertaken its cultivation to subject it to a higher temperature than it could bear, a course of treatment that has caused many desirable plants to get a bad name. This is especially the case with such as hail from the same country (Mexico) as the species under notice, and which generally are found to do best in an intermediate temperature, or even in that of an ordinary greenhouse, as under the over-exciting influence of too much heat they keep on growing until their energies are exhausted, showing little inclination to flower in a way that admits of their merits being fairly judged. *R. gratissima* is more like the stronger-growing form of *Rondeletia speciosa*, *R. speciosa* major, in appearance than any other plant that I can think of, but the wood is stronger and longer-jointed than that of the *Rondeletia*, and maintains a more erect habit of growth when it gets old. The flowers are borne in comparatively large terminal corymbs, in shape like those of the *Rondeletia*, but larger and much more imposing in appearance; the colour is a pleasing shade of pink. The plant when well grown is a very free bloomer, flowering from the point of every shoot. It flowers in summer, earlier or later, according to the temperature it is subjected to. It will succeed fairly well under pot culture, small examples in 5-inch or 6-inch pots sometimes blooming as well in proportion to their size as larger specimens. But it is best adapted for planting out and training against a wall in a house or pit where it will get sufficient light. A dark position, such as the back of a lofty house affords, does not answer for it, the shoots coming long and straggling, whilst the leaves are wanting in substance to admit of their enduring as they should do. The end of a house that is composed of 2 feet or 3 feet of brickwork with glass above suits these plants well, and in such a position it will keep on in a thriving state for a lengthened period, flowering profusely.

It strikes readily from cuttings put in as early in the spring as they can be had in right condition. To insure their rooting satisfactorily, the cuttings should consist of young shoots, such as are usually forthcoming from branches that have been cut back to the hard mature wood; when they are a few inches long and have got a little firm, they should be taken off with a heel attached, inserting them singly in small pots in sand. Keep them fairly moist, and set them under a propagating glass in brisk heat and shaded from the sun. When sufficiently rooted, dispense with the glass and move them into larger pots well drained, using good turfy peat, to which

add as much sand as will maintain the soil in a healthy porous state, for it is well to bear in mind that this is one of the numerous sections of hard-wooded plants that have a dislike to any interference with their roots, such as occurs when submitted to shaking out with the intention of renewing the soil; consequently the material in which the young plants in their earliest stages are potted ought to be of a character calculated to keep the roots in a healthy condition for an indefinite time. When fairly started into growth, pinch out the points of the shoots so as to secure the plants being sufficiently furnished at the bottom; that is indispensable in whatever form they are to be grown. There is no necessity for a high temperature during the ensuing summer; about 60° in the night will answer, letting the heat rise proportionately higher in the daytime, and giving a little shade in the middle of the day when the weather is bright. Keep the atmosphere moderately moist with air until closing time in the afternoon; then syringe overhead. If all goes well the plants will require moving into 5-inch or 6-inch pots; this should be done before the summer is too far advanced to admit of the roots getting well hold of the soil before the season of active growth is over. Continue to treat as before until about the middle of September; then dispense with shade and cease syringing, giving more air. All through the growing season keep the plants well up to the light, without which they will be wanting in one of the first essentials to success—hard, well-matured growth. A temperature of about 50° will suffice in the night during winter, keeping the soil a little drier than whilst active growth was going on.

In the spring it will be well to decide whether the plants are to be allowed to flower this season, or whether it will be better to push them on, with a view to their attaining a larger size without the loss of time that their blooming will involve. If the latter course is followed, the points of the shoots should be removed before growth commences, and as soon as they have started, more root room must be given. If the pots they now occupy are well filled with roots, 9-inch or 10-inch ones will not be too large. The temperature should be kept up during the spring months similar to that advised last season, treating in the matters of air, shade, and moisture as before. As summer approaches, the sun-heat will be sufficient, closing the house in good time in the afternoons, so as to run up the temperature for a few hours, syringing the plants overhead at the same time, the conjoint effects of which with this, as with most other plants, do more to promote healthy growth than anything which can be done by the use of fire-heat. Where the plants are required to flower the year after they are struck, the potting will be best deferred until their blooming is over, shortening the shoots a little as soon as the flowers have faded, and when growth has commenced, shift them on into larger pots. Again, in autumn dispense with shading, and discontinue the use of the syringe, giving more air to get the growth matured: winter as before.

In the case of such of the plants as are to be turned out in a bed and grown either bush fashion or trained against a wall or the end glass of a house, as already suggested, the bed must be prepared and the plants transferred to it just as the growth is about to commence, not disturbing the roots more than is necessary, or it might have the effect of interfering with the flowering. After this the attention required consists in cutting back any shoots that take an undue lead, so as to distribute the strength evenly over the plants. When the roots have occupied the soil manurial assistance in a liquid form or by applying to the

surface a dressing or two of some concentrated manure during the growing season will be necessary.

NEW RACE OF CHINESE PRIMULAS.

THE suggestion (p. 44) as to crossing Chinese Primulas with a yellow-flowered species is worthy of further consideration. I know Mr. Barlow, of Stakehill House, near Manchester, tried crossing the Chinese Primula with varieties of the laced Polyanthus, and he showed me plants which he thought had some resemblance in leaf to that of a Polyanthus, although the seeds had been saved from the Chinese Primula; but I fancy the experiment was a failure. The most likely species to cross with *Primula sinensis* would be the deep yellow *P. floribunda*. The specific differences do not seem to be so far apart between these two as between *P. sinensis* and the common Primrose. So far the improvement in varieties of *P. sinensis* has been obtained by selection or crossing varietal forms of the species. Messrs. Sutton's single blue varieties are far in advance of any that have yet been exhibited at South Kensington, and I believe that if a yellow variety is obtained, it will be from the purplish blue varieties. The tint of some of these blue varieties are not far from that of the colour of the common wild Hyacinth, and from that colour numerous yellow varieties have been obtained. We may in the same way by chance get a yellow Chinese Primula. I would suggest that *P. floribunda* or the Polyanthus form of the Primrose with the deepest yellow flowers be crossed with the blue varieties of *P. sinensis*. Messrs. Sutton have been experimenting with *P. japonica* and *P. sinensis*, but, as far as I could see, not with any greater measure of success than Mr. Barlow obtained with the laced varieties of *P. vulgaris*. Some five or six years ago I crossed two distinct alpine species of Primula with deep purplish lilac flowers, and raised a distinctly yellow variety, which was exhibited at the Primula Conference; Mr. Churchill, who is well acquainted with alpine Primulas, said it was a yellow form of *P. pubescens*; at all events, I am quite certain that it was raised from two purplish lilac varieties, as I did all the work of crossing, saving the seeds sowing and attending to them myself.

J. DOUGLAS.

Boronia heterophylla.—In an article in THE GARDEN (p. 71) on the best Boronias no mention is made of this species, yet it is a very handsome kind, and one that should before this have become popular, for it has been introduced quite long enough to have been far more widely distributed than it is. I was much struck with its beauty a couple of years ago at Kew, and noted it then as in the way of *B. elatior*, but rather stronger in the growth and larger in the leaves. The most prominent distinctive feature is, however, the flowers, which instead of being rosy carmine, as in *B. elatior*, are rich vermilion, with a zone of pure white around the corolla. They are borne freely from the axils of the leaves and are agreeably scented.—H. P.

Epacris onosmæflora fl. pl.—The typical *E. onosmæflora* is a very old introduction, but, except in botanic gardens or in the collections of lovers of curiosities, it is rarely met with, the principal reason no doubt being that from an ornamental point of view it is inferior to the many garden hybrids now in cultivation. This last remark, however, will not apply to the double flowered variety, for it is not only totally distinct from any other Epacris, but is also possessed of high ornamental qualities. It is a stout, free-growing kind with long shoots thickly clothed with leaves, from the axils of which the small white rosette-like blooms are produced in such profusion that the whole shoot is a mass of white, that is to say, when the blooms are first expanded, as before withering they become slightly flushed with pink. This Epacris has now been before the public some few years, but no doubt two reasons have tended to retard its distribution. These are the apathy now entertained towards hard-wooded plants in general, and the fact that it is a difficult subject to increase, as

owing to the succulent character of the young shoots cuttings do not strike root at all readily. The most successful method is to keep the stock plant, whence the cuttings are to be obtained, warmer than usual, when the growth will be more attenuated; the weaker the shoots are the greater will be their chance of striking root. The best cuttings are obtained from a plant that has been shortened back but slightly after flowering, and then treated as just described. A length of 1 inch to 2 inches is quite suitable for the cuttings, and they must be dibbled into the pots very firmly, using sandy peat, and covered with a bell-glass till rooted.—H. P.

Brugmansia Waymanniana.—"W. G." asks (p. 46) if this plant is still in cultivation. From his description both of it and of the other Brugmansias, I fancy I have got it. "W. G." mentions but the other double, namely, *B. Knighti*, which is simply a double form of *B. arborea*, partaking of its unsymmetrical tube, which is bent, and too small in proportion to the mouth of the trumpet, and sharing also in the, to me, most offensive scent of *B. arborea*. But last autumn I was sent by a relative in the west of Ireland a plant with a bloom which was very different from *B. Knighti*. The tube was long and straight and well proportioned; the trumpet was fairly double or hose-in-hose, washed with purple, which, however, was not very conspicuous, and the scent was as delightful as that of Primroses. If the plant is not *B. Waymanniana*, I am at a loss to know what it is, as it certainly is not *Knighti*. Can the fine straw-coloured Brugmansia be merely a colour variety of *B. sanguinea*? It is so unlike in growth, being weak and straggling, spare in side growths, and decidedly more delicate. It is, as "W. G." says, rare; but if he has not got it I shall be glad to send him a couple of cuttings, if he gives me his address. I am always anxious to spread a good thing so far as I can do.—FREDERICK TYMONS (Clk.), *Cloghan, Co. Dublin*.

I well remember the purple Hose-in-hose Brugmansia about which "W. G." asks. It was to be seen every summer at a country house in Bucks up to 1861, but about that time it disappeared (with many other old favourites) under the rule of a gardener whose ideas were limited to two, viz. Grapes and Achimenes. I knew it as the purple Datura, and always supposed it to be *D. fastuosa* (Don), but it was certainly shrubby, though small, and therefore, I suppose, a Brugmansia. At Nice, thirty years ago, the single form abounded, and it may do so still. It was a greenhouse plant there (where *B. arborea* grows freely out of doors), and would have been much prized for indoor decoration but for its rich and overpowering perfume, which few could bear in a room. The flowers were about the size of those of *B. arborea*, but less graceful in shape; the texture was leathery and the colours very beautiful, purple outside and ivory white within. The Hose-in-hose form was not (so far as I remember) so strongly scented as the single one.—JUNIOR.

The Brugmansia, so well illustrated (p. 45), has grown here for many years, and when in full bloom is one of the most attractive of plants. It is one of the fastest-growing subjects with which I am acquainted, and therefore it would not answer to plant it out in a low house. The structure which contains it here is 14 feet in height, and in the growing season it soon reaches the roof. It has several stems about 3 feet in height, to which, as soon as it has done flowering, it is cut down. It re-starts and grows up again very rapidly. Cutting down is the only way of keeping it dwarf and bushy, and with plenty of feeding at the root it may be cut down three times in the season, when it will grow up again and bloom afresh. Its paper-white, trumpet-shaped flowers are often a foot or more in length. They are rather flimsy, and are absolutely useless when cut, as they fade rapidly; but they are so effective on the plants that I would not like to be without them.—J. M.

Cyrtanthus McKeni.—I was much pleased to see notice taken in THE GARDEN (p. 42) of this prime favourite of mine. Not a word too much

is said in its praise. I am surprised that so good a thing should be still so unknown, as it increases well under proper treatment. It may be well to impress on those beginning its culture that it likes abundant drainage, very firm potting in fibrous loam, enriched with a little thoroughly decayed old hotbed manure, and to be left undisturbed until the pot is completely filled with roots. It is an evergreen Amaryllid, and should never be subjected to drying off. My one original root has increased to some dozens, which I kept potting on as required until they were in a 12-inch pot. Then I split it up into four large potsful, besides putting several single bulbs into 4 inch pots. I have another variety which I believe is *C. lutescens*, and is in every respect the counterpart of *C. McKeni*, except that it is a lovely clear yellow. They make excellent com-

frame for a little while, and then the bulbs may be planted out.—H. P.

Early Tulips.—We always require as many flowers in December and January as we can possibly secure; we have therefore tried to force many varieties of Tulips to bloom about that time, but the one above all others which submits most readily to this treatment is the scarlet *Duc van Thol*—in fact, we have given them all up but this one, as we find it a very easy matter to have it in quantity from December onwards, and its bright scarlet colour is remarkably attractive during the short, dark days when bright flowers are by no means common. Some might think that *Poinsettia* heads were the most brilliant at that time, but the Tulips are more vivid in colour than even these are.—J. M.

Recent forms of Gloxinias. Engraved for THE GARDEN from a photograph by Mr. Heineman, of Erfurt.

panion plants. I wonder if there are any other colours among *Cyrtanthuses* of the same type as these two.—FREDERICK TYMONS.

Scilla sibirica in pots.—As blue flowers are by no means strongly represented among forced plants at this season, except amongst *Hyacinths*, the fact of the readiness with which this Squill can be forced seems to be generally overlooked, for it is seldom seen treated in this way, though it is as amenable to forcing as a Tulip. During the dull days of the early part of the year some pots of it form bright and cheerful objects in the greenhouse. With regard to the comparative merits of this *Scilla* and the newer *Chionodoxa*, I may say that here in rather an exposed spot the *Chionodoxa* is often greatly damaged by March winds, which the sturdier habit of the *Scilla* enables it to resist. Where this Squill is employed indoors after the blooms are over the pots should be sheltered by a

Gloxinias.—Few stove plants have shown more charming and novel variation during the last dozen years than the *Gloxinia*. The engraving is a reproduction of one of a beautiful series of photographs sent us by Mr. Heineman, the well-known seedsman of Erfurt. It is needless in our columns to say much concerning plants the cultivation of which is so well understood by our gardeners.

SHORT NOTES.—STOVE AND GREENHOUSE.

Forcing Lilies of the Valley.—It may possibly be remembered that last year I had something to say regarding Valley Lilies forced with plenty of leaves as well as flowers. In confirmation of this I sent you a potful in February. I have now some very good ones, and quite a mouth earlier than those sent last year. I have therefore had a potful photographed, and today I have sent you the self-same potful and also the photograph. They serve to show what can be done

with these Valley Lilies in twenty-one days from the day on which they were put into heat.—Wm. ELLIOTSONE, *Shipley Hall, Dublin.*

A beautiful plant, of which we shall publish an engraving soon.—Ed.

Primula flowers.—The different shades to be found in single *Primulas* are very pretty, but when cut they require to be carefully handled, as their coming in contact with other flowers frequently drags the blooms from their sockets, and they are at all times rather difficult to arrange effectively. The most charming of all ways of arranging them is to dish them up by themselves. If the colours are massed and mixed in a bowl, and not too much hidden with green material, the result is all that could be desired.—J. M.

SEASONABLE WORK IN PLANT HOUSES.

STOVE.—Tuberous *Begonia* seed should now be sown in order to have the plants in a condition to bloom satisfactorily during the ensuing summer. When sowing is put off until later the young stock has not enough time to allow of its acquiring the requisite strength to flower as it should do till the season is too far advanced. In preparing soil wherein to sow seed of almost any kind care should be taken that it is sufficiently light in texture, as if at all close and adhesive when the seedlings have to be removed from it the tender young roots are sure to get more or less broken, a mishap that it is necessary to guard against. Some growers use loam in which to raise seedlings of these *Begonias*, but unless it can be had of a free sandy nature I prefer peat, passing it through a fine sieve and adding some well decomposed leaf-mould and sand. Fill the pans with the material to within an inch of the rim, pressing it down so as to make the surface smooth, distribute the seeds thinly, and cover lightly with a little of the finest of the soil. In a temperature of 60° or a few degrees less the seed will vegetate; from the time that the little plants appear they must have plenty of light; in the absence of this they make weak growth. Whilst quite small they must be pricked off into pans or boxes an inch or two apart; if their removal from the seed pan is delayed, the roots, which are more impatient of injury than those of most things, suffer.

PERPETUAL-FLOWERING CARNATIONS.—Raising Carnations from seed is a very interesting proceeding, but to have a reasonable chance of varieties worth growing being obtained, seed from a strain that can be relied on must be at hand, otherwise the result is not likely to turn out worth the trouble. The seed should be put in at once, sowing them about an inch apart in a pan or shallow box, drained and filled with fine-sifted loam, a little leaf-mould, and some sand, covering the seed with about a fourth of an inch of the material, keeping it moderately moist—not too wet. To induce the seed to vegetate quickly, it should have a night temperature of from 55° to 60°; 5° or 10° less than this will do, but it will take correspondingly longer to get the plants up, and they will necessarily come on slower afterwards. As the object is to get the stock as much advanced as possible early, the seedlings must be kept until the weather gets warm in a temperature similar to that in which they were started. As soon as the little plants appear they must be stood close to the glass or they will spire up thin and weak—a condition that must be avoided. Directly they are large enough to handle, put them singly in small pots, using soil of a like nature to that in which the seed was sown; if a little rotten manure is added it will help them to gain strength. When the plants have got established, the weather may be expected to afford warmth enough without the aid of artificial heat, in which case a cold pit or frame will be the best place for them.

CELOSIA PYRAMIDALIS.—Where a good strain of this elegant-habited annual is secured and the plants are well managed, their usefulness for greenhouse and conservatory decoration can scarcely be overrated. The vivid tints of the reds and crimsons, and the soft agreeable shades of the yellow and straw-coloured varieties, are not surpassed by those of any flowers in cultivation, whilst for use in a cut state in combination with other

flowers of any kind, they are equally serviceable. The plants can be had in good condition through the greater part of the summer, and almost up to the end of the year, by making successional sowings, the first of which should be got in at once; a moderate sized seed-pan will hold as many plants as necessary for each batch. Use soil such as recommended for the Begonias, being careful not to sow too thickly, a proceeding that should always be avoided, especially in the case of plants that are raised under glass where the tendency in the seedlings to become more or less drawn up weakly is unavoidable.

AMARYLLIS.—The time for potting these plants depends on the time they are required to be in flower. Many growers start their whole collection at the same time, whilst others prefer to have them come on to bloom in succession. Such as are wanted early should now be repotted. The deciduous section may have nearly all the soil shook away from their roots, replacing it with new; rich turfy loam, with a little sand, will grow them well. In potting, ram the soil in the pots so as to make it moderately solid. Whatever offsets the large bulbs have produced, and which it is deemed desirable to separate, should be taken off and placed in separate pots. In severing them from the parent bulbs, be careful not to injure the roots more than is unavoidable. Give pots proportionate in size to that of the offsets, and treat in other respects like the old bulbs. In repotting the evergreen kinds, it is safer not to shake away all the old soil, but to leave, say, a third or a fourth of it, as sometimes when the whole of the material is got away it causes some of the leaves to decay prematurely, an occurrence that goes so far to weaken the bulbs. Where there is the means of giving them gentle bottom-heat for a time, in common with many bulbous plants, it will benefit them; but there need be no misgivings as to success in the cultivation of Amaryllis without their being assisted in this way. In a temperature of about 60° they will soon push up their flower-stems; and as they begin to move see that the plants are stood where they will get a fair amount of light. Do not give much water for two or three weeks, or until the roots and the top growth are in motion, after which, especially as the leaves begin to grow, the soil must be well supplied.

BOUGAINVILLEA GLABRA.—The flowering of this plant each season is not confined to the production of a single crop of bloom, as when started early and there is enough heat at command to push it on, the plant will flower two or three times. Grown in pots or when planted out this species usually produces a good deal of small shoots that are not strong enough to flower; these are best cut away before starting the plants into growth, at the same time shortening the strong branches from which alone flowering growth of any consequence may be looked for. If, as usual in the winter treatment of this plant, the soil has been let to get quite dry the ball must be thoroughly soaked; this is a matter of importance, as if the whole mass of soil is not moistened the growth made will be weak and puny. Syringe overhead once a day; afternoon is the best time. Where the plants have occupied pots as large as is desirable, a portion of the old soil may be removed, replacing it with new, made very rich with rotten manure; this species will bear more assistance in this way than many things would utilize; good turfy loam is the best for it. If the plants are to be trained on trellises, see that the sticks inserted in the soil and which support the trellis are sound and strong enough to last until the end of the season.

CLERODENDRON BALSIFOLIUM.—The flowers of this plant are much liked by some for cutting, whilst their enduring properties when allowed to remain on the plant make it useful for general purposes of ornamentation, and if when the flowers are open the plant is moved to a cooler atmosphere, they will last still longer. Small or medium-sized examples are preferable to large specimens for general use; plants started now in moderate stove heat will be

in flower in seven or eight weeks. With this *Clerodendron* it is also necessary to see that the soil is properly moistened when starting into growth. Except in the case of plants that occupy smaller pots than they are intended to be grown in during the ensuing summer, the potting is better deferred until the flowering is over.

ALLAMANDAS.—Where there is the means of giving these plants brisk heat they should now be cut back, and at the same time have the greater portion of the old soil shook away, repotting in new loam well enriched with rotten manure. In potting, ram the soil so as to make it more solid than necessary for most things, as when so treated the plants always flower better. I have found it best to re-pot Allamandas at the same time that the shoots are cut in; if they are allowed to break into growth before being repotted, as usual with most plants, many of the young shoots receive such a check that they refuse to move afterwards. Allamandas and Bougainvilleas that are planted out should now also be pruned, at the same time soaking the bed or border in which they are grown. As much of the surface material as can be removed without too much interference with the roots should be taken off, replacing it with new that consists of about one-fourth of rotten manure; this will not be too rich, as these plants are strong growers and require a great deal of support to keep them going through the long season that when vigorous they keep on flowering. The best sorts are *A. Chelsoni*, *A. grandiflora*, *A. nobilis*, and *A. Hendersoni*; the latter is one of the freest bloomers, but the colour of the flowers and the way in which the segments of the limb recurve make it the least effective, especially when the flowers are used for cutting, for which purpose the two first named sorts are the best.

GREENHOUSE.—Whatever training and tying is required by the hardwooded plants in this department should be completed without delay. For ordinary decoration nothing more in this way is needed than to support the branches in a manner that gives to each as much of the appearance natural to it as the circumstances of cultivation will permit of. Most of the hardwooded section of flowering greenhouse plants are naturally of a bushy habit, and when in the early stages of their existence due regard is paid to stopping the leading shoots, and keeping them well tied out so as to lay the foundation for their being well furnished at the base, much less in the shape of stakes and ties is required when the plants attain more size. With this object the young stock should receive especial attention in keeping the centres well open by tying the strongest shoots out horizontally, a position which they will ever afterwards retain, and in this way prevent the naked unsightly appearance that plants of the character in question, when they are thin and scraggy at the base, always present.

Rainfall at Bury St. Edmunds.—In THE GARDEN (p. 43) Mr. Uphill shows that the rainfall in 1886 at Dorchester was as much as 47.44 inches, an amount which contrasts very strikingly with the rainfall here, where the average annual fall during the last twenty-seven years is 25.71 inches, and the fall last year only 22.37 inches, or 3.37 inches under the average. The last month of the year furnished the largest monthly fall, being 3.33 inches, while the smallest was that of February, which amounted to only 0.24 inch, or less than one-fourth of an inch. Indeed rain did not fall during the month, and that mentioned was the result of melted snow. The largest annual fall here during the last twenty-eight years was that of 1872, when it amounted to 34.64 inches, and the smallest that of 1861, when only 16.44 inches fell. The following is the rainfall in 1886:—

	Inches.		Inches
January	2.14	August	1.26
February	0.24	September	1.00
March	1.58	October	2.82
April	1.15	November	2.57
May	2.63	December	3.33
June	0.46		
July	2.80	Total	22.37

FRUIT GARDEN.

W. COLEMAN.

ORANGE CULTURE IN POTS.

THE late Mr. Thomas Rivers, of Sawbridge-worth, some twenty-five years ago, began the culture of Orange trees in pots on a large scale, and grew delicious fruit of the little Tangerine variety as well as good examples of *St. Michaels* and the *Malta Blood*. I saw his trees growing in a heated house, and was so pleased with them that I determined to try the culture of the three varieties just named under the same conditions as regards temperature. In the West Indies Oranges ripen about the end of October in a temperature varying from 70° to 80°, and those who have been fortunate enough to obtain the fruit as it is gathered from the trees say that it is most delicious, far superior in flavour, indeed, to anything in that way obtained in England. Mr. Rivers' tropical orchard house was a well-heated and well-built structure, but when I began to cultivate Oranges I had to grow them in a house devoted to Melons and Pines. It was about 12 feet wide, and had a hipped roof. There were beds in the front for the Pines and Melons, and we placed a narrow stage against the back wall, wide enough to hold a row of Orange trees, and the temperature was about what they required. I soon found out that in order to grow good flavoured fruit it was necessary to maintain the highest hot-house temperature, viz., from 60° to 65° as a minimum in winter, and from 65° to 70° in summer. The day temperature was 5° higher, and with sun-heat in summer it sometimes reached 85° and 90°. The best trees we had, and those which produced the largest and best fruits, were worked on stocks raised from Lemon seeds. These were sown in a pot in the plant stove. They soon vegetated and grew freely, and in twelve months the plants thus raised were strong enough to be worked in the shape of dwarf plants. We, however, wanted some with stems 3 feet 6 inches high, and they made that height in two years from the time when the seeds were sown. The Lemon tree being the strongest grower of the two, makes the best stock if large trees are required. Grafting is an easy operation; when performed the plants ought to be placed in a warm house or frame, and kept close and moist. This is necessary to prevent shrinkage in the scions. If allowed to shrink by exposure to dry air the grafts will not unite, and will ultimately die.

I grafted standard and dwarf plants in this way without a single failure. The small Lemon trees, one year old, were in 4-inch and 5-inch pots. Being intended for dwarf specimens, these were cut over 6 inches or 9 inches from the ground. They will be found full of sap in February. With a sharp knife cut a slice from the scion, 2 inches long; to this the graft, after being correspondingly sliced, is firmly tied, no "tonguing" being necessary. It is useful that the bark of the stock and scion should fit at least at one side. Cover the union with a mixture of clay and finely chopped hay. The newly-worked plants should then be placed under a close handlight inside a vinery which has just been started. The cover of the handlights should be taken off, and the leaves gently dewed daily with a fine rose from a pot or syringe. Standards should be treated the same; but it is necessary over the top of the plant to place a bell-glass, which is made to rest on a small board placed below the union. If the hand-glass can be placed over a bed of gently fermenting material so much the better; in that case damping the leaves and grafting clay would be unnecessary. In three weeks a union will have taken place; this is indicated by the growth of the graft. In two weeks more the young shoots will have formed small leaves. It is now time to remove the clay and tying material, but this last must be at once replaced with some fresh raffia or soft matting, but not tied quite so tightly. Gradually admit air into the handlights, and when it is seen that the grafts are firmly established, remove the plants to a house where they can grow freely in a warm temperature. I have had fruit

to form and ripen on these young plants the first year. The flowers had, of course, been formed on the scion, but this is unusual, and if any fruit should set it is best to pinch it off. Fruit will be borne the third year; those who do not care to wait so long had better procure trees from some nursery. In one respect Orange trees differ from most other fruit trees, *i.e.*, they are always either in fruit or flower. A tree may be laden with golden fruit quite ripe; and it may also have small green fruits on it as large as Hazel Nuts, and likewise blossom. Oranges do not seem to require a period of rest; they are, indeed, perpetual bearers in every sense of the word. The flowering period is from January to March, and fruit may be gathered from them from September to March.

The old-fashioned way of growing Orange trees as greenhouse plants did very well if the object was to obtain blossoms only, or perhaps fruits, which were inside like the Apples of Sodom. Even the black peaty soil in which they grew was not adapted to produce sweet, juicy fruits. The soil in which Orange trees, cultivated to produce dessert fruit, succeeds best is four parts good turfy yellow loam, one part decayed stable manure, and to each barrowload of loam add an 8-inch potful of inch bones that have been boiled, and as much pounded charecoal. If the loam is of an unctuous character, add to it a portion of sharp sand. In potting, press the compost into the pots very firmly. I use for this purpose a wooden rammer, and the trees do not dislike a good large shift.

J. DOUGLAS.

FORCING STRAWBERRIES.

THERE is no fruit forced in spring or during the early summer months which gives so much satisfaction as the Strawberry, which is peculiarly attractive in all stages of growth. In some places there is a special Strawberry house, from which large quantities of fruit are obtained early in the season, but the majority of people who force Strawberries have no special houses for their production, and in that case they have to be grown in various structures in conjunction with other plants. Many first-rate Strawberries are produced in Pine stoves, vineries, and plant-houses generally. In such places, however, too early forcing must be avoided, as the plants under such circumstances have not the same chance to produce good fruit during the short days as they have in a house specially devoted to them. Market reports show Strawberries to be most valuable in February and March, but unless grown under the most favourable conditions, they are at that time deficient in flavour, and the crop is never so heavy as it is later in the season. Our most satisfactory crops of Strawberries are produced from the beginning of April onwards, and, although I have had them ripe in February and March, I now regulate the forcing so as to obtain the bulk of them during April and May; they are then secured in such quantities and of such good quality, that they more than compensate for any deficiency that may have occurred in February and March. When ripe at Easter they are very acceptable. Plants forced very early are apt to go blind or fail to produce anything like a full crop. April cannot be regarded as late in the season for early Strawberries, as it is quite two months or more in advance of the supplies from the open air. I would, therefore, strongly advise those who are not thoroughly experienced in such matters, or who have not the best of appliances for forcing, to aim at having their first fruits ripe early in April. I know that there are employers who insist on having Strawberries earlier, let the forcing appliances be what they may, but if they only considered how much finer their crops would be later they surely would defer their demands till they could be had in perfection. It generally takes ten weeks from the time when the plants are put in to force until the fruit is ripe, and I am greatly in favour of starting them very gently and growing them slowly until the flower-heads appear; then they will bear more forcing. It is absolutely

necessary that they should always be kept well watered, and it is a great advantage to keep them well up to the glass and in the full light. We find them to do exceedingly well upon a back shelf in a lean-to Pine house; immediately they begin to colour they are moved into a cooler pit to gain flavour and to prolong the succession. If a few plants of an early variety are put in to force now, and more about the first week in February, quantities of fine fruit will be produced by Easter, and a succession may easily be kept up afterwards.

J. MITCHELL.

FIGS ON THE EAST COAST.

MR. GROOM, of Gosport, recently favoured us with an interesting article on Figs on the south coast. It may probably surprise not a few of your readers to hear that the Fig does fairly well in the open air on the east coast, and in almost any warm nook or corner on walls throughout the eastern counties. Some of the finest Figs I have seen on this coast were close to the sea at Felixstowe. These were of several sorts—the White and Black Ischia, Lee's Perpetual, and the White Marseilles. They were stubby bushes that had been grown in pots for several years in pits, and had then been planted out against a south wall in poor, sandy loam and lime rubbish within sound and touch of the sea spray. The trees produced enormous crops of rather small Figs that ripened well, and were of excellent flavour. This was many years ago; but I believe these plants are still in existence, and probably ripening annual crops. A good deal of this success at the time was attributed to their close proximity to the sea. But possibly the effect of this was exaggerated, and for the encouragement of those that live so far inland as to derive no direct assistance from the saline spray or atmosphere, it may be added that Figs may be as successfully grown fifty or a hundred miles inland as on the coast.

What advantages there are on the coast probably arise from the higher and more equable temperature rather than additional grains of salt. Certain it is that attempts that have been made to supply Figs with more salt either in earth or air have not been encouraging, and that they can be grown to the highest perfection without any addition to our natural supplies of salt inland. But it is equally true that Fig leaves or roots are seldom injured by sea spray in moderation close to the coast. Of course, unless in specially warm localities, Figs in the eastern counties need to be backed up against walls or buildings to enable the fruit to ripen in the highest perfection. But this backing up does not mean training like thin skeletons over the surface Peach or Pear fashion, but the Figs are simply backed by the walls and allowed to scramble bush fashion over and in front of their warmest sides very much in the same way as the old Fig trees that had left the walls so graphically described by Mr. Groom.

The less dense the growth and the more limited the range of the trees from the walls the more heat they will enjoy; hence, the colder the situation the closer the Figs should be kept to the wall, and the thinner in reason the tops should be kept. Another chief means of commanding success is to use poor soil on a dry bottom. Protection, as a rule, proves a mockery, a delusion, and a snare, and those gather the most and the best ripe Figs in the open who ignore all protection, encourage short, sturdy growth, and prune but little.

D. T. F.

SHORT NOTES.—FRUIT.

The Pershore Plum.—We have for some few years back grown this Plum, which is much liked for preserving. This variety seldom misses a crop. —B. GIBBERT, *Burghey*.

Dicks-bill Apple.—A correspondent has sent me a sample of this Apple gathered from an espalier, which is said to invariably bear a good crop. The fruit, I may mention, is of Pearmain shape, medium in size, dark red on the sunny side, and yellowish green on the other. The flesh is remarkably firm, and I do not doubt that the fruit will keep sound until April. —J. C. C.

The Prune Damson.—In THE GARDEN (p. 26) I notice "B. C. R." giving this old favourite a name which it nobly

deserve. I was not aware before reading "B. C. R.'s" article that it was a Worcester production. It has been grown at Burghey from time immemorial, and for the last nineteen years in the majority of seasons it has always borne well. It is undoubtedly the prince of Damsons. —B. GIBBERT.

SEASONABLE WORK AMONG FRUITS.

FIGS.

SINCE my last paper upon this now popular fruit was written we have had more than a month of hard frost, repeated falls of snow, with a black, murky atmosphere, relieved by only three days of sunshine. These conditions, it is hardly necessary to say, have told heavily on the fuel store, and the progress has been extremely slow. Still, trees that have been forced for a number of years are now making a push, and a few weeks hence will be less backward than the inexperienced at the present time imagine. Judging from present appearances the worst of the winter is now over, but until milder weather has fairly set in it will be well to work on the give-and-take principle by allowing the night temperature to range low consistent with safety, and running up to a high figure whenever the sun again gladdens the earth. There are two distinct modes of managing or manipulating forced Figs—both good, as I have proved to my own satisfaction, and either of them being extremely simple they may be explained in a few words. The first and oldest is known as the close stopping principle, well adapted to old trees which have attained their full size, and generally show a great deal more fruit than they can carry to maturity. When these have made four to six leaves the points are crushed with the finger and thumb, or pinched quite out of the strongest shoots for the two-fold purpose of swelling up the early shows and inducing another break for giving the second or succession crop. If started very early and the trees are highly fed, they may be made to carry three crops, but nothing is gained in the long run, as the third crop which comes when Figs are very plentiful interferes with the season of rest, and not unfrequently results in the loss of the first crop in the ensuing spring. Short spur-like pieces of wood do not require pinching, as the fruit which they carry checks growth, and having sound plump buds they always set plenty of embryo Figs ready for swelling when the strain of the first crop is over. Constant pinching induces the formation of a great number of side shoots, and light as well as air being such important elements it is often necessary to cut away many of these to insure an even spread of foliage the reverse of crowded. Close pinching results in two distinct crops of fruit, the first from the embryo Figs formed near the points of the shoots of the previous year; the second from the spring growths, which I have just suggested stopping at the fourth to the sixth leaves, with, as a matter of course, an intervening period in which there are no ripe Figs fit for use. By the other, *i.e.*, the extension system, which best suits younger trees having plenty of trellis room, the supply of fruit from the beginning to the end of the season is continuous, as well-fed trees are constantly extending and forming young fruit in the axil of every leaf. In course of time the most advanced shoots reach their limit, when shortening back to a dormant eye whilst making room for others to extend ensures a relay of young wood all over the tree for succession. Whichever system is adopted the young fruit and foliage now making good progress will require copious syringing with tepid water, not forgetting the small bag of soot submerged in the cisterns, at least twice every fine day. When the weather is unfavourable to ventilation and evaporation the walls and floors only must be syringed, atmospheric moisture and ammonia at such times being secured by the frequent turning and renovation of the fermenting material. From this time forward liberal supplies of diluted liquid must be given to the roots, otherwise spider will become troublesome and the trees will most likely cast the finest and, as a matter of course, the most valuable fruit. More heat, too, may be given, especially in genial weather, when the temperature may range from 56° to 60° by night, 65°

to 70° from fire-heat through the day, and 70° to 80° when the sun is shining and air can be given.

Succession houses recently started will require supplies of tepid water at short intervals to ensure a thoroughly moist condition of the soil before the buds burst into leaf. When properly moistened old trees may be well mulched, but young ones will not be improved by the use of stimulants in any form, at least for the present. This remark, of course, applies to trees established in internal borders, as it is always possible to feed at the proper time, but very difficult to check gross growth—the most common cause of the fruit dropping when they are too highly fed at the outset.

Young stock.—If young trees of last year's propagation still remain dormant they may now be started in a moist, genial atmosphere, reduced and re-potted when the buds show signs of swelling. If fairly formed by the end of the past year the young shoots will most likely ripen a few fine Figs after the turn of the year, but all depends upon the purpose for which they are being grown. If for forming large bushes or pyramids the few fruits they might carry should not be taken into account until they are well furnished with good bearing wood worth forcing. Cuttings or eyes should be put in without delay, and after they have stood for a short time to heal they may be plunged in bottom heat and treated precisely the same as Vine eyes. The cuttings should be made of short, well-ripened pieces of wood having good terminal buds and a heel, or an inch of two-year-old wood at the base. Every bud likely to be buried in the soil must be removed before the cuttings are inserted, otherwise suckers will be found troublesome.

THE ORCHARD HOUSE.

As some of the trees in the early house will soon be coming into flower steps must be taken for ensuring freedom from aphid during the time the fruit is setting. Some syringe with a strong decoction of quassia, but I give preference to the fumigator for the simple reason that tobacco smoke permeates every part of the house more effectually than liquid through the syringe. The trees should be perfectly free from moisture and the day calm when the fumigator is introduced, and the weather being dull a second smoking may be performed before they are syringed, a very important operation which should always precede exposure to bright sun. When the trees are clean syringing, always with a rising temperature, must be resumed and continued until the flowers begin to expand. This stage reached, a somewhat higher and drier state of the atmosphere, with a nice circulation of air, always provided cutting draughts can be avoided, will favour the setting of the fruit. To secure these conditions the pipes, unless the weather is very bright and mild, should be kept constantly warm, and the better to prevent the air from becoming too dry the pots and lower parts of the stems of the trees may be syringed with tepid water every day. Fruit growers at one time thought Peaches, Vines, and other fruits could not be kept too dry when in flower, but many now recommend syringing, whilst others take an intermediate course and fertilise with a camel's-hair brush when the air is light and buoyant and the pollen flies off in bright golden showers. When the latter method is adopted the pollen from robust sorts like Royal George Peach and Elrube Nectarine is generally selected, and the large flowered section of Peaches and Nectarines is considered most in need of careful attention. Whichever mode is decided upon the great secret of success lies beneath the surface of the soil, for unless the roots are healthy and active and properly supplied with genial warmth and moisture the syringe or the brush may be pried in vain. If this were not the case all experts would not so rigorously insist upon trees being thoroughly established in well drained pots before they are taken in for forcing.

Pruning and disbudding.—I have often advised the inexperienced to defer shortening back until

the fruit is set, as they then escape the dilemma which dropping or mistaking a flower for a wood-bud might place them in. Shortening the shoots before disbudding is commenced does no harm, if it does not actually benefit the fruit, and having secured a good set near home, pyramids and bushes can be reduced to shape with good leading growths from every point. If the trees were thoroughly ripe and have not been hurried, the young growths will not be in advance of the fruit, and disbudding will be found a very simple operation. The first thing to be secured, be the tree a bush or pyramid, is a good leading shoot to draw the sap, and another, starting from near the base, for bearing fruit in the following year. These two generally furnish a well-formed tree, but it sometimes happens that an intermediate shoot may be needed, when three must be left. All others, in the first instance, should then be pinched to two or three leaves and eventually removed, unless well placed fruits are swelling at their base, when a short spur, furnished with a few leaves, will help them forward. Pinching should be performed piecemeal, commencing at the top of the tree and working gradually downwards, taking all the strongest shoots first and leaving weak ones to gather strength, or perhaps form short spur-like pieces of wood, which the loss of the terminal bud would render useless.

Top-dressing and feeding.—It is not a wise course, as soon as the fruit is set and the trees are disbudded, to heap on powerful top-dressing, as strong stimulants at this stage very often induce a gross habit of growth before they feel the weight of their load. Mild diluted liquid may, however, be given twice a week, and the trees must be well syringed once or twice a day. Meantime the top-dressing, previously prepared and kept covered up with fresh horse manure in an open shed, should be examined and turned, to thoroughly incorporate the loam, which is the staple, the manure and bone-dust ready for use. This, when the fruit is swelling freely, may be placed on the tops of the pots, in small quantities at first, and supplemented as often as it is washed in or loses its virtue. As growth proceeds, and the young foliage, by its size and colour, shows signs of too much or too little vigour, the strength and quantity must be regulated; and here it may be well to remind the tyro that moderation until after the fruit is stoned is the best and safest course to follow. When this process is complete more liberal supplies of food may be given to trees carrying full crops of fruit; and clarified liquid, also soot water, may be used for damping the pots, stems, and floors of the houses.

Succession houses.—If any of the trees still remain out of doors no time should be lost in getting them housed and placed in position for the season. If a mixed collection, Figs should occupy the hottest part of the house. I take it for granted that every orchard house is fitted with a flow and return pipe, if only for ensuring a set of fruit. Peaches and Nectarines should follow, Pears, Plums, and Cherries bringing up the rear. If large trees in medium-sized pots must be let into the borders, I would suggest placing them on two bricks, with the apertures immediately over the joint, for the double purpose of allowing the free passage of water and preventing the roots from rambling beyond control. If, on the other hand, it is necessary to elevate them on inverted pots or pedestals, then a good sod of old pasture turf, Grass side downwards used as a cap, will save labour when hot weather necessitates constant watering, and prove a safeguard should the soil in any of the pots become too dry. When the trees and pots are washed and placed, a good supply of lime-water will settle the account with any worms which may have got into the balls during the winter, and they will be ready for starting upon the lines laid down for early trees, or, lacking fire-heat, the house must be freely ventilated to keep back the buds until all danger of a nipping frost has passed away. So important, however, and so cheap withal is a simple heating apparatus, that I cannot once more forbear asking those who

have not introduced one to do so without delay. Many a houseful of trees has been wrecked by a single night's frost when in full bloom. More perhaps have failed to set through the petals and pollen becoming damp and pasty in a low, murky atmosphere, and how many become barren through the want of a ton of slack to ripen up the wood in the autumn it is impossible to calculate.

A good slow combustion boiler needing no setting can now be bought for £3 to £5, and pipes with screw joints can be fixed by unskilled labour. For a long time I was prejudiced against these diminutive boilers, but having had two in work for some years, I can strongly recommend them for doing an immense amount of work in large houses in the spring and autumn, and for protecting Chrysanthemums from frost and that subtle enemy, damp, in winter. If Strawberries have been prepared for fruiting in the succession house, a good batch of plants should be well rammed to settle the frost-lifted soil, top-dressed, and placed on the floors, where they may remain until the crowns show signs of swelling. In this position they will make roots and start quite as well as on the shelves, and standing on a damp surface the balls can be kept moist by the occasional application of water; whereas on dry, airy shelves their wants will require daily attention. Vicomtesse Haricart de Thury, La Grosse Sucrée, Sir Charles Napier, Comte de Paris (a good form of Keen's Seedling), and Prince of Wales are good sorts for coming in early and producing heavy crops of fruit. President, Sir Joseph Paxton, and the Queen come later, and in order to secure a good succession, may remain in cold frames until the end of February. Strawberries this season have had a most decided rest, and cultural conditions being equally favourable, well ripened crowns should make a bold start and flower profusely.

GARDEN FLORA.

PLATE 581.

CARPENTERIA CALIFORNICA.*

THE accompanying illustration of this beautiful new Californian shrub represents it so well, that a description of it is scarcely necessary. It is one of the latest introductions to our gardens from the flowery west, and promises to prove a really good garden plant. It may, however, we fear, be too much to say that it is a perfectly hardy shrub, except in such favoured spots as the Isle of Wight, the Devon and Cornish coasts, and the warm and moist southern parts of Ireland. The most successful cultivator of it we know is Miss Jekyll, who has some fine plants of it in her garden at Munstead, Godalming, and that part of Surrey is not one of the best for tender plants; but then she grows it against a wall, and chooses for it the most suitable spot that can be found. She was, we believe, the first to flower it in England, and perhaps in Europe, and from the plant that flowered at Munstead last June the present plate was drawn. Miss Jekyll speaks of it as a free-growing and free-flowering shrub, which, we believe, corresponds with the experience of others who grow it. In Mr. Gumbleton's garden at Belgrove, Queenstown, it grows at a rapid rate, and six or seven years ago he wrote in the highest praise of it. Now that it has become well distributed about the country it would be useful to hear from growers of it in different parts as to its behaviour, more especially in reference to its hardiness. We believe that it has not been thoroughly tested fully exposed, and until it becomes commoner it is not advisable to plant it away from the shelter of a wall. The soil at Munstead, where it grows so well, is light and naturally very dry and warm in summer. It is readily increased by cuttings or rooted suckers, which it produces freely.

* Drawn for THE GARDEN at Munstead, Surrey, June 27, 1886.

CALCEOLARIA CALIFORNICA

The *Carpenteria* is a new plant in every sense of the word. A few years ago, when the "Botany of California" was written, it was not perfectly known to the North American botanists, for no flowers (only fruits) had been seen upon the specimens then collected. The information, therefore, that botanists can give us is consequently very meagre. It is described as a tall shrub from 6 feet to 10 feet high when fully grown, having slender branches clothed with long narrow leaves of a pale green colour, and producing great clusters of large white fragrant flowers. It grows wild in the mountains of the Sierra Nevada, particularly about the head waters of the San Joaquin River. The *Carpenteria* as a cultivated plant has no history. It somehow crept into English gardens in a mysterious way, and without the trumpet-flourish that usually heralds the advent of a beautiful new foreign plant. The first we heard of it (and probably before anyone else in Europe) was from Mr. Saul, of Washington City, D. C., U.S.A., who sent us dried specimens of it in 1880, and from these pressed flowers and leaves the first drawing of the plant seen in this country was made. It is, botanically, nearly related to the Mock Oranges (*Philadelphus*), which it somewhat resembles. There is but one species in the genus, and therefore it is monotypic, as the botanists say. It is a singular fact that there are several genera in the same Order to which the *Carpenteria* belongs represented by only one species, among these being *Jamesia*, *Fendlera*, *Cardiandra*, and *Decumaria*.

FERNS.

W. H. GOWER.

SWEET-SCENTED FERNS.

WHILST some plants are valued for the brilliancy of their flowers, others are scarcely less appreciated for their agreeable fragrance, and a third class, in which are included the Ferns, depend for their popularity upon the grace and elegance of their fronds and their vivid shades of green. Amongst Ferns especially, few would expect to find sweetness in the way of scent, yet some few members of this family have this additional charm. The following, therefore, are a few which may claim to be designated sweet-scented: *Lastrea æmula*, the Hay-scented Buckler Fern, a robust-growing plant, has a stout, creeping root-stock, from which its fronds are produced. These are erect, from 1 foot to 2 feet in height, twice divided, and narrowly oblong in outline, pale green in colour and agreeably fragrant, both in a fresh and dried state. It is found in various parts of England, but not everywhere. The Mountain Buckler Fern (*Lastrea montana*) is another of our indigenous plants which must not be overlooked. It has also a creeping root-stock, and the fronds vary from 1 foot to 2 feet in height by about 6 inches in breadth; they are lanceolate in outline, arching, and pale green. Its general aspect is that of the Male Shield Fern (*L. Filix-mas*), from which, however, it is easily distinguished by its fragrance when shaken or rubbed. It is found mostly in our northern and western counties; it also occurs in Ireland, but is most plentiful in Scotland. *Anemia tomentosa* is a tropical American plant, and, as the annexed illustration shows, belongs to the section popularly known as Flowering Ferns. The whole of this family are handsome, dwarf-growing plants, requiring stove heat, but the fronds of this particular kind give off a strong odour of Myrrh. *Cheilanthes fragrans*, one of the Lip Ferns, is a dwarf plant suitable for the greenhouse. It produces fronds about 6 inches in length, by about an inch in breadth, deep green above, but paler below; these are delightfully fragrant—almost

as sweet as Violets. *Lastrea fragrans* is a small-growing hardy Fern found in North America; it produces oblong-lanceolate fronds some 9 inches long, and deep green, with a fragrance which some liken to that of May. *Lindsaea cultrata* is a Fern common in Northern India, but not plentiful in cultivation. It is a dwarf plant with a slender creeping root-stock; fronds from 6 inches to 1 foot long, and about 1 inch broad. They are once divided into segments about half an inch or somewhat more long. They are what is termed dimidiate; that is to say, the whole leafy portion is developed upon the upper side of the mid-rib; they are pale green, and yield a powerful odour resembling that of sweet vernal Grass, and which they retain a long time after being cut. *Sitobolium punctilobum*.—This hardy kind, the sweet-scented Fern of the Americas,

may be likened to a long, narrow-fronded form of *A. cuneatum*; the fronds in a young state are slightly tinged with pink, and yield a perfume resembling that of Cowslips or Primroses. It is a most serviceable plant for cutting from, and to the bouquetist its scented fronds are a decided acquisition.

SHORT NOTES—FERNS.

Hart's tongue (*G. Morron*).—The Hart's-tongue Fern, stated to have been found by you at Gibraltar and in several places in the Mediterranean, is, in the absence of specimens, we imagine, *Scolopendrium Hemionitis*. At the base of this Hart's-tongue are rather large, pointed lobes, which give the fronds a somewhat spear-shaped outline. It is a handsome plant, but whether obtainable in this country or not, we cannot say.

Fiji Hare's foot Fern (*Davallia foveolata*).—This is a distinct and handsome plant, and somewhat new to culti-

Anemia tomentosa (fertile frond, half natural size).

is very odoriferous when shaken or rubbed; its fronds are about 18 inches high, three times divided, the ultimate segments being small and vivid green in colour. It is an elegant plant for the outdoor fernery, contrasting strikingly with our native kinds. *Muhria thurifraga* is an elegant species from Natal, suitable for the greenhouse; its fronds, which are erect, are from 9 inches to 18 inches long, and three times divided into small-toothed segments, which, however, become obtuse when fertile; the stem and mid-ribs are clothed with reddish hairs; the fronds give off a strong aromatic odour, resembling that of benzoin. *Asplenium fragrans* is a West Indian plant, resembling somewhat the English black Spleen-wort; its perfume resembles that of newly-cut hay. *Adiantum fragrantissi-*

um, although found in the Fiji Islands many years ago by Milne when attached to the expedition of H.M.S. *Hecla*. It has a creeping, short, thick scaly root-stock; the fronds, which are gracefully arched, are from 1 foot to 2 feet high and nearly a foot broad. They are about four times divided, the ultimate segments being long, narrow, and forked at the ends, whilst the colour is an intensely deep green. This plant is just now very conspicuous in the fernery in the Holloway Nursery.

The preservation of our native flora.—I have just received from M. Correvon, of Geneva, a pamphlet regarding the method of plant-preservation in Switzerland, with rules of the society formed for that purpose, and a short account of the valuable work done since it was instituted four years ago. Strange as it may seem, the method adopted by this Swiss society for preserving rare plants is similar in almost every respect to what I have frequently suggested should be done in our own country, and quite lately when the erection of *Spiranthes Romanzoviana* was attracting attention. It is to be hoped that the work of this Geneva society, under M. Correvon's guidance, will be attended with good results, and be the means of preserving many of the now rare plants

of the Alps. The sooner an English society of the kind is formed the better, if our notice be given to preserve even in its present shattered condition.—A. D. WILDSMITH, *Leeds, Broomfield, Broomfield.*

KITCHEN GARDEN.

W. WILDSMITH.

BEST FORCING KIDNEY BEAN.

FOR many years Osborn's Forcing was generally selected for the earliest crops, and, as far as quality is concerned, I am inclined to think it still the best. Of later years Ne Plus Ultra has become first favourite, and, on the whole, it may safely be said to be the most profitable early variety in cultivation. Osborn's Forcing is scarcely robust enough, and three or four good pickings are usually the extent of its crop. If gathered before it is too old to snap in two readily and used at once, its colour is certain to be good and the quality unequalled. Our cook could always tell if we had kept them with their stalks in water for a day or two, and he has repeatedly asked us to do without it if possible, this treatment tending to make them hard when boiled. The same remark applies to any variety of Kidney Bean, but in most cases they have of necessity to be frequently placed either in water or bunched and put on damp, clean Moss. The plants must be gone over almost daily and the most advanced gathered, otherwise they soon become old and tough, and when the hamper of vegetables for the town house is only sent bi-weekly, it follows that something must be done to keep the Beans fresh. They ought to be stored in a comparatively cool room or shed, and if water is employed it should be frequently changed, and the pans or saucers scoured out.

NE PLUS ULTRA, if the true sort is obtained, is rather more vigorous than Osborn's; it is equally early and quite as free-bearing. Than this no other sort is now grown here, either in pots, boxes, or pits. At one time we were obliged to augment our later supplies with Canadian Wonder, but this and other strong growing varieties, although longer in the pod, require too much room to be profitable. Many sow the seed in 3-inch pots, shifting the young plants into larger pots later in the season. If space is limited, there may be something to say in favour of this plan; otherwise, it has nothing to recommend it. Most people are in the habit of only two-parts filling the pots in which they intend to grow the Beans, completing the filling with rich loamy soil when the plants are growing strongly. This practice involves an unnecessary amount of labour without any compensating advantages. Very frequently the top-dressing is never occupied by the roots, and more harm than good in that case is the result. Our plan is to sow the seeds in the pots, leaving, after the seeds are covered, about the depth of the rim for holding water. For the very earliest supplies 8-inch pots are large enough, but later on 9-inch pots are preferred. These will stand on comparatively narrow shelves or ledges, and if properly attended to will produce a good crop of Beans. Very little drainage is needed, and this being covered with a little rough manure, the latter prevents clogging, and affords good food for the roots. In order to hasten germination, the seeds may be soaked for a few hours in a pan of water set on the hot-water pipes, and the soil being warmed for their reception, no check is sustained. Our earliest batches are usually started on the hot-water pipes, and transferred to a warm and lighter position before they become badly drawn.

In order to maintain a continuous supply, fortnightly sowings are necessary, and a batch of twenty-five pots, each containing about six plants, is usually ample for affording a good-sized dish at a time as required. The plants can be readily supported with sprays from old birch brooms, and, failing these, a few sticks and two or three encircling strips of matting will keep them together equally well. Where more seed is sown than plants are required thinning out should be

done early. At no time should the seedlings suffer from drought, either at the roots or in the atmosphere; frequent gentle syringings overhead and liquid manure after the plants have commenced to bloom greatly benefit them. An ordinary stove temperature suits them well. Many are obliged to grow them in early vineries, but this should be avoided where possible, no class of plants being more liable to be infested with red spider. If heated pits are available, these are usually well adapted for Bean culture, especially for affording a succession to the earliest crops from pots. A mild hotbed, consisting of leaves and manure and about 9 inches of good loamy soil, suits them well. We prefer to raise the plants in small pots, two or three in each, and put them out thickly in rows about 15 inches apart. The very latest spring supplies are drawn from plants put out in unheated frames in succession to early Potatoes, another large batch of plants being put out on a sunny border and protected with hand-lights just liberated from Cauliflowers. According as the sun gains power so the difficulty of growing Beans in pots in a clean profitable condition increases; in fact, they require more attention in the shape of waterings and syringings than they are worth. During hot weather, and, indeed, any time after March, they succeed better in boxes than in pots. These may be of any length, but of a size to fit the shelves, and with rough loam or manure for drainage and good loamy soil for the plants to root in, very little water is needed. In boxes the plants remain more healthy and last longer in bearing than those in pots do, especially if not unduly crowded. One good row in each box is ample.

W. I.

Self-protecting Broccoli.—By selecting varieties of Broccoli that come into use at different periods an almost unbroken supply can be maintained during the greater part of the year in ordinary winters. One of the best is Veitch's Self-protecting, which comes into use when the Autumn Giant Cauliflower is finished. It produces large heads of a particularly clear white colour, firm, and of fine shape. In order to have a crop to succeed the Giant Cauliflower, a sowing should be made upon a warm south border the last week in March, or, better still, in a cold frame. In the latter the seedlings will come up earlier and be ready to prick out at the bottom of a south wall, where they will get strong and stocky. They will then be ready to plant out finally about the middle of May. This crop will be ready to cut by the time the latest crop of Giant Cauliflowers is over. The main crop of Veitch's Self-protecting Broccoli should be sown from the 8th to the 12th of April. The young plants have then time to make their growth and mature it before commencing to form their heads. The stalks must be well hardened before the button commences to form in the crown of the plant, or one need not expect a head of well-finished Broccoli. Plants growing in shady places or underneath trees, even if the stalk or stem is as strong as that of plants in open quarters, only produce small and imperfectly-formed heads; and it may be observed that the usable parts of plants growing in such situations are found to be deficient in flavour. Broccoli of this description is not comparable with that produced in the fields. The latter have fine dark-coloured stems and beautiful close, compact heads, fit for any table. The seeds may either be sown upon beds broadcast, or in drills 3 inches apart. As soon as the plants are large enough to handle, prick them out 3 inches asunder upon a piece of ground which has been well firmed. Some time during the latter part of June plant them out upon a piece of ground which has been deeply dug and well enriched with rotten manure. Plant 21 inches apart row from row and 18 inches plant from plant, treading the ground firm in the rows. I commenced cutting my earliest planted Broccoli the first week in November, and had a continuous supply of fine heads up till Christmas. I lifted a number of plants and planted them in a light airy shed. They had partly formed their heads before being lifted, and the latter developed

properly, and have only been finished a few days ago. The leaves of this variety afford the heads more protection than any other variety with which I am acquainted. They twist over each other very closely, and I think this Broccoli may be said to be tolerably hardy. A few plants which still remain look as if we might get a few heads yet from them before Snow's Winter White is ready to cut.—WM. CHRISTISON, *Homewood, Bromley.*

GOOD VEGETABLES.

LETTCES.—I have never seen mentioned in the lists of desirable varieties of this most useful article of salad, which have from time to time appeared in THE GARDEN, a kind which I myself have grown for several years called Bossin. It is greatly liked and admired by all who have seen and eaten it. I first got to know of it through getting a packet in a collection of vegetable seeds from the Royal Horticultural Society, and was so much pleased with it, that I looked through catalogue after catalogue with a view to growing it in the future, and at last, by good luck, found it in a list sent me by Messrs. Vilmorin, of Paris. The Bossin Lettuce is one of the Cabbage varieties. The outer leaves are slightly bronze, but the hearts, which are very solid and of a large size, are light green, the leaves being tender and crisp. It stands the hot weather well, showing no tendency to bolt. The seeds are black.

CAULIFLOWERS.—Do any of your readers know a new early variety of this vegetable called Extra Early Sea Foam? It was offered last year by an American firm from whom I procured seed. It proved to be a very desirable sort. It is rather earlier than Sutton's First Crop, which I have always grown before, and consider a most useful variety; it is also superior to the latter in the flower, which is closer and whiter. I intend to give them another trial this year. As a succession to the above mentioned sorts, I do not think Sutton's King of Cauliflowers can be beaten. I always get it myself and find it most satisfactory.

CHOU DE BERGHELY.—Can some of the readers of THE GARDEN kindly give me some particulars of this vegetable, which is so highly praised on all sides? I should like to know when it is considered to be in season, and the best way of cooking it. I had a few plants of it last year, but I am afraid they have been spoiled by the recent severe weather. Has it come true when the plants have the appearance of a sugar-loaf Cabbage with a sprout growing at the foot of the leaves?

F. R. H. S.

A new esculent (Coleus tuberosus).—M. Paillex publishes the following in the *Moniteur d'Horticulture*: "On the 15th of July, 1884, a correspondent in the Transvaal, M. Mingard, wrote to me as follows: 'With this letter I send you some tubers of the wild Potato called by the Magbambas, Matambala. It is grown like the ordinary Potato and is used in the same way. The natives highly value it, preferring it to all other tuberous-rooted esculents. They keep the seed tubers either in dry sand or hung up in their huts. They are planted at the sowing season of the Maize.'" M. Paillex has been successful in getting a few good tubers of this esculent in good condition. These were planted in a frame and did well. The following year a mistake was made in watering up to too late a period, so that many of the tubers rotted. M. Paillex thinks that if planted in June and taken up in September, very good results would be obtained. It is a curious fact in connection with this tuberous-rooted Coleus that it was described in an old work by a certain M. Placourt, director-general of the French East India Company, so long ago as 1661. The author was at one time commandant at Madagascar. His description of it is: "Roots small, about as large as one's thumb, and increasing exceedingly, one plant yielding upwards of two hundred." Until M. Paillex received his tubers this plant had never been introduced into Europe. It is rather strange that this

esculent should be cultivated at Madagascar and the Transvaal, and it would be interesting to know if it is now a staple article of food in the former place. It is said to prefer a light soil, and undoubtedly likes a warm climate. In the south of France it ought to do well.—J. CORNHILL.

Early Cauliflowers.—When nice fresh Cauliflower heads can be had about the first week in June they are most acceptable, and now that we possess so many early sorts, that need not be difficult. The old plan of sowing in August or September and keeping the plants under glass during winter entails a great deal of labour, and therefore we have ceased to follow it, and now sow in spring. If seed of some of the earliest sorts is sown now in gentle heat the young plants will appear in a week, when they may be grown slowly on until the end of March and then they should be planted out. If kept near the glass and not allowed to become too crowded they will be found to be much more healthy and robust than plants sown in autumn and wintered under glass.—CAMBRIAN.

Early Peas.—It is now time to think of these, and where open-air conditions are unfavourable to early growth the plan of raising the young plants under glass should be adopted. If not grown in too much heat, plants raised under glass are very useful, but when kept very close in strong heat until they are 10 inches or 1 foot high and then planted out without being properly hardened, little or no success need be expected. We raise quantities of early Peas under glass, especially new early ones, which we wish to make the most of and are afraid to trust out too early, and when the young plants are from 4 inches to 6 inches in height, sturdy and very dark green in colour when planted, they invariably do well. The best of all the ways which we have tried of raising Peas under glass is to sow ten or a dozen seeds in a 3-inch flower-pot, and plant them out of these without breaking the balls of earth. When in pots they can be conveniently moved about or placed further apart to prevent crowding, and one or two hundred pots make a grand batch. In planting them out it is unnecessary to put them in so close as to touch each other, for even if each little clump is kept 6 inches or so apart, the row when they grow up will be complete.—J. MURR.

Early Leeks.—These need never be grown extensively, but a few dozens of them are easily managed, and when grown to weigh 3 lbs. or more each in August they are useful either for exhibition or other purposes. A pinch of seed should be sown in a 6-inch pot, and if placed in a little heat it will germinate in three weeks or so. The plants should then be kept near the glass and in a temperature of 60°. As soon as they can be handled lift them from the pot and dibble them into shallow boxes in very rich soil. Keep them about 2 inches apart, and they may remain in the boxes until they are planted in the open ground. This should be about the end of April or early in May, and if put out in trenches like Celery their growth will be found to be most satisfactory. Apart from big Leeks, however, Leeks generally are a most useful crop from mid-winter onwards, and especially in severe weather. They ought, therefore, to be cultivated extensively. Market gardeners near Welsh seaports grow them largely for supplying the ships. Than Leeks I have been told no crop pays better, and I do not know of any winter vegetable which gives such a long supply as a good bed of Leeks. They never shrink by frost, and when well cooked they may be set before a prince.—CAMBRIAN.

SHORT NOTES.—KITCHEN.

Kitchen garden seeds.—We hope our correspondents will not send us any more articles on the selection of seeds for the kitchen garden. We observe that some of those that we receive are lists of mainly newish things, and exclude some of the best old standard vegetables.

White Elephant Potato.—I find that this seems to give me the most delicately flavoured Potato of all the kinds that I grow, and it has good qualities in other respects. Generally the effect of my soil on Potatoes is so bad, that I do not care to eat them. Have others of your readers noticed the same merits in this Potato?—G.

KITCHEN GARDEN NOTES.

GLOBE ARTICHOKEs.—Twenty degrees of frost, twice in succession, and many nights 12° and 11°, combined with repeated successions of thaw and frost, the protecting leaves notwithstanding, have been too much for our plot of Artichokes. They are so injured, that they might as well be killed outright; and having made up our mind to this, a sowing has just been made in deep boxes, which in due course will be potted singly and grown on in a warm pit, and gradually inured to bear full exposure by planting-out time early in April. Meantime the old plantation will be heavily manured and deeply trenched in readiness for the seedling plants. A deep, moist soil—or, lacking the moisture or holding property of the soil, a half-shaly position, with plenty of depth of soil—is essential to the obtaining of large, succulent heads. The next requisite is plenty of space for free development of growth, 5 feet being none too great between the rows, and not less than a yard apart in the rows. The 5 feet may to some appear excessive, but in good soil during the second year of growth the foliage of the plants will fill out that space, and the first year the ground between the rows can be utilised for a catch crop of Cauliflower, Lettuce, Spinach, Radish, or dwarf French Beans. Of course, if there is plenty of ground for keeping up a full supply of the various kinds of vegetables without having recourse to double cropping, so much the better for the Artichokes, for then a full amount of manurial mulching can be given; and this, with waterings over it in dry weather, will by the end of the summer and all through the early autumn months result in a good crop of medium-sized heads of the finest quality; and next year, if well guarded from severe frost with plenty of leaves, long dry litter, or Bracken, the produce of the plants will be at high-water mark. Three, or at most four, years are the longest period that the plants should remain. Perhaps the simplest, but in prospect of such winters as the one we are passing through, by no means the surest way of keeping up successional relays of plants, is to sow in drills in well-prepared ground about the middle of March, and thin out the seedlings to about 18 inches apart, transplanting to permanent positions any time during the month of February in the following year, and treating liberally in respect to rich top-dressings. Repeat the plan year after year, and, as a matter of course, destroy a proportionate number of the old stools that have borne for three or four years. To obtain handsome and extra-sized heads, it is necessary that all weaklings—hard, wiry stems—be cut away, and the small branchlet heads—what I call gills—that sometimes form on the strongest stems immediately under the large heads should be rubbed off as soon as perceived, for they are not only great robbers of the finer heads, but even when full grown they are useless, because so small.

CABBAGE.—Cabbage plants will be scarce this spring, and they will be in great demand, as many are killed, and there are many blanks in the autumn-planted plots; and, worse still, the sprouts from the old plantations that can generally be relied on to afford ample supplies of greens till the autumn planted are fit for use, are quite done for, and in prospect of such scarcity we think it advisable to sow at once in pans or boxes, and put them in a dry airy frame to germinate, bringing them up as sturdily as possible by airing freely, and pricking out in cold frames as soon as may be. With careful treatment in respect to the avoidance of a check in growth, and when ready to plant to lift them with the soil adhering to them, the probability is that they would be ready for use quite as early as the autumn planted. The earliest varieties should be selected for this sowing, of which Reading All Heart and Ellam's Early are two of the best that have come under my observation. We shall make a sowing of these kinds on a warm border in the open air, as well as in frames as soon as the soil is workable. Cabbage of every description to be of high quality must have deep tilth and abundance of manure. As to texture of soil, light, heavy, or medium

suits it, provided there is plenty to feed on. To poverty of soil and successive cropping of the same ground with Cabbage of some description or other is entirely due that worst of all pests to Cabbage culture, viz., "clubbing." Moral: avoid the same and be even as I—, never bothered with it. All early varieties of Cabbage are small, and may, therefore, be planted closely together. As a general rule we allow them a distance of about 10 inches in the row, and draw out alternate plants for use, as Coleworts, which leaves 20 inches for the growth of the remainder, and there is a space of 2 feet between the rows, which we find sufficient to get about comfortably on the plots to move the soil for the destruction of weeds, and, if needs be, which is sometimes necessary to keep the plants firm, to draw soil to the stems of the plants. It is only for the sake of securing the plants in position that we care to earth up at all, for there really is no other merit attached to the process.

FORCING ASPARAGUS.—I suppose that this is a favourite vegetable with everybody. It is greatly appreciated here, but supplies are never asked for till February, because we consider that it is never of high quality till there is sufficient daylight to well green the tops. A terribly heterodox notion this I know with the "blanchites," who apparently prefer insipidity to sweetness. We force it in frames placed over ordinary hotbeds of leaves principally, and a little long litter added, which has the property of starting the heat of the leaves into rapid motion. Soon as the frames have been put on, about 6 inches of roughish vegetable mould is placed over the beds, and on this the plants are packed closely together, the roots being spread out flat-wise; then another 6 inches of the same mould buries the plants from sight. A good watering with tepid water is at once given, and in from a fortnight to three weeks a supply can be had. It is necessary to guard against the heat of the beds getting too violent. This can only occur from the too free use of litter with the leaves, as the latter never overheat of themselves, unless the bulk necessary—about 4 feet—be greatly exceeded. To keep a constant supply till it can be had from the open ground—about the middle of April—we find it necessary to put in successional batches once a fortnight. Strong plants continue bearing for about three weeks, and this period can be somewhat extended if, as soon as the plants seem to languish, a thorough drenching with tepid manure water be given and the linings round the sides of frames be renewed.

PEAS AND BROAD BEANS.—Our first sowing in the open ground of both these will be made this week: the former on the best sheltered border we have: the warmest is, of course, reserved for the Peas that were sown in pots three weeks since. Broad Beans are given more open quarters, though, for the sake of earliness, the most sunny spot that can be spared, and for once they are favoured with a bit of our very best ground, more by chance than election, though. It happens in this wise. Our winter Spinach being a failure, we must have this vegetable at the earliest possible date; hence the fine sunny spot and good ground that the Beans are destined to share with the Spinach. They will be planted in a double triangular line 6 inches from seed to seed and 4½ feet between the rows, and midway between them will be sown a row of Spinach, which crop will be off before the Beans are full grown, when they will take up the entire space. I care for no other variety than the ordinary Long-pod for this early sowing, and for late supplies none excel the Broad Windsor.

HORSE RADISH.—"Mistakes in gardening" would be a fine subject for an essay of interminable length for anyone who felt disposed to begin the work of reforming the same, and who believed that long winded effusions in the gardening papers would start the ball rolling in that direction. I, for one, do not think that plan half so good as tackling the mistakes one at a time, and showing, by what has been done, the way to avoid mistakes in future. But, it may be asked, what has that to

do with Horse Radish? Why, just this much: that no other kitchen garden edible receives such unfair treatment; and it is a mistake, as the plant is as amenable and as profitable to generous cultivation as is the most valued vegetable of the garden. As a rule, any out-of-the-way corner and any kind of soil are considered good enough for this, and such being the case, can the roots be expected to be aught else but small, dry, and shrivelled? Granted that Horse Radish plots look for the most part of the year nearly allied to weed crops, that is no justification for neglect as to growing it well, though it may be for keeping it out of the most conspicuous parts of the garden, a far different matter that from giving it any sunless spot under the shade of trees, and of manure, none. We are able to boast that such is not our plan. We are now trenching up part of the old bed, some four years planted, and all the roots, small and great, are picked out as the work proceeds: the stout sticks are heeled in for present use, the medium-sized are reserved for planting, and the smallest rootlets are thrown away. The ground is being trenched three spits deep, and a good layer of manure is put in immediately over the surface soil, and the trench filled up without adding another layer of manure, which would conduce to the production of side or lateral rootlets, that are ever to be discouraged. In the meantime the medium roots will be prepared for planting by being cut into from 6-inch to 8-inch lengths, and all the eyes, except one or a couple at top, be rubbed out in order to prevent the growth of the thong-like or forked rootlets just mentioned. We plant with long dibbers in lines 2 feet apart, and a foot apart in the row, the top of the stem being pushed a couple of inches beneath the surface of the ground, and this completes the process. By this mode of cultivation, sticks half as thick as one's wrist can be had in twelve months' time; in fact, by the autumn of this year the produce will be far above the average of that from the "as-you-were" style that continues in vogue in many gardens.

TREES AND SHRUBS.

W. GOLDRING.

THE AROLLA, OR SWISS STONE PINE.

(PINUS CEMBRA.)

THE Arolla is as conspicuous in Swiss scenery as the true Stone Pine (*Pinus Pinea*) is in an Italian landscape. It is the prevailing tree throughout the Swiss Alps, where it forms dense forests in the valleys and clothes the mountains up to a higher elevation than any other coniferous tree. It has been found at heights of 6000 feet, but, though it is the prevailing tree of Switzerland, it is indigenous to various other parts of Central Europe, and extends across the Carpathian and Ural Mountains to Siberia, where it is again the

Coning branch of *P. Cembra*.

predominant tree in the forest regions. It has, therefore, a very wide geographical range, and in every country where it grows wild it is a most valuable tree—valuable for its timber, and not unimportant in the way of affording an article of food. As a cultivated tree this sturdy mountaineer is also most useful in ornamental planting. Being different in shape and in colour from its associates, it is capable of adding effect to a tree group such as no other Evergreen could do. Its

peculiarities are its heavy masses of very deep bluish green foliage, and its erect conical growth, so compact and dense as to render it discernible at a glance among crowds of other Pines.

There is a considerable diversity of opinion

Seedling of *P. Cembra*, showing the numerous seed leaves.

among writers upon Conifers respecting the merits of the Arolla as an ornamental tree. Some consider that it is too gloomy and monotonous in appearance. That was London's opinion. Lambert, than whom no one knew Pines better, considers it one of the handsomest in the genus, and that is my opinion. It is a beautiful little tree, hardier than any other Pine, and one which never refuses to grow and thrive in any situation, however cold, or in any soil, however poor. Such a tree, therefore, is worth attention, and by planting it well at the outset and by placing it well so that it may borrow additional beauty from other trees in its neighbourhood, it would for generations form a striking feature in any garden or park. Some object to it on account of its very slow growth, but as it is known to be slow, no one would think of planting it in a place where a tall tree should be. On an average it grows about 9 inches in a year, according to the soil and locality in which it is placed. In Scotland, where the climate is more akin to that of its native mountains than that of England, it grows faster, especially if in good free soil. The best soil for it appears to be a deep sandy loam, but no one need go to much trouble in the matter of soil for the Arolla, as it grows in any material from peat-bog to dry sand. As regards the planting of it, so that its fullest effect may be obtained, my opinion is that it never looks so well as when you see a group of it, consisting of, say, about six or eight trees planted irregularly and of different heights, the tallest overtopping the smallest by about half its height. Such a group as this one may see any day in the Kew arboretum. When a tree is large and fully clothed to the best so as to make what is called a fine specimen, as one sees at Dropmore, then

an isolated tree has a fine effect. This Pine, associated with any other Evergreen, always has a telling effect, especially in winter; but one should be careful in mixing it solely with deciduous things, as in winter its darkness may produce a spotty effect.

The Cembra Pine belongs to that group of species which have five leaves or needles in a sheath. The leaves are 2 inches to 3 inches long, deep green above, lined with silvery white beneath, and this silvery line is so marked in some trees, that it shows distinctly at a distance. The cones are well represented in the accompanying woodcuts; the large one is full-sized, and the small coning branch shows how the cones are borne erect on the branches. The seeds are wingless, and, compared with those of other Pines, are very large. The seed is enclosed in a very hard, bony shell, so hard indeed, that it is with difficulty broken. The seeds are eatable, being very oily and pleasant to the taste, and like the seeds of the Italian Stone Pine, are eaten by the poorer Swiss in winter. For squirrels and other seed-eating creatures they are dainty food, and it is interesting to see how dextrous the squirrel is in extracting the dainty morsel from its bony covering. In the Kew museums there are the actual cones of the Arolla that had been half-devoured by squirrels, and one can see how cunningly they manage to get out the kernels with the least amount of labour. The cones take a year and a half to grow full-sized; that is, the catkins are produced in early summer, and the cones ripen in November of the following year. In a young state they are of a rich violet-purple colour, the colour of a ripe Orleans Plum, as one writer puts it; and seen nestling amongst the foliage they have a pretty appearance.

P. Cembra. Full sized cone, leaves, cone scales and seed.

P. Cembra is a very old tree in this country, having been introduced by the Duke of Argyll, or the tree-monger, as he was called, who first

planted it at his place at Whitton, in Middlesex, in 1746. Afterwards it was much planted about the country, and so plentifully was it planted at Gledhow, in Yorkshire, that it went by the name of the Gledhow Pine. Perhaps some reader could say if any of these trees at Gledhow are still growing there. At Walcot, in Shropshire, it was also largely planted by the late Lord Clive, and thirty years ago the largest of the Walcot trees were from 40 feet to 50 feet high. But it is more for ornament than utility that it has been planted in this country, although many have advocated the planting of it as a timber tree in hilly districts. Its wood is excellent, being very workable, of a pleasant light brown colour, with scarcely any grain, and, moreover, agreeably fragrant. The quaint wooden figures sold in Swiss shops are mostly carved from wood of this Pine. An excellent idea of the aspect of the Swiss Stone Pine as it appears on the Swiss Alps may be derived from the illustration given in THE GARDEN, Vol. XXVIII., which was re-

slow in growth, it is true, during the first few years from cuttings, but when old they remain as they are, and never require clipping, pruning, or cultivating in any form.

The Golden Scotch Fir.—It is stated in THE GARDEN, January 8, with reference to this tree, that "it may not be so rapid in growth as the green, and it will be years before a big tree can be seen of it." Now, neither of these assertions should be accepted as an *ipso facto*, for twelve years ago I saw in a mixed Larch, Scotch, and Spruce Fir wood on Churchhill estate in Ireland a tree of the Golden Scotch Fir that was then fully 16 feet in height, and had kept pace as regards rate of growth with its surrounding neighbours. Since that time I have not seen the tree, although I have had specimens of the foliage sent me for scientific purposes, but if now standing, and I have good reasons for believing it to be so, it must be considerably over 30 feet in height. The variegation was constant and beautiful, not wanting in summer and reappearing again in winter, as your correspondent states is the case with this tree, and evenly spread over all the foliage. It was a chance seedling, and was not detected until the plantation in which it was growing had attained to a considerable height. The Golden Scotch Fir is beyond doubt the most ornamental Conifer we have, the deep bluish green of the normal foliage offering such a marked and pretty contrast to the rich golden of the variegated leaves. This was strikingly exemplified in the specimen above alluded to, and which, growing side by side with the normal green-leaved plant, brought the different colours of foliage into bold relief, and as the tree was growing within easy distance of the road, curiosity tempted many a passer-by to halt and examine so beautiful, distinct, and imposing a plant. An Edinburgh nurseryman to whom my father pointed out the tree was simply electrified with its appearance, and would willingly have undertaken the rather arduous task of transferring it to a conspicuous spot in the Scotch metropolis. I wish the commonly accepted opinion that both the golden and silver-leaved forms of the Scotch Fir revert to the normal colour in a year or two would receive less credence, but it is not likely to, for late authors on Coniferae simply perpetuate the mistake.—W.

Spiræa Douglasi.—Where, as is the case in most home nurseries, there is excess of certain plants over and above the demand, it sometimes becomes a matter of consideration how to profitably dispose of surplus stock, and such is usually the case with rapidly increasing shrubs like the one above referred to. To avoid waste experiments with such plants for other purposes than those they are usually applied to is the rule in most nurseries, and it, therefore, will not perhaps sound so strange when I recommend the present *Spiræa* as a valuable hedge or covert plant, and one that is well worthy the attention of persons who, at the present season, have the formation of such on hand. Amongst the shrubby species of *Spiræa* no other, in my opinion, is so well suited for extensive park planting as *S. Douglasi*, it having at least half-a-dozen of the best recommendations that could be linked to any plant. It is perfectly hardy, of free growth, and increases rapidly from the root, is not fastidious about soil, situation, or shade, forms a dense, well-shaped bush, and is, when in full flower, one of the most ornamental shrubs that can be imagined. The flowers, which are of a bright pink—but there is a lighter-coloured form—are arranged in dense, terminal panicles, of from 6 inches to fully 10 inches in length, and are borne in great abundance. A hedge of this plant during the flowering season is pretty almost beyond description, and the flowers, being of good substance, last well, and remain during fine weather in exemplary condition for a long period of time. For planting in masses in conspicuous places, this *Spiræa* is especially valuable, and it is not required to plant thickly, for if the soil be only of average quality, the roots soon wander about and fill up with their many and strong shoots the

intervening spaces between the plants, thus rendering the shrub a much-to-be desired one for using in game preserves or wherever a dense, twiggy undergrowth is desired.—D.

The Winged Elm (*Ulmus alata*).—By far the most conspicuous tree in our deciduous woodlands at present is the Winged Elm, a fact that I could not help noticing some days ago when passing along a private road, one of the sides of which was lined with fair-sized specimens of this useful tree. What renders it so distinct from Elms in general is the peculiar corky excrescence with which either side of the branches, big and small, is furnished, thus imparting to the whole tree, when destitute of leaves, a gouty appearance, or rather as if the branches were of inordinate dimensions, but which, on closer inspection, is found to be caused by the corky winged ridges of the bark. On examining some of the smaller branches this ridge of bark is found to be quite as deep as the diameter of the tree on which it is growing, and as there is the same excrescence on either side, the whole appearance of the branch is increased to fully twice its real size. Here the Winged Elm has attained to a height of fully 40 feet with a trunk circumference at a yard up of 4 feet 7 inches, dimensions that are rarely exceeded by the tree, even in its native American wilds. The leaves are small, serrated, and resemble in no small degree those of a vigorous growing young Hornbeam tree. Being of easy culture, perfectly hardy, and an interesting species that imparts an unusual appearance to our woods in winter, the Winged Elm is worthy the attention of planters, and, being obtainable at a moderate cost, may be used freely enough along the outskirts of such woods as border roadsides and drives. In thinning the wood in which these trees occur in some plenty it was found that the timber was hard and firm, redder in colour than that of either the Scotch or English Elm, and more difficult to cut with the axe. As regards lasting qualities of the wood, I cannot speak with any amount of certainty, for the trees cut down were not deemed of sufficient size, nor were they so fully matured as to form a just idea of the wood when full grown and ripe. The soil composing the wood in which they thrive best here is light loam resting on deep gravel.—A.

The Colchic Laurel.—This is a finer, a more genteel plant than the common form, one that has been found to be perfectly hardy in this country, and almost proof against the attacks of game. Where a large, strong growing plant for screen purposes is wanted, by all means use the common Laurel, but where a refined appearance, a dense dwarf growth, and a non-troublesome plant—at least, so far as pruning is concerned—is of paramount importance, give the Colchic form preference. The leaves of this latter plant are of a pale green colour, fine in texture when compared with the common form, slightly serrated, and remarkably smooth of surface, in this latter approaching very near to those of the Rhododendron. We have used it rather extensively for some years past, and find it a very desirable and useful estate plant, it coming in well for shrubbery formation, for clothing of banks with a procumbent evergreen growth, and in the making or renewing of game preserves. The "catalogue" statement that the Colchic Laurel is proof against the attacks of ground game is rather "stretched," and it might, perhaps, have been better to say that it is almost so, or less liable to get nibbled and barked than the commonly cultivated plant. It is of slow growth compared with the latter, but spreads horizontally to a greater extent, and bears pruning as well as any covert plant I know of. Cuttings inserted in the usual way produce roots quite freely, and the young plants soon gain strength and vigour, and become dense bushes by the third or fourth year, at which period they are fitted for planting out permanently. I do not think that the Colchic Laurel is by any means fastidious about soil, for here it is growing in dry and damp, stiff and free, loamy and peaty, and with but little appreciable difference. As to situation, it is likewise totally indifferent, for a break planted with

An old tree of *P. Cembra*.

produced from a photograph sent by Mr. Otto Forster. The spot illustrated is in the Zemmergrund Tyrol, where Mr. Forster says one rarely sees a specimen tree, all being weather-beaten, old, rugged, and most picturesque. He says that the largest tree in this region does not exceed 80 feet high, and one with a diameter of 6 feet is probably a thousand years old.

Tree Ivies.—There is not half enough use made of Tree Ivies; one may go into a dozen gardens and not see one. Their special value is for planting for winter effect, for then, on account of being different from every other Evergreen, they are the more noticeable. They are infinitely better for winter beds than small Conifers or other things usually planted in them, because they never grow too large, are always tidy looking, and their hardiness is never questioned. Specimen Tree Ivies about a yard high and as much through are as handsome Evergreens as one could have in prominent positions on a lawn, and especially if planted so as to form an irregular group rising from a groundwork of creeping Ivy. Tree Ivies are, of course, nothing more than the common Ivy, tree-like instead of creeping, and now we have them of various sorts, some golden-leaved, others gold and silver edged, so that one can vary their effect. They are

these in our home nursery and with a northern aspect are just as healthy and vigorous in growth as those planted under what would be considered more advantageous circumstances.—A. D. WEBSTER.

Cryptomeria elegans in winter.—One or two specimens of this Conifer planted about a lawn are capable of producing a colour-effect such as no other tree can, and for that reason it has a peculiar value. Just now every tree of it glows with a reddish coppery hue, which it begins to put on as early as August, intensifying every month until in mid-winter the colour is very rich. It afterwards gradually loses the coppery hue, and by about April the foliage has quite reverted to its original green. If associated with the darkest Evergreens, the coppery hue is intensified, but the *Cryptomeria* should be made to stand out with the green as a background. The elegant feathery growth of the tree, with the branches always drooping, gives it a different aspect from other Conifers, and it is not so rigidly formal in outline as most others. It is a hardy, free growing tree, not particular as to soil, rarely refuses to thrive in any conditions, but of course growing best in a good, free soil and a sheltered spot. There is a dwarf variety of it (*nana*) which is useful to plant in certain spots where the other would be too big.

The golden-leaved Chestnut is a neat little evergreen bush that many would like to have in their gardens. It is so unlike its relative, the common Sweet Chestnut, that there is no comparison between the two. *Castanea chrysophylla* is a native of California, in parts of which State it forms a dense undergrowth of from 4 feet to 6 feet high, and is often found in company with the Monterey Pine (*Pinus insignis*), but in other States, Oregon, for instance, it grows to a height of 30 feet. As we know it in European gardens it is rarely more than a dwarf, dense bush, having leaves somewhat similar to those of the Bay, but smaller. They are deep green above, while the under-surfaces are covered with a golden tint, hence the name *chrysophylla*. It is perfectly hardy, never affected by our hardest winters, and may be grown perfectly well in Scotland—indeed, some of the best plants of it exist in and about Edinburgh. The largest cultivated specimen is supposed to be that at Totterworth Court, in Gloucestershire, and has been planted nearly thirty years. Even when only 2 feet or 3 feet in height, this Chestnut produces fruit freely, and these are miniatures of the spiny Sweet Chestnut fruits. In bold rock gardens or in masses of dwarf shrubs are the places in which to plant this shrub. It thrives best in a deep moist loam.

Abies brachyphylla.—No one need hesitate to plant this Japanese Silver Fir, which may still be called new, seeing that it was only introduced in 1870. In the "Manual of Conifere" it is described as "one of the hardiest and handsomest of the Silver Firs," and a truer description could not be given of it. Every year it seems to improve, although the largest plants in this country are scarcely beyond the nursery or sapling stage. It is likely to outgrow all the other Silver Firs, not even excepting *A. Nordmanniana*, which bears such a high reputation among tree planters. The young trees I have seen of it in the various English nurseries and gardens all indicate a sturdy and robust growth. The stem grows perfectly erect, and is rarely seen without a good leader. The branches spring at regular intervals, so as to form a symmetrical cone-like tree. The leaves are short (as the specific name implies), and almost as dark a green as in *Nordmann's* Fir, but instead of lying in two flat rows on the branches, they are more irregular, thus giving the tree a different appearance. Every specimen I have seen was feathered to the ground with branches, and the bottommost did not show any signs of losing foliage, as so many of the other Firs do. There is no doubt but that we have in *A. brachyphylla* a valuable tree for ornamental planting, if not, indeed, for timber. It is said to grow in Japan and Saghalien (it being a native of both islands) to a height of 120 feet. In Veitch's "Manual" it is stated that this Fir stands the Danish winter uninjured.—W. G.

Malus Halleana. In answer to "G." (p. 83), I may say that the origin of this is unknown to me, but it has much the habit of *Malus floribunda*, from

which it differs in the leaves being narrower; the leaf-stalks are more flushed with red and the flowers deeper in colour, thereby rendering it more conspicuous than even that well-known and much-appreciated shrub. My plants were obtained from Messrs. Transon, of Orleans, in France, who describe it as "a new distinct Japanese sort with narrow leaves and pink flowers." Such a handsome shrub will, no doubt, soon be grown by our English nurserymen.—A. P.

Gordonia pubescens.—This very beautiful shrub or small tree I have grown for many years. With me it grows vigorously in a deep alluvial soil, which is rather moist, but not wet, and it flowers fully three months, i. e., during July, August, and September. It is a native of our Southern States, and this is about its northern limit where it can be grown. The flowers, which are large, are of the purest white, and produced in great profusion. In England I should say this plant would succeed in the American border, but it should have a warm position. What English cultivators should aim at with all our shrubs and trees, especially from the Southern States, is to get the wood thoroughly matured. There is no degree of cold experienced in England greater than that which they will withstand in this latitude, where we have the thermometer frequently 10° below zero, and I have known it much lower than that without plants being injured in the least. The *Maclura*, a southern tree, fully illustrates this; young plants of it in England grow with great vigour, and the young growth is killed back in winter. Though a southern tree, this stands well in the Northern States and ripens its wood to the tips. Thus, where matured, even a temperature of 20° below zero does not injure it. Cultivators may take it, as a rule, that all the trees, shrubs, and plants of North America are hardy in Great Britain—that is, they will endure the lowest temperature known there, provided their wood is well matured.—JOHN SAUL, Washington.

Magnolia Halleana—"W." (p. 84) speaks of this *Magnolia* as though it has not been distributed, but surely a thoroughly hardy bush which has been for some years recommended by nurserymen must by this time be fairly well known. If it is not, permit me to inform all lovers of good things that they should lose no time in securing plants of it, as I believe it will be found to be perfectly hardy in the shrubbery border, and being so dwarf, so compact and complete in all its parts, and so early, the day should not be far distant when it will form a new feature in the foreing house and greenhouse. By far the finest collection of hardy *Magnolias* I have met with is in the grounds at Hatfield, the seat of Dr. Henry, near this place. They were planted most likely by the late Donald Beaton, who lived there when a young man, and occupying as they do a warm sandstone bank, sloping to the south, backed and flanked by grand Conifers, they are worth a day's journey to see. There, striving, and not in vain, with *Abies Douglasi*, the stately *M. acuminata* has formed a splendid tree, the smaller varieties including *M. conspicua*, *M. Soulangeana*, *M. glauca*, and others graduating down to the margin of the lawn. *M. Halleana*, if not already planted, will, I have no doubt, soon complete this fine group, of which the owner is so justly proud. When I state that Mr. Gordon, Mr. Beaton's employer, and a great experimentalist, succeeded in fruiting the Japanese Medlar or Loquat against a wall within a few hundred feet of the *Magnolias*, your readers will gather that the situation is exceptionally favourable; but this fact need not deter them from planting any of the deciduous varieties and species, as all will grow and produce their lovely foliage if they do not flower so freely in much colder places.—W. COLEMAN.

SHORT NOTES.—TREES AND SHRUBS.

Choisya ternata.—This has suffered a good deal this winter from the cold; where planted in the open in various gardens about London it has been sadly injured, and even against one of the walls at Kew a large bush of it has the tips of the shoots killed. It is not a reliable hardy shrub about London and north of it.—G.

Butcher's Broom under trees.—In many instances the ground under trees is bare and unsightly, and an idea prevails that it is impossible to get anything to grow in such a position; but that is a mistake, as there are several plants which grow under the shade and drip of trees, and amongst these *Butcher's Broom* may be placed at the top. It grows wild in the lower parts of Glamorganshire, and I know of many cases in Wales in which it forms a dark verdant mass under dense shade; indeed, I never knew it to fail under trees; it not only exists under such conditions, but grows rapidly, and, although it may not become very tall, it spreads out freely. I can therefore confidently recommend it to all who require a plant that will succeed admirably under trees.—J. MUIR, *Margam, Port Talbot*.

The Laurel-leaved Phillyrea (*P. Vilmoriniana*).—This is unquestionably the best hardy evergreen shrub that has been introduced to this country of late years. After the severe weather we have had, which nipped Laurels and other hardy shrubs, this *Phillyrea* bears no trace of injury; there is not a leaf browned or spotted, and this extreme hardness, combined with its rapid growth, neat habit, and handsome foliage, makes it an invaluable winter shrub. It is a good deal like a narrow-leaved Laurel, hence the name *laurifolia*, by which it is known in some nurseries and gardens, and on account of its neat growth it has been also named *decora*; but *P. Vilmoriniana* is the name the botanist Boissier gave it in his "Flora Orientalis." It is said to grow as high as 10 feet, but the specimens at Kew are not more than 4 feet. The leaves are thick, leathery, of a deep shining green, and in shape like those of the Caucasian Laurel. It bears a profusion of small, sweet-scented flowers in May, which are succeeded by small black fruits in autumn. But the flowers and fruit are not worth taking into account; its value lies in its foliage, and it is not too much to predict that it will in time prove to be one of the very best of Evergreens. It is already grown in tree nurseries, where its value is recognised, and it is being largely propagated. It is a native of the mountain region of the Caucasus.

The winter in South Wales.—This has been so far the most severe winter experienced in South Wales for these last ten years at least. In previous winters the thermometer has been lower at times, but we have not had so long a continuance of frost and snow as we have experienced lately. We have had frost almost weekly since the end of October; snow has fallen often, and the weather has been altogether most wintry. At present we have a keen black frost, with a piercing north east wind, and vegetation has a very sickly appearance. Wind always does more harm than a still frost, and I am greatly afraid that many of our trees and shrubs have been injured. We had quite a hurricane in November which scorched every Evergreen with which it came in contact. Pines are browned more than ever I have seen them, and evergreen bushes, such as Laurels, *Arbutus*, Sweet Bays, *Rhododendrons*, *Laurustinus*, &c., are quite scorched. Had the storm come earlier and caught the wood before it was matured it would have been much more serious; as it is, I believe that many of the younger growths will die back. In such cases it is a good plan to defer cutting back or pruning very much until it is seen what wood has perished. The different varieties of *Euonymus*, which I have often recommended as being specially hardy, are the only bushes which have withstood the weather without blemish. These pretty Evergreens cannot be too extensively used in exposed places or in ungenial atmospheres.—J. MUIR, *Port Talbot, S. Wales*.

January flowers.—Owing to snow-falls, frost, and a continued low temperature, we have had fewer January flowers than usual. Amongst shrubs, *Chimonanthus fragrans* and *Jasminum nudiflorum* have blossomed as usual; the last named less freely than in previous years. But *Garrya elliptica* is so far quite destitute of flowers. The first Snowdrop opened on the 24th, and a solitary *Primrose* may be found in warm nooks, but the winter *Acquite* is conspicuous by its absence. *Tussilago fragrans* has been fairly plentiful. *Erica carnea*, which in some seasons begins to show a little colour at the end of January, is still wanting

its winter garb. Altogether, the number of out-of-door flowers is few for the west of England at the time of year.
J. C. C.

FLOWER GARDEN.

BRUGMANSIAS OUT OF DOORS.

WE use both the double white Brugmansia and also the single one in the sub-tropical garden in summer, and in a hot, dry season here in the south they do admirably. The double variety with us blooms much the most freely, and in the evening the perfume from its blossoms scents the whole neighbourhood in which it is growing, but during the day there is not much scent emitted by it. The single variety is more delicate in perfume, and it is emitted throughout the day as well as during the night. When planted in the beds, which they should not be before the first week in June, an open spot sheltered from the south-west and east winds should be selected for them, but they should have abundance of sunlight. With the ordinary soil in the bed work in some partly decayed manure, and if at all dry after planting and during the following months water copiously both at the roots and overhead in the evening after a hot day. If this be neglected and the plants are allowed to become dry at the roots, the leaves soon assume a sickly hue and become attacked by red spider, which quickly checks free growth and spoils the blooms. Free growth without being too luxuriant is what is required, and in order that both foliage and flowers may be developed in the best possible manner an occasional dose of liquid manure may be given. Early in October and before any signs of frost have appeared they should be lifted; having previously cut around the roots with a spade, place them in pots sufficiently large to hold their roots and some soil. Place them in a cool vinery, and if under a Vine all the better, as the shade of its leaves will prevent them from flagging too much. Syringe them overhead at times in order to assist them to start afresh, when they will throw out blossoms and continue to bloom up to and sometimes after Christmas, such flowers being very sweet particularly at that season both on the plant or in a cut state. After blooming is over gradually withhold water from the roots, and keep the plants in a cool house free from frost. In spring, just before growth commences if the plants are getting too large, prune the shoots in freely; young growths will start from below the places to which they have been cut back, and by planting-out time in summer the plants will be in good condition for that purpose. Another way in which they can be wintered is to pack them away, placing soil around the roots, in a cool house under the stage and keep them rather dry during winter. In such a position they may stay until the time has arrived for planting them out again in the beds. The quickest way in which to increase the stock is to take off the young shoots or offsets which sometimes spring from the base of young plants with roots attached to them. Pot and keep them close for a time and they will quickly make nice plants. Pieces of half-ripened shoots, too, inserted singly in small pots in spring and plunged in a brisk bottom heat soon emit roots, and if potted on and kept growing in a temperature of about 60° they soon make good plants, which, if kept in pots during the summer, will often bloom the following spring and be useful for the ornamentation of rooms. When three or four years old they get leggy, and are then used for flower beds. The latter may be carpeted with *Sedum glaucum*, dotted here and there with *Perilla* or *Iresine Lindenii* or some other dwarf dark-coloured plant. The Brugmansias should be planted singly in small beds, or at considerable distances apart in larger beds where they can have free development for both flowers and foliage. Thus treated they are far more satisfactory than when huddled closely together, where neither the beauty of their leaves nor flowers can be seen to advantage. When planted closely, too, the growths

made are weak and spindly, and the flowers produced are in consequence few and poor in quality.
E. M.

White Trumpet Daffodils.—I have read carefully and with interest all the correspondence that has taken place on this subject, and as Mr. Burbidge has suggested that I might give my opinion in reference to Chiswick as a trial ground, I will try to do so. I must confess, however, that I have not succeeded so well with the white varieties of Daffodils as I have done with the other varieties, but my soil is not the Chiswick soil, and I can see no reason why white Daffodils should not do well there. The fact remains, however, that there is a feeling against Chiswick as a trial ground, for, although bulbs were promised and growers were all invited to send them there, not one bulb arrived at the trial ground last autumn. Such is the difficulty with which the Daffodil committee has to deal. Though I have said I see no reason why white Daffodils should not do well at Chiswick, yet if I were asked if I would prefer Kew to Chiswick, I would say, "Yes." The soil at Kew is light, and there is no fear of stagnant water; there is also there any amount of tree roots, and no lack of skill to manage the bulbs. I feel sure, too, that the Kew folks would find a situation suitable for the trial if contributors would indicate the sort of tree roots with which the bulbs love to be associated. In their various stages of growth they could be seen by the whole staff; and, therefore, no sub-committee would be required. Some may say we could not claim a report from Kew, but I believe, nevertheless, that a report would be forthcoming when required. Let us hope that the committee, when it meets this spring, will be able to decide this matter. J. WALKER.

Helleborus altifolius.—With reference to the discussion about this plant now carried on in THE GARDEN, allow me to state that *H. niger* inhabits the northern, and *H. altifolius* the southern declivities of the Austrian Alps. The line of demarcation of their respective areas is very well defined, and they do not mix with each other. I am of opinion that Mr. Engleheart's plant is the true *altifolius*, and if it does not agree with the *altifolius* of English gardens, I am not at all surprised, because *H. altifolius* of English gardens is, horticulturally at least, a very different plant from the true *altifolius*. The English plant appears to have changed its original character in a very marked way; by what may be called cultural evolution it has become a stout, early-flowering plant, whilst the type is slender, and has—prevented by snow and ice from starting early—retained its natural habit of flowering in March, while the *altifolius* of English gardens is now at its best. Typical *altifolius* has not a cup shaped, but rather a flattish flower of a very pleasing tint, viz., a pinkish or rosy white, more or less, even if kept under glass. I wonder why any value is placed on a pink or green stigma, which is only produced by climatal influence, especially by often changing temperatures, which cause the flowers to become moist and dry alternately, according to circumstances. If it would be worth while, and I had time to spare, I would engage to produce *niger* with pink stamens, and *altifolius* of English gardens with green ones. I was glad to observe attention directed in THE GARDEN to *H. niger* *præcox*, which, though its flowers are small, is valuable on account of its flowering early. A big plant of it here began to blossom about the middle of October, and there are still some flowers on it; the smallness of the blooms we shall soon change, by raising seedlings upon seedlings, which, if treated rationally, flower the very first year after germination.—MAX LEICHTLIN, *Bahen-Bahen*.

Effects of the late snowstorm.—On looking round Oakwood garden to see what damage had been done by the late snowstorm, I found that we had escaped more easily than could have been expected. Some time back I recommended a fence made of rabbit wire, 6 feet high in one piece; we have a quantity of this which is sufficiently supported for any ordinary strain, but

above 70 yards was blown over, the snow having filled the meshes and so given the wind purchase; therefore it seems desirable, when this fence is used, to add to the supports by wires fastened to any trees on the line. Our large *Camellia* has only one or two small branches broken, but my man beat much of the snow off. A fine head of *Andromeda japonica*, covered with buds, was broken off, and a large *Choisya ternata* had some branches broken, but a large *Photinia serrulata* close by is uninjured. Our big *Rhododendrons* in the wood have hardly any branches broken; *Meconopsis Walliichi*, unprotected, looks perfectly fresh and green; seedlings of *Sikkim Rhododendron*, not above an inch high, do not seem to have felt the cold; *Ilex latifolius* is very little touched. The effect of the snow was shown along the road to the garden by the great numbers of branches on the ground at the edge of the Fir woods. A friend with a beautiful garden at Chiselhurst gave a most saddening account of breakages of a great number of his trees and shrubs. So far our coops, with Braeken interlaced, seem efficacious as protection for tender plants. GEORGE F. WILSON, *Heatherbank, Weybridge Heath*.

Mr. Wm. Goldring, long on the staff of THE GARDEN, who has for some time paid some attention to landscape-gardening, now proposes to devote himself to it as a profession. Landscape-gardening hitherto has always suffered from a want of knowledge of our rich stores of plants and trees on the part of its professors, so that they have been tempted too often to fall back on the absurd or the bizarre in lieu of what a lover of Nature would expect in a garden in our own time. We need only mention the coloured gravel phase of gardening, now happily vanishing. Mr. Goldring's knowledge of our garden flora, obtained at Kew and elsewhere, should save him from the need of ever seeking any embellishments for a garden but those of Nature's ample giving. No doubt even this kind of plant-knowledge may be overdone, and we can imagine no worse prospect for our private gardens than the emergence of a body of landscape-gardeners, trained in botanic gardens with that stiffness supposed to be needed by science. But eight years spent by Mr. Goldring in visiting the gardens and country seats of England for THE GARDEN have shown him how much beauty these possess, where quiet, simple, English ways are followed, and where natural beauty is not shut out by Paxtonian or Nesfieldian excess or formality. It would be well for English gardening if competent young men of this sort, absolutely untrammelled by trade influence of every kind, should devote themselves to the design and planting of our gardens. Mr. Goldring has lately gone to live at Kew, where his address is 52, Gloucester Road.

Annual Chrysanthemums.—These form a very interesting group of summer and autumn flowering plants. They are very showy in the garden and well adapted for cutting purposes, and they are also easily grown, as the seeds can be sown in the open ground, and the plants will do well in any good garden soil. *C. coronarium* is the oldest in point of time, as it was introduced from Sicily as far back as 1629. It is also known as the Garland Chrysanthemum. Originally a single yellow form, of late years English gardeners have grown two selected double forms, one yellow and one white, and more recently the last has developed into a variety with quilled petals. A few years ago I saw advertised an Austrian Daisy, and having obtained some seed, found it to be the single yellow form of *C. coronarium*, in all probability not much changed from what it was when first introduced to this country. Two fine selections with double flowers have been made from this, viz., *Aurora*, yellow, and *The Bride*, white, and when the flowers are produced full and of the best symmetrical form they are charming in the extreme. When a good type of each is obtained it would, perhaps, be best to propagate it by means of cuttings. *C. carinatum* or *tricolor*, the keeled Chrysanthemum, came from Barbary about 1796. This is of diverse colours, but several

fine forms have been selected and named, such as Burridgeanum, crimson, white, and yellow; atrococcineum, deep red-crimson; Eclipse, in the way of Burridgeanum, but with more scarlet in the colour; W. E. Gladstone, crimson; Lord Beaconsfield, crimson, variegated; Sultan, maroon; purpureum, purple; and, latest of all, Golden Feather or Cloth of Gold, a form of Burridgeanum with golden foliage. Then there are two double forms of it known as Dunnett's Double Yellow and Double White. It is right it should be stated that all the before-mentioned forms are more or less sportive and vary considerably at times, but all are very attractive. To this list may be added the common Corn Chrysanthemum, *C. segetum*. This is a charming annual variety also, and, like

ing these flowers. The varieties I have are Cloth of Gold, two varieties of a double magenta Croussi fl.-pl., the old double white and double lilac, the early double sulphur, a double black named King Theodore, a double red, which came to me from Ireland, named Pampadour, a magnificent Primrose, quite the gem of my collection. With the exception of Croussi fl.-pl., all the other varieties mentioned are on the north side of my rockery, and get no sun all the year round, being sheltered from it by the rocks; this suits them exactly. My experience is that the sun is fatal to the growth of double Primroses, as indeed it is to most of the single varieties. Planted on the north side of a rockery, where the sun cannot reach them, in deep loam and peat, I find all Primroses, double or single, to flourish and bloom profusely.—H. A. W.

Young tree of *P. Cembra*. (See p. 104.)

all the foregoing, very free. I think that very fine specimens of the *C. coronarium* group might be grown in pots for conservatory decoration, but they should be plants raised from cuttings to ensure good varieties. The plants should be struck as early in the spring as possible, and then grown on into size, stopping freely at times so as to encourage a bushy and free-branching habit, and when they have made fine specimens and become well established in pots be allowed to flower. The experiment is worth trying, and the result would, I think, amply reward the trouble that would be expended in cultivating them in this wise.—R. D.

Double Primroses.—"R. D." (p. 65) invites readers of *THE GARDEN* to give their experience touch-

The New Zealand Veronicas have been put to the test of our climate during the past few weeks, and in gardens where they have been left unprotected one can see, now the frost is gone, which are the hardy and the tender. The hardiest of all is without question the now well-known *V. Traversi*, which has come through the frost perfectly uninjured, looking now as fresh and green as in summer, so that it may fairly be placed among hardy Evergreens. The broad-leaved species, such as *V. speciosa*, *mixta*, and others, have been punished severely; in some cases they are quite killed, and beautiful though they are, they are unsuitable for planting about London and northwards except against a wall, and even then they need some sort of protection in order to

preserve their foliage uninjured. The pretty little Privet-leaved species, *V. ligustrifolia*, shows signs of injury at Kew, the leaves being browned and otherwise disfigured; but in a garden at Ascot on a light peaty soil I noticed that the frost has done it no harm, but nevertheless it must be classed among the doubtfully hardy kinds. The singular-looking *V. maritima* lately introduced, which looks less like a shrubby Veronica than the others, is quite unharmed at Kew. It is a mere pigmy in growth, but very neat and compact, just the plant, in fact, that a gardener would select for an edging or design. The little *V. pinguifolia*, now common, is unharmed, and its glaucous white foliage has a telling effect in winter on the rockery, for that is its place, as in such a position its trailing growth is best seen. These are a few instances I have noticed as regards the effect of the winter on these New Zealand Veronicas, but now that there are so many in various gardens, others may be found that have passed the winter uninjured. Perhaps Mr. Lindsay will tell us about their behaviour in the Edinburgh Botanic Garden, where I remember I saw a large collection of species—in fact, I believe most of those in southern gardens were distributed from Edinburgh.—W. G.

CANNAS FROM SEED.

CANNAS are so easily raised from seed, that I would rather start with a young seedling plant than an off-set, or a one-year-old plant that had been grown in a small pot. But to be thoroughly successful with seedlings one requires a rather high temperature and to sow early in February; a hotbed answers better than a forcing house, for Cannas not only like the bottom-heat which it affords, but revel in the moist heat, which, in the case of a hotbed, is heavily charged with ammonia—in fact, there is no comparison between plants treated by the two methods. The luxuriance of those grown in a hotbed far exceeds that of those grown in any other way. The seed should be soaked in water for twenty-four hours before it is sown, and the vessel in which it is placed should be set in a warm house if the frame is not ready, so as to keep the water warm. They do not require a hotbed until the seedlings have grown an inch in height, so that if there is a stove or a heated vinery at command the plants may be raised in them. In the meantime, the hotbed must be prepared to receive them, and as the bed will be required to maintain a brisk heat for at least three months, it must be carefully made up. The fermenting material must be well prepared; three parts stable manure and one part Oak leaves are best. The manure must be laid in a heap for a fortnight, and turned over twice in that time to let the strong heat pass out of it. In forming the bed it should be 1 foot larger every way than the frame. It should be 4 feet high at the back and 3 feet in front. After it has been made up about five days, 3 inches of soil should be placed over the surface, to keep down the rank steam, and then the frame will be ready to receive the plants. The seeds should be sown singly in 3 inch pots, and as soon as they have filled these with roots, they must be transferred to 5 inch ones. I should remark that a thoroughly rich soil is necessary; half turfy loam and half well-rotted hotbed manure, to which a sprinkle of sand should be added, is none too strong. I may also mention that the leaves under the hotbed system of culture do not afford a correct idea as to the condition of the roots, for the leaves will rise and unfold themselves much faster than the roots fill up the pot. It appears that the close heated air of a hotbed frame is the best possible imitation of the conditions under which they grow naturally. However that may be, I have been surprised at the size of the leaves and the height of the plants when I have turned them out of the pot, and found, comparatively speaking, so few roots. What roots they do make are fleshy and white, and quickly find their way to the sides and bottom. But it is not desirable to let them

remain in small pots until they get so matted together as to require disentangling. They may in a general way be allowed to grow to a height of 1 foot before they are put into pots 7 inches in diameter. If the plants are required for bedding out they will not want larger pots, and if properly treated they will be 2 feet high by the end of May. Respecting other cultural details, they want a fair supply of root moisture; the water which they have should be warm; this may be obtained by keeping a watering-pot full at all times in the frame. Should the heat in the bed decline too much, which it will probably do by the middle of April, a lining of hot manure should be put all round it, and fresh material should be added to it to keep the height up half way up the frame. To prevent the leaves from scorching, a thin shado must be placed on the glass in very bright weather. If the plants are wanted out of doors, they must be taken to a cold pit at the end of May to be hardened off, and not placed in the open air until the end of the first week in June.

J. C. C.

Culture of Gaillardias.—On turning over the pages of THE GARDEN of July 25, 1885, I note a suggestion which I overlooked at the time to the effect that I should furnish a few hints on the culture of the Gaillardia, a plant which we grow most successfully. If plants established in pots be planted in the open ground in April, 2 feet apart each way, in well cultivated soil enriched with ordinary decayed manure, they will bloom well the same year. A collection consisting of about 1000 plants, which we plant out in the manner just described, has borne the drought of the last five years better than any other herbaceous plant which we grow, and has stood the winters so well without the slightest protection, that we have not lost 3 per cent. of them. Gaillardias are fine plants for exhibition and for cut blooms generally; they are also most useful for bedding; if planted about a foot apart and pegged down they make a brilliant and continuous display, lasting in bloom as they do well into December. The autumn frost does not injure the buds of the Gaillardia nearly so much as those of other herbaceous plants. If grown in pots they make good plants for balconies and verandahs, and also fine specimen plants for exhibition. The following are a few of the best for general purposes, viz.:—

Bethair, crimson, edged with gold, quilled and tasselled	Ormonde, crimson, edged with yellow
Canova, yellow, base of petals light red	Stains, gold, with a slight copper ring around the centre
Fimbriata, yellow, fringed	Temenis, light chocolate, tinged with bronze
Galopin, orange, quilled	Victory, yellow, with a crimson base, and quilled
Josephine, bronze, gold edged	Xenophon, in moon, edged with gold
Larinas, bronze	
Mars, gold, with a scarlet ring	
Roselle, yellow	

—WILLIAM KELWAY, *Lanyport*.

Primula imperialis.—Until a comparatively recent period this remarkable species of Primula was supposed to occur only on the summit of the volcanic peak Manellawangie, in the island of Java, where it was discovered by Dr. Junghuhn, nearly forty years since, at an elevation of 9300 feet, and whence it never descends lower than 9000 feet. It is, however, now believed to be identical with the *P. prolifera* of Wallich, which is found on the Khasyan Hills, in the north of India, and may probably occur in other parts of the Himalayan range, though the Javan plant is said to be superior to the Indian form in point of vigour. The general habit of the plant is that of the well-known *P. japonica*, from which indeed it has been supposed to differ chiefly in its colour, but it is even more robust than that species, reaching, according to Dr. Junghuhn, a height of 2½ feet to 3 feet. The flowers are arranged in from two to four whorls each, bearing from ten to twelve or more flowers, which, to judge from the published figure, are tubularly campanulate in form, and resemble more those of the wild yellow *P. auricula* than those of the Japanese plant, though the yellow colour is deeper than in the *Auricula*. Many attempts have been made to introduce this fine species to European gardens, but, so far as the Javan plant is concerned, hitherto without results, though there appears no sufficient ground for doubting of ultimate success. The chief requisites would

appear to be a moist atmosphere and soil, the plant being found on the margins of the rivulets which meander through the vegetable soil or humus, covering the decomposed lava of the summit. The elevation at which it occurs being 1½ miles above the sea level, it is hardly necessary to remark that the plant flourishes literally above the clouds, and therefore enjoys a serener atmosphere and larger amount of sunshine than the plants growing at a lower altitude. Ice frequently forms at night upon the summit of the mountain alluded to, and the mean daily temperature does not exceed 50° Fah., but the species is unlikely to endure full exposure to our variable winter climate. I am indebted for my small supply of seed of this Primrose to the kindness of Mr. Lynch, of the Botanic Gardens, Cambridge.—W. THOMPSON, *Ipswich*.

Saxifraga granulata.—The single-flowered form of this plant is very common in our meadows, though rarely met with in gardens, and yet the flowers surpass in purity the majority of those of the mossy, or hypnoid, section of Saxifrages. It forms interesting little tufts, sending up in early summer an abundance of large, pure white flowers, which more than repay the trouble of collecting plants of this Saxifrage, which everyone can do, particularly if they reside in the midland counties. The double-flowered form—really a handsome plant—is only to be met with in gardens, and it is undoubtedly the best of the class of Saxifrages to which it belongs. It does well on the rockery, where it blooms beautifully nearly all the summer, and it also makes a charming little plant for the front of the mixed border. It is, perhaps, the easiest of all these Saxifrages to propagate. The roots consist of little grains or tubers, which can be divided to almost any extent. It likes plenty of sunshine and a light sandy soil.—K.

Erinus alpinus.—No difficulty is experienced with this little gem when once it gets hold of an old brick or other wall. It seeds freely enough, and scatters its tiny little seedlings far and near; indeed, in such a place as that just indicated, we commenced its culture a few years ago with a single plant, and now the wall is entirely covered with this pretty alpine. If allowed to have its own way, it gives far better results than when meddled with, and seedlings will be found to have taken hold of every presentable opening all over the wall where a little nourishment can be found. All through the summer months the tufts of leaves are quite hidden, so great is the profusion of its lovely purple flowers. It goes well along with *Linaria alpina*, *Saxifraga stellaris*, and many other of these charming wall-loving alpine, all of which will give good results much in the same way if allowed to grow undisturbed.—K.

Lathyrus Drummondii.—I am glad to be enabled to inform "J. C. B." and all others interested in the growth of this pretty Everlasting Pea that patience in the matter of seed-germination has been well rewarded. As I have already mentioned in THE GARDEN, I sowed the seed soon after it was ripe, I think in last September, in a pan, and placed it in a cool house. It has taken four months to germinate, but at length young plants are coming up well. Possibly a gentle warmth might have been helpful, but, in any case, evidence is afforded that so far from keeping the seed in moist soil all the winter proving injurious, it seems to be the only means whereby at length it can be induced to germinate. I think this remark applies to all hard-coated seeds, and immediate sowing is doubtless better than arbitrary soaking.—A. D.

Tree Flax (Linum arboreum).—The value of this old plant for ornamenting rockwork can hardly be over-estimated; even during very early spring, if the weather has been at all favourable, it is ever ready to push forth its shining golden flowers, a succession of which is kept up until early autumn. In exposed places, however, it sometimes gets partly destroyed in severe weather, but where it can get shelter from cold east and north-east winds, it stands well, and never loses a leaf. In the course of a few years, if planted in a favourable situation, it becomes quite a bush, and the hundreds of flowers which it produces glistening in the sun make a pleasing effect. It was introduced, we are told, by Dr. Sibthorp about 1788

from the Levant, and soon after flowered in the Oxford Botanic Garden. Though quite distinct, it is often confounded with *L. flavum* or *luteum*, as it is often called. The latter, however, is a herbaceous perennial, which, like other herbaceous plants, dies down in winter, reappears in spring, and flowers about midsummer. It is a valuable plant, but not so attractive as *L. arboreum*. It seeds freely, and may be raised in the open ground. In flowers and foliage *L. campanulatum* is not unlike *L. flavum*. It is more slender, however, and is rarely seen in collections.—K.

FLOWERS AND GARDENS.

At the Litton Hall, Leeson Park, Dublin, an interesting lecture on this subject was delivered the other evening by Mr. F. W. Burbidge. The Rev. Dr. Maurice Neligan presided. In the course of his remarks, Mr. Burbidge said one of the best of lessons to instil into the minds of young people is that all flowers are beautiful, for it is flowers that our greatest poets have most delighted to honour. Daisies, Bluebells, Primroses, Daffodils, Snowdrops, and Violets, wild Roses and Woodbine have all been woven into song and story from the time of Chaucer to the days of Tennyson. The one great charm which lingers round our garden blossoms is their beautiful reality. They are essentially genuine. In art and literature generally the poor man must put up with a makeshift, but a Lily, an Iris, or a Pansy in a cottage garden is as real and as beautiful as if grown in the garden of a queen. When we come to consider the early history of flowers, as used for decoration or personal uses, we find that the wild or native flowers were first employed. Of course, all plants are wild somewhere or other in the world, and the most showy of these were at first selected for decorative uses. The Jasmine, Nymphaea, and Orchids of various kinds were so used in India from the earliest times, while in the western tropics the most beautiful of the native wild flowers were also employed long, long before the wood-painted, skin-clad Briton saw ought to admire in a wild Rose bud, or in the flowers of Honeysuckle or of Hawthorn. It is probable that the first plants ever cultivated were grown for use as food or for their medicinal virtues rather than for their beauty; but in the herbarium of the museum at Cairo, and also at Kew and the British Museum, may be seen to-day the mummy wreaths of Egyptian flowers culled by hands and woven by fingers that tingled with the love, warmth, and life-blood of four or five thousand years ago. The oldest of dried flowers in herbaria—that is, of flowers specially prepared for scientific purposes—do not date back farther than the middle of the sixteenth century, and yet we find that flowers were used in Egyptian ceremonies some three or four thousand years ago. About sixty distinct kinds of plants and flowers have been identified, and by placing these in warm water, Dr. Schweinfurth, of Cairo, has succeeded in preparing a series of specimens gathered four thousand years ago. The blue Water Lily, or Lotus, the Poppy, the Larkspur, Flax, Charlock, Knapweed, and other flowers are perfectly preserved, the garlands being woven together with strips of the Nile Reed, or Papyrus of the ancients. I should like to see a garden of not less than a quarter of an acre around every country cottage or dwelling-house, and more especially is it to be desired that a garden should be attached to all country and suburban public schools. In France, Germany, and even in Sweden this is, to some extent, done already with the best results; and I can only hope the day is not far distant when the same may be said of our own public and national schools. Ireland being so peculiarly dependent on land culture for her revenue, I am convinced that elementary horticulture should be more generally made use of as an educational subject of the highest practical or technical value. Nor is this love for cultivated plants and gardens confined to our own country alone, for whoever visits Paris cannot fail to notice the rich profusion of Palms, Dracænas, Ferns, and Daisy bushes or Marguerites with which the windows and apartments there are most tastefully decorated. In Germany, Russia, and also in America the love for beautiful plants and

fragrant window flowers is rapidly increasing. Indeed, the knowledge essential to their successful culture is so easily obtained by observation, that we can only wonder why every window and balcony is not gay with ornamental plants and flowers for a considerable portion of the year. Sweet-smelling things, such as Lavender, Wallflowers, Thyme, Carnations, Rosemary, and Mignonette, should be around every country house; and it is possible that in years to come some part of every town dwelling will be constructed expressly for the culture of plants and flowers within it. A small conservatory, or, at least, window cases, as fixtures, will be considered as essential as a good kitchen-range or a bath-room.

At the present time we have a few roof conservatories and gardens, and, doubtless, in time these and other appliances will become universal, especially in towns, where space is valuable. The best evergreen plant for a room is *Aspidistra luida*, of which there are green and variegated varieties. A specimen here has been grown in a shady window in the Haddington Road for the last four years, and when first brought into the house it had six small leaves only, and it has never been repotted or manured during that time. No other plant I know does better, and it is an especial favourite in France and Holland, where fresh and healthy evergreen room plants are highly appreciated. The India-rubber (*Ficus*) is another good room plant, as is also the graceful *Grevillea robusta*. Several kinds of green-leaved *Drazenas* are thoroughly reliable, as also are small plants of the Australian Blue Gum, or Fever tree. I have seen a fine plant of this in the window of a drawing-room in Clare Street for the past three or four years. Some small Palms grow well in warm rooms, and none better than the *Corypha australis*. Another favourite, especially at this season, is the Arm Lily, while the Scarborough Lily (*Vallota*) is very attractive when it throws up its cluster of scarlet Lily-like flowers in the autumn months, just before the *Chrysanthemum* comes into bloom. Temperance and good gardening generally go hand in hand. Some, at least, among the audience here to-night will have observed those cosy Fuchsia-clad cottages which nestle here and there on the Powerscourt domain, and from which the occupants get ample supplies of good vegetables and small fruits, as well as flowers. Such gardens must prove great counter-attractions to the public-house or shebeen. Another large landed proprietor told me quite recently that his own experience in the building of cottages had proved to him that the addition of a piece of garden ground had a most beneficial influence on the social, moral, and religious life and welfare of the inmates. Of all modern writers, it is Ruskin, I believe, who sums up the whole substance of our knowledge of plants with one dip of his pen. This is his estimate of them—"Timber for the builder's yard, corn for the granary or the baker's oven, flowers for the bride's chamber, and Moss for the grave." In a word, food, shelter, and beauty for all of us is really the sum total of the world's vegetation.

NEW AURICULA SOCIETY.

SCOTTISH florists, with commendable tact, seem to have chosen this year for the inauguration of a Scottish Auricula society. They will, I am sure, have the hearty sympathy of a large body of growers south of the Tweed. If not too late, I would suggest that the name of the society be amplified, and that it be designated "The Scottish Auricula and Primula Society." The national societies in England have for many years offered prizes for Primulas of all kinds, as well as for Auriculas, and it has been decided that both the northern and southern sections should add the name Primula to their schedules, &c. There is a wide field for the hybridist to work in, even if he should restrict his operations to the alpine section of Primulas, to say nothing of the equally large and important range of the Himalayan section. The wonderful development of the Auricula during the present century is a constant reminder to us of the yet undeveloped wonders which we may expect to come from other alpine species under the hands of the hybridist and the skilful culti-

Early in February the numerous varieties of the garden Auricula start into rapid growth, and at that time it used to be an almost universal custom to top dress the plants. This was done by clearing off a considerable portion of the surface soil with a pointed stick, and replacing it with some rich compost. For many years I followed in the same track, and spent several days of the first or second week in February over this operation, but we have now discontinued the practice, as it was found to be quite unnecessary. Mr. Horner in a note written to me two years ago stated that he also had given up surface-dressing his Auriculas for the same reason. This annual dressing was (and by some is still) thought to be an essential part of the culture of the Auricula. Those who sowed seeds of Auriculas when they were ripe in July would obtain a few plants which will now be of good size. They will, therefore, require to be again potted off, but if the seed pots or pans were left undisturbed, a larger number of seedlings will appear now; they will grow quite freely if the weather continues mild, and they should be pricked off as soon as the first real leaf is formed on the plants. Offsets taken off now, planted in small pots, and placed under handlights, will do better than at any other season of the year. Scarcely a single one of them will fail. If seeds have not yet been sown, now would be a good time to do so. The seeds vegetate more freely in a pit from which frost is excluded than they do in an ordinary cold frame at this season. J. DOUGLAS.

GARDEN DESTROYERS.

G. S. SAUNDERS.

Springtail insects.—How can I get rid of some troublesome little insect (one or two of which I send) that infests all my plants, not only in the stove, but also in cooler houses, and even plants that have been out all summer? I take it for thrips, but most books that I have read say that thrips live on the under-sides of the leaves, and can be got rid of by syringing or fumigating; some of my plants get that thrips on the leaf, but they are at once sponged off, and are never allowed to spread, but as these other insects live in the earth and shingle, smoking has no effect on them; they only "wait till the clouds roll by" to renew their depredations. All plants suffer, but *Gloxinias* and *Begonias* are quite ruined by them. I see that steaming has been recommended as a remedy; will you, therefore, kindly tell me to what temperature a house might be raised by steam without doing harm to such plants as *Adiantum farleyense*, &c.; also, if the tobacco-water used is only tobacco boiled in water, or the tobacco juice which is sold, mixed with water? By giving me this information you will confer a great favour, as it is quite disheartening to look at my plants.—W. W.

You have sent us a regular collection of insects—beetles, gnats, flies, and springtails. Only the last-named are, however, hurtful to plants. The springtails are very difficult to destroy, on account of their habit, which you have noticed, of living a great deal among earth, &c.; their great powers of jumping render the task of "putting salt on their tails" all the more difficult. I should recommend taking the plants off the stages and syringing them over a tank with tobacco water and soft soap. The springtails will probably jump off the plants and fall into the tank, where they may be easily, I should think, destroyed; any that remain on the plants will be killed by the insecticide. Before replacing the plants, water the hinge on the stage, and, if necessary, the floor, too, with boiling water from a watering-can with a rose nozzle. As regards steaming greenhouses, there is no need to consider the temperature if it is the steam, or rather vapour, of tobacco-juice which is to be used. M. Godefroy-Lebeuf, who first ventilated this subject in *THE GARDEN*, says he has a number of braziers filled with live coal; on each he puts an old saucenpan containing a pint of tobacco water: "this is quickly vaporised, and

the atmosphere is saturated with this moisture-laden vapour, which becomes condensed on everything with which it comes in contact, leaves, bulbs, flowers, shelves, &c. When the consistency of the contents of the saucenpans is reduced to the thickness of thick soup, a pint of water is added to each, and the vaporisation goes on as before. I consider a pint of tobacco juice sufficient for a house of 2000 cubic feet." The tobacco juice M. G. Lebeuf uses is what he calls 14°. Mr. McIntosh recommends a paraffin stove for supplying the heat to vaporise the tobacco juice, and says, "if the tobacco juice is as good as it should be, it will require an equal part of water added to it to prevent it boiling over." So long as this juice is of the right strength it cannot matter whether it be home made or bought. The tenderest plants do not seem injured by this process.

MARKET GARDEN NOTES.

THE wintry weather that has prevailed for some time has greatly checked work in market gardens. Nothing in the way of sowing or planting can be done until we get more genial weather. Pruning, cleaning, and manuring, however, can be done, and this work too frequently gets put off altogether unless the weather precludes the possibility of getting on with other work. That orchards have been sadly neglected few can deny, but I find that many of them are being renovated, and also new ones planted. Pruning old trees, especially if long neglected, needs great care; if a large quantity of wood is removed at one time the tree gets a serious check, and is frequently more injured than improved. I would never cut any large limbs from fruit trees of any kind, as they leave wounds that induce decay. In pruning standard trees get into the centre with a small hand-saw and strong pruning-knife and cut away all the small spray-like growth that does not get direct sunlight, leaving the main branches quite clear; the outer bearing branches may be left moderately thick. After that is done a dressing with fresh slaked lime if the branches are Moss-covered will soon dry the Moss up, while paraffin will clear the American blight or scale off and leave the branches bright and clear. Carting and wheeling manure on the land has lately been pushed forward, hard frost having made the recently saturated soil in good condition for such work. Under the orchard trees here are growing bush fruits or vegetables, so that owing to the double cropping a good deal of manure is needed to keep the trees healthy. The good prices realised for Apples during the past year have induced growers to pay more attention to manuring their trees than formerly; indeed, there can be no doubt that the great proportion of orchard trees are starved. Night soil and town sewage soon make a marvellous change in orchard trees; the vigour thus infused into them seems to enable them to throw off insect pests, and, indeed, all other ailments. Forcing Rhabarb, Seakale, and Asparagus is now being pushed forward; old tubs are put over the Rhabarb crowns and then they are covered with manure. This is the plan most largely followed here; Seakale and Asparagus are both lifted and forced in frames on hot beds. All spare pits and frames are being cleaned and got ready for work, and seeds of Cucumbers, Tomatoes, and other early crops are being sown in heat so as to have a plentiful supply of plants as soon as the time for planting out has arrived.—J. G., *Hants*.

Names of plants—*D. C. (Stourhead)*.—A form of *Clematis angustifolia*.—*Snow*.—1, *Echeveria retusa*; 2, *Begonia*, apparently *ranunculacea*; 3, flowers shrivelled.—*W. S. WOODS & FORESTS.

A GRAND OLD AMERICAN ELM.

I CAME across a magnificent specimen of this Elm the other day. It is, perhaps, one of the largest and oldest trees of this kind now growing in this country. It is about 100 feet in height, having a spread of 100 feet over a superficial area of nearly 8000 feet. The diameter of the trunk, 3 feet from the ground, is about 8 feet. It is solid for about 15 feet from the ground, where the tree separates into numerous huge branches, several of which are large enough in themselves for the stems of good sized trees of this genus. Each of these secondary stems spreads in turn into hundreds of smaller branches with unusual regularity and uniformity, making the whole one of the most symmetrical and graceful specimens of arborescent growth, for its size, to be found on the Atlantic slope. Drooping from some of the lower branches are many long, pendulous streamers, some of which nearly touch the ground. These, as they sway to and fro in the summer breeze, together with the rustlingsymphony of dense leafage from the immense top towering far above, present a truly pleasing and majestic aspect to any beholder. No one can stand beneath this grand old tree and look aloft amid its maze of branches without reverential respect. As to its age, I am left mainly to conjecture; but that it is already well along in its second century seems certain. And yet, strange to say, there is no sign of decay or decline in vigour to be found in it.

This massive and beautiful Elm, true to its nature, stands in a rich alluvial meadow bottom almost in the shadow of the Catskill Mountains, and not many rods from the versatile margin of a reckless and wayward mountain stream, that begins its career calmly and modestly enough away back amid the rocks and roots of a wild, craggy region, well up towards the sky, where the speckled trout disports itself in its quiet pools, and the shaggy black bear slakes his thirst from its crystal waters. But after leaving the mountain range, and supplying a reservoir for a large city, the stream winds its tortuous way through a fertile region of farms to the Hudson River, and so eventually finds the Atlantic Ocean. In times of freshet it becomes a raging torrent in a few hours, recognising no law, except that of gravitation, which it demonstrates to the consternation of dwellers and property-owners for miles along its borders. A million streamlets tumbling into it from every mountain-side, each with a new incentive, rush for the river, seem to madden it anew, and down go the bridges, the railroads, the houses, the barns, and the crops. It is at these carnival seasons of this innocent creek that this beautiful Elm is saluted by its turbid waters and permitted to bathe its muddy feet therein. This occurs on an average once or twice each year, and I have seen the tree surrounded by a vast expanse of water many times. But just how many hundred such freshets it has witnessed I shall not undertake to say. That it had already attained considerable size in 1777, when the old colonial town of Kingston (now a city of 23,000 inhabitants, in which the tree stands) was burned by the forces under General Vaughan, is an undoubted fact. That it was growing in 1676, when what has since been known as the old senate house of the State of New York, a quaint old stone structure still standing almost beneath the shadow of this majestic Elm, was being erected, is not so certain, though not impossible.

There are several other specimens of this Elm in the same meadow, especially on the edge of

the creek, but none so large and symmetrical as this. A railroad track runs quite near this old historic tree. It is that of the Ulster and Delaware Railway, the main line of approach to the picturesque Catskill Mountains. Every day in summer, hundreds, and sometimes thousands, of visitors and tourists from all lands pass up this road, and this magnificent Elm is admired by all. It is quite possible that it may be remembered by some of THE GARDEN readers.

Kingston, N.Y.

H. HENDRICKS.

SUPPLIES FOR THE WOOD-YARD.

THE stock of unsawn timber in the wood yard should be overhauled at least once during the year, and, with the exception of Oak, as to which there is no special reason why it should be looked to just now, there can hardly be a better time than the present for the purpose. The fellings of most kinds of wood are well advanced, and sales are in full swing. Before, therefore, the cuttings have been disposed of too closely, it will repay those concerned to fix as nearly as may be the requirements for the coming year. There are few places in which Oak is not wanted at some time during the year. This is not always wanted of the largest size, and the thinnings of Oak woods when the trees reach, say, a foot in diameter at half their height are very useful for very many estate purposes. The best and straightest, as a rule, may be allotted for field-gate rails. Experience will teach foresters that with coppice Oak of moderate dimensions this will be one of the most difficult things to get. The shorter pieces, such as hanging and faling styles, will be readily enough found. With posts, again, there is not the trouble, *i.e.*, posts for ordinary gates and fences, as the length to which straight lines are essential is not great. Another purpose for which a supply of clear coppice Oak should be kept in reserve is for cleft pales. To make the best of the wood, trees straight in the butt and with as little sap as possible should be selected for this purpose. The Elm is another tree which is almost indispensable upon an estate, but more for buildings than for field work. The actual working up of the timber may be a little beyond the forester's duties, but still he should have an appreciation of the uses to which it was likely to be put in order to guide him in choosing the supply. A generation or two ago the Elm was very largely used for outside boarding, and for divisions between cattle-yards and the like. There is nothing more suitable for such purposes where hard wear-and-tear are common. The toughness and the difficulty there is in splitting this wood are two of its chief recommendations. There are other hard woods which are used to a considerable extent in the estate yard, but the Oak and the Elm are the chief. With respect to resinous woods, Larches and Scotch and Spruce Fir each come in to a considerable extent, and the present is the season in which the supplies should be replenished. On the Scotch and Spruce a minimum of labour should be expended. I am aware that the Spruce especially is thought but little of in regard to durability, and that it fetches scarcely more than a nominal figure when sold. But if such woods can be used where it is necessary to go to but little, not only in regard to them, there seems to be no sufficient reason why they should not be grown. For fencing and rough buildings which are only required for a few years, such woods may be made to do duty at an infinitesimal cost, as well as anything better, and therefore a proportion of them should always be included in the annual replenishment of the wood-yard.

D. J. Y.

SHORT NOTES—WOODS AND FORESTS.

Pruning trees.—Trees ought to be pruned when set out. How much to cut away from the top depends somewhat on what has been lost in roots during the lifting of the tree. The rule for most trees is to cut away about one-third of the last season's growth, to shorten to a little my very long roots, and cut off enough the ends of such as have been bruised or broken in digging.

The wooden parts of tools, such as the stock of planes and handles of chisels, are often made to have a nice appearance by French polishing; but this adds nothing to

their durability. A much better plan is to let them soak in linseed oil for a week, and rub them with a new cloth for a few minutes every day for a week or two. This produces a beautiful surface, and at the same time exerts a solidifying and preservative action on the wood.

SHELTER-BELTS AND HEDGE SCREENS.

WHAT to plant is a question that some may desire to have answered. The very wealth of material before us greatly enhances the difficulty of making a response. We have deciduous trees that are bare in winter, when shelter is most needed, and we have also Evergreens in great variety, that retain their refreshing verdure all through the year, and provide the most perfect shelter. For the wind-breaks of the field, and even for groves about buildings, the leafless trees have much value, and their judicious disposition will greatly check the cutting storms; the wind, after sifting through the branches, is left of half its power for evil; nor is its force restored for some distance. The majority of wind breaks are composed of deciduous trees, and usually of the commonest species—anything that will rapidly grow into a tree, or that can be most cheaply procured. This practice need not, however, prevent us from using any of the more valuable hardwood, and other trees, in making shelters, but in some instances our impatience may prevail over our judgment as to the more valuable species and induce us to plant only those of rapid growth to ensure a speedy result. As to the use of Evergreens in outside shelter-belts, though more expensive at first, a smaller number and a narrower surface devoted to the wind-break will prove so much more effective than a wider strip of deciduous trees, as to justify the increased outlay. Sometimes even a single row of Norway Spruce, or of hardy Pines, like the Scotch or the Norway Spruce, or even of the common Red Cedar or Arbor-vita will make an admirable wind-break. Plant any of the many trees at your command, and plant them where they will produce the desired protection. Whether you select the so-called cheap trees, such as white Willows, Poplars, soft Maples, &c., or whether you choose Oaks, hard Maples, the white Ash, the Elm, the wild Cherry, the Tulip, the Walnut, and Hickories, or hardy Evergreens, do not neglect the planting of these invaluable aids to good culture. When we come to a selection of the plants best suited to the protection of our houses and their surroundings we again find abundant material from which to make choice. For trees and for tall screens the favourite with many will be the Norway Spruce, which grows rapidly, is easily transplanted and managed, and which presents a welcome tint of green that is always persistent and full. The other Spruces are also desirable, particularly the white and the black. They all bear the knife and shears very well, and may easily be kept within due bounds when used as hedges for shelter. The native Hemlock is particularly commended standing alone, but it is also one of the very best species for forming a screen or shelter hedge, as it may be clipped to a perfect plane, and, when necessary, it can be confined within narrow limits. In the case of trees to be planted about buildings, we should consider their beauty, and with this character in view we should select, among Evergreens, the Hemlock, the White Pine, perhaps also the Red Pine, or Norway, but not the Scotch Fir, nor the Austrian. There we may also place the American Arbor-vita, but the especial function of this species is the formation of shelter-screens and hedges, for which it is particularly well adapted, except in very dry soil; nothing can be prettier than a well trimmed hedge of Arbor-vita, unless it be one of Hemlock, as the latter preserves its deep green hue unimpaired all winter. Some of the dwarf Pines may also find a place in front or at the sides of the house, but they never attain sufficient size to make much shelter. The same is true of the beautiful Retinosporas from Japan, which answer well for low screens, and are highly ornamental. The common Red Cedar is, after all, a most useful plant. It has been called the Poor Man's Evergreen, on account of the facility with which it may be produced in all parts of the country, as well as the certainty and rapidity of its growth. Though not of so fine a colour as some others, this tree makes dense foliage

when set as a shelter-belt and wind-break. It also makes a close hedge to screen pathways.

The ground for the wind-breaks should be well prepared. A strip of one rod in width will be needed if it is proposed to plant but a single row, and several rods wide must be prepared if it be designed to plant a good wind-break of many rows, which is the better plan. After harrowing the ground a furrow is struck for every row of trees, and these furrows may be 4 feet apart, for then the plants may be set every 4 feet. This requires very little labour, unless large trees are selected, and if these be large Evergreens they need not be so close, but more care will be required in planting. Yearlings and two-year-old plants of most deciduous kinds, or stout cuttings of Willows and Poplars, will be the cheapest and best. The young trees, when planted with reasonable care and well fixed in the soil by pressure of the foot, will be sure to grow; but so will weeds, and the plantation must be cultivated for about two seasons, so as to keep down all intruders. With this treatment their growth is greatly enhanced, and they will the sooner shade the ground, when they will suppress the weeds and take care of themselves. They must, however, be protected from the inroads of stock of all kinds. This is an absolute necessity. When to plant, though an important question, need not detain us long. Plant when you get ready, autumn or spring, but be sure to have the soil ready for the reception of your trees before bringing them on to the ground; let it be dry enough to crumble; never plant when it is wet and clammy. Deciduous trees may be set out in autumn, when we have leisure to do the work, and when the soil is dry and warm.—*Rural New Yorker.*

ROOT-CHOKING OF DRAINS.

DEEP as drainage may be laid, it is never altogether free from the possibility of being put out of order by the roots of trees, or of certain kinds of crops which may penetrate the drains, and form a hindrance to the free passage of the water through them. The roots of the Elm, Ash, Willow and other trees are known to enter the pipes, and even pass through the ground for several yards to reach them, as if they were attracted by the moisture and air which they find in the pipes, and by the nourishment afforded them there. To obviate this difficulty it is advisable, where it occurs or is apprehended, to use socket-pipes jointed with cement, or to lay the pipes as far as possible from the trees. I have found that imbedding the pipes in lime, mortar, or concrete has prevented them from being choked, although close to trees which it was impossible to avoid, and has kept them clear for some years. The roots of some crops, if they should penetrate the pipes, die away when the crops are removed, and are frequently washed out at the mouths of the drains by the strong flow of water through them. Other substances give the drafter a vast amount of trouble in obstructing pipes. Ochreous water, depositing oxide of iron, is a common source of obstruction. It appears to harden and consolidate as it receives air through the pipes, and ultimately chokes them. I have found it best to get at the source of the spring or springs, and conduct the water away by large pipes independent of the general system. Confervæ and parasitic plants will also get into the pipes, grow, and ultimately stop the flow of water through them. Another source of trouble is the percolation of sand into the pipes, which necessitates patience and care in taking them up frequently after being first laid and relaid, until all the water has run out of the bed, and then laying them in straw and on strips of wood. P.

Appearance of good timber.—There are certain appearances which are characteristic of strong and durable timber, to what class soever it belongs. In the same species of timber that specimen will in general be the strongest and the most durable which has grown the slowest, as shown by the narrowness of the annual rings. The cellular tissue as seen in the medullary rays (when visible) should be hard and compact. The vascular or fibrous tissue should adhere firmly together, and should show no woolliness at a freshly-cut surface, nor should it clog the teeth of the saw with loose fibres. If the wood is coloured,

darkness of colour is in general a sign of strength and durability. The freshly-cut surface of the wood should be firm and shining, and should have somewhat of a translucent appearance. A dull, chalky appearance is a sign of bad timber. In wood of a given species, the heavier specimens are in general the stronger and the more lasting. Among resinous woods, those which have least resin in their pores, and amongst non-resinous woods, those which have least sap or gum in them, are in general the strongest and most lasting. It is stated by some that in Pine-wood, that which has most sap-wood, is the most durable; but the universality of this law is doubtful. —A. N.

THE GEAN, OR WILD CHERRY.

In a low-lying and rather damp piece of woodland near the junction of the Conway and Carnarvon roads may be seen some of the finest specimens of the Gean, or wild Cherry, to be found in this country. The soil in which these trees are growing may best be described as gravelly loam lying upon slate rock, with an alluvial surface from time to time deposited by the Ogwen River during floods. As will be seen from the following figures, several of these trees have attained large dimensions, and are still in a very healthy, thriving condition. No. 1: height, 70 feet; girth of stem at 3 feet and 5 feet, 6 feet 4 inches and 6 feet 3 inches respectively. No. 2: height, 70 feet; girth of stem at 3 feet, 6 feet 1 inch, and at 5 feet, 5 feet 10 inches. The boles are remarkably clean and straight and with a very gradual taper.

When thinning the patch of woodland in which these trees occur we had occasion to remove several, the timber of which was of excellent quality and remarkable for the large size of its medullary processes, which gave the longitudinal section a bright satiny lustre and rendered it well suited for ornamental cabinet-work.

As an ornamental as well as a valuable timber tree the wild Cherry is but too little known, at least in this country. Many points in favour of it might be adduced, such as immunity from disease, rapidity of growth when planted in suitable soil, closeness with which it can be advantageously planted, and last, but by no means least, value of the timber obtained.

As an ornamental tree the wild Cherry is also valuable, for during early summer, when laden with its pure white flowers, or again in autumn when myriads of the shining black fruit hang in clusters from its branches, it will be readily admitted that few woodland trees have a more lovely or conspicuous appearance. In Scotland, on the banks of the Firth of Forth, and in Devon, many fine examples of the wild Cherry may be seen, ranging in height from 30 feet to 43 feet, and girthing at 3 feet about 7 feet in circumference of stem. This is, however, about the largest size to which they attain in that district, although in many other parts of Scotland much finer specimens may be seen.

Nearly allied to the Gean is the Bird Cherry (*Cerasus Padus*), which also occurs rather plentifully in various parts of Britain, notably the north of Scotland. It is a very ornamental tree, rather more leafy than the Gean, and produces a valuable timber much sought after by cabinet-makers on the Continent. The following measurements of Bird Cherries growing at Darnaway, near Forres, have been kindly furnished to me by Mr. Scott, the wood manager there, and represent the largest trees now growing. No. 1: height fully 40 feet; girth of stem at 1 foot and 4 feet respectively, 5 feet 2 inches and 5 feet. No. 2: from 38 feet to 40 feet in height, and girthing at 1 foot and 4 feet, 4 feet 6 inches and 3 feet 6 inches respectively. No. 3: girth 6 feet 2 inches at 1 foot up (no height given). No. 4: 36 feet in height and 5 feet 8 inches in girth at 4 feet up.

These measurements represent very fine trees indeed, and almost equal to the wild Cherry alongside which they are growing. The Bird Cherry on this estate is, comparatively speaking, a rare tree, in most cases only attaining shrub height. One very fine specimen which I had measured last week is 30 feet in height, girths at 3 feet 4 feet 1 inch, and at 5 feet, 3 feet 9 inches in circumference of stem. This tree

is growing at a considerable elevation above sea level, and in rather damp ground adjoining a mountain rivulet. The exposed situation has told somewhat severely upon it, for many fine limbs have been torn off by the force of the wild mountain blast, which at times sweeps along the valley with terrific fury. It is, however, still an object of veneration, and attracts, by its dilapidated and weather-beaten appearance, the few travellers who pass over the primitive Welsh bridge near which it grows. A. D. W.

SEASONING OF TIMBER.

SEASONING timber consists in expelling, as far as possible, the moisture which is contained in its pores. Natural seasoning is performed simply by exposing the timber freely to the air in a dry place, sheltered, if possible, from sunshine and high winds. The seasoning yard should be well drained, and the timber so supported as to admit of a free circulation of air all round it. Natural seasoning to fit timber for carpenters' work usually occupies about two years; for joiners' work, about four years; but much longer periods are sometimes employed. The best method of artificial seasoning consists in exposing the timber in a chamber to a current of hot air. In one process the current of air is impelled by a fan at the rate of about 100 feet per second; and the fan, air-passages, and chamber are so proportioned that one-third of the volume of air in the chamber is blown through it per minute. The best temperature for the hot air varies with the kind and dimensions of the timber; thus, for Pine woods, in thick pieces, it should be about 120°, and for thin boards of Pine wood, from 180° to 200°; while for Cedar, in boards 1 inch thick, a temperature of from 280° to 300° might be employed. In this way, pieces of timber of 1, 2, 3, 4, 6, and 8 inches in thickness require, respectively, one, two, three, four, seven, and ten weeks to become dry, the current of hot air being kept up for twelve hours per day only. The drying of timber by hot air from a furnace has also been practised successfully in a brick chamber, through which a current is produced by the draught of a chimney. The equable distribution of the hot air amongst the pieces of timber is ensured by introducing the hot air close to the roof of the chamber, and drawing it off through holes in the floor with an underground flue. The hot air on entering, being more rare than that already in the chamber, which is partially cooled, spreads into a thin stratum close under the roof, and gradually descends amongst the pieces of wood to the floor. The air is introduced at the temperature of 240° Fahr. The expenditure of fuel in this method has been found to be at the rate of 1 lb of coke for every 3 lbs. of moisture evaporated. A. NILSON.

How to prevent splitting in the ends of timber.—The cause of timber splitting at the ends is correctly stated in THE GARDEN (p. 88). I have found a piece of brown paper pasted over the ends of a board or plank sufficient to prevent the occurrence of this mischief; but if any signs of splitting have already appeared, it is necessary to cut the paper wide enough to cover not only the end, but also the sides of the plank a few inches on either side a little distance beyond the crack.—B. S.

Tree-growth.—The following figures may interest those of your readers who have paid attention to the growth of trees. I have carefully measured these seven trees annually, and give you the sum of ten years' growth:—

	Jan. 1878.	Jan. 1887.
	Ft. In.	Ft. In.
A Sycamore	7 0½	7 7½
A cut-leaved Alder	8 0	9 0½
An Oak	10 0	10 7½
A Cryptomeria japonica	2 3¾	4 2
A Spanish Chestnut that has been pollarded	13 10	15 5
The above trees are in the garden, the two following in the park:—		
A Spanish Chestnut	12 7	13 7
Another	8 8	9 5

It will be seen that the Spanish Chestnuts grow faster than the other trees, and the pollard the fastest of all. The trees are measured at 4 feet from the ground.—WM. WICKHAM, *Binsted-Wyck, Alton.*

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

FRUIT GARDEN.

W. COLEMAN.

GRAFTING VINES.

ALTHOUGH the Grape Vine was introduced into this country about the beginning of the Christian era, and thousands of pages have been written upon its culture, it is questionable if twenty per cent. of the growers of the present day would undertake the grafting of a set of Hamburgs and guarantee success. And yet, be they owners of only half-a-dozen Vines, how few there are who at some period of their lives have not felt that they would like to try to graft, but have been deterred by the generally-admitted fact that a sure hit is extremely uncertain. Such being the case, and, judging from the number of questions which reach me privately, a few words upon this interesting subject just now may not be out of place. If Vines, like Apples, Pears, and other close-grained fruit trees, could be operated upon with certainty through the months of March and April, there would be no difficulty whatever, as the operator would only have to watch for the rising of the sap when the operation, purely mechanical, could be performed by any handy manipulator. This course, however, would not ensure success, for the Vine being very porous, and having such a powerful flow of sap when growth first sets in, it is more than probable the stock would bleed to death and the scion would be destroyed by flooding. If, on the other hand, the operation is performed when the Vines are at rest, if Vines ever do rest, and the scion, also in a dormant state, is fitted in the most scientific manner, the pores of the wood having become dry and sealed, failure would be equally certain. From these remarks the uninitiated will gather that the great stumbling-block is undue haste, and the chief difficulty rests, not with the operator, but with the director, for it is easy enough to fit cambium to cambium, when, provided stock and scion are in proper condition, the union will take place in a fortnight. If whip-grafting—decidedly the best method—is adopted, the stock may be considerably reduced at any time after the leaves fall in the autumn; but nothing is gained by cutting the Vines down, as it is necessary to get rid of the first flush of sap before the graft is put on, and if a few spurs or shoots can be retained for a time, flooding afterwards may often be prevented.

Assuming, then, that the Vines have started into growth, and the young shoots are several inches in length with fully developed leaves, heading back may be performed, always, be it understood, to a spur in advance of the place fixed upon for uniting the graft. To the tyro whose experience does not extend beyond the Apple orchard, this allowing a Vine to get into full leaf may appear novel, but he must accept the fact—nay, more, he must exercise a great amount of patience—and the better to while away his time he must pay attention to his grafts. The first thing to be considered in the selection of the wood for grafting, as for propagating, is ripeness, and the better to secure this a good stock of prunings from early or mid-season Vines should be inserted in pots of soil, or laid in under a north wall where they can be retarded until quite late in the spring. If the vinery in

which the work is to be performed is a late one, the buds will most likely be on the move by the time they are wanted; if early, it may be necessary to place the scions in heat for a few days, and when the buds begin to swell freely they may be considered in proper condition for working. The stock having made several leaves on each of its young shoots, and the sap in the scion being also on the move, cut the first back to a convenient place for fitting the second, leaving one or more growing shoots above the point of union for the twofold purpose of carrying off superabundant sap and supplying nourishment to the scion until the terminal bud breaks into growth. If the stock is very young, the joining of the inner bark of the one to that of the other will not be difficult, but when the stock is old and rough some care will be necessary, otherwise the two will not meet, but overlap, when perfect union may be doubtful. When the scion is properly fixed it must be tightly bound with bast matting, great care being observed in the protection of the young shoots opposite or beyond, as the loss of these safety-valves will lead to certain failure. This stage reached, a covering of some kind must be applied for excluding wet and air and keeping in moisture. Good grafting clay is often used for this purpose, but the moisture which it contains and receives sometimes induces the formation of roots, and as these are objectionable, if not injurious, nurserymen's grafting wax by many is considered preferable. If the stock shoots are rather long, the points may be pinched as soon as the graft is fitted, otherwise they may be allowed to grow until it begins to push, when they must be checked by gradual shortening. A fortnight will show whether the operation has been successful, and by the end of a month the removal of the wax and slackening of the ligature should be attended with safety. It will not, however, be wise to do away with the ligature altogether, as vigorous stocks force vigorous growths, which after being tied to the trellis, sometimes throw themselves off before the newly formed matter is strong enough to hold them. Although cleft-grafting is not generally approved, I lately saw a house of Vines that were so treated more than forty years ago, and so perfect was the union, that had I not seen the operation performed, I should have doubted the assertion that they had been grafted.

Young gardeners who have not been fortunate enough to see whip or cleft-grafting performed should obtain their employers' permission to try their prentice hands. There are few gardens of any note in which surplus rods are not cut out every year, and these will answer admirably for experimental purposes. If failure follows, they may try again; if success, let them note every detail in their diary, and although the Vines operated upon may be of no value, the experience and confidence gained may be found useful in days yet to come.

BOTTLE-GRAFTING.—This method, although sometimes practised by grafters of Camellias and other hard-wooded greenhouse plants, is, I believe, comparatively new to the Grape grower. It is, nevertheless, an excellent plan, and by many preferred, success being almost a dead certainty. The preparations are in every way similar to those recommended for whip-grafting, only instead of uniting a small scion, a piece of well-ripened wood a foot or more in length is attached to the stock with a long heel for insertion in a bottle of water. When stock and scion are ready take a thick slice 4 inches or 5 inches in length off one side of the graft near the middle, commencing just below the second bud from the top, and leaving 4 inches to 6 inches below for extending into the bottle. Then take a correspond-

ing slice off the stock, notch the two together, as in whip-grafting, bind very tightly with strong string, and apply the grafting-wax. Fill a clear glass bottle with soft water and suspend it with the lower part of the graft inside the neck, which must be kept constantly and regularly filled up to the top. When the Vines intended for bottle-grafting are large and strong, some allow them to burst into full leaf and keep the grafts in the house for a fortnight before they operate. Others, notably Mr. Nash, of Badminton, the most successful bottle-grafter I have met with, put them on at any time after the turn of the winter, and failure is the exception to the rule. Indeed, so successful is Mr. Nash, that I have seen rods of great strength 20 feet to 30 feet in length made in one season, and where two buds were left at the apex of the graft the lower one has made a lateral and borne a bunch of Grapes. By this mode grafts can be attached to any part of a Vine without destroying it, as the bottles, which must be kept full of water—the great secret—can be suspended from any part of the trellis; but the finest rods are secured when one of the main stems is cut down and worked near the ground line.

NEGLECTED GRAPES.

GRAPE MRS. PEARSON.—Although early white Grapes are fairly plentiful, a really good keeper that will hang on the Vines till Christmas and then take its place in the Grape room is worthy of general cultivation. The Muscat of Alexandria to all intents and purposes is a late variety; moreover, it is a host in itself, and many who grow it will say they do not wish anything better, or, if they do, I question if they will ever get it; but no matter how well the Muscat is finished, how rarely do we meet with it fresh and plump after the early part of January. A Grape that is a worthy companion to the Muscat at all times, and can be kept in first-rate condition after that variety is past its best, should be acceptable to growers of late Grapes generally, to exhibitors particularly, and this, I venture to say, will be found in the hitherto neglected Mrs. Pearson. But why is it neglected, when Mr. Barron, in his excellent and exhaustive work on the Vine, gives it a very high character? but, speaking of its merits, says it "requires too much time to ripen." Possibly this short sentence may have deterred some from planting or working it, but then, no matter how precocious a variety may be, it is simply impossible to secure more than one crop in a year, and when Mrs. Pearson, started with Lady Downes, which requires Muscat treatment, is ripe by September, surely this trait is of minor importance, and may be got over by starting early and giving it superior cultivation. The Vine in question was raised by the late Mr. Pearson from the Black Alicante crossed with Ferdinand de Lesseps, and received the Royal Horticultural Society's first-class certificate in 1874. It is a strong and vigorous grower, with thick leathery leaves, which are deeply lobed and toothed. The bunches, above medium size, are tapering, and sometimes carry one shoulder, but generally they resemble an extra fine cluster of White Frontignan, and, having very stout footstalks, contour and build, favour long keeping. The bunches are produced in profusion, and the berries, which set freely without artificial aid, are nearly round from young Vines on own roots, but assume an oval shape when taken from spurs. The skin is rather thick, deep green at first, but takes a rich amber colour when quite ripe, and the flesh, which is firm and juicy, has a strong Muscat flavour.

I have been led to the introduction of these remarks by the examination of some bunches cut from a Lady Downes house at Christmas, and these, as usual, are still fresh in the footstalk, plump in the berry, and look like hanging until April. The Vine from which they were taken is grafted on a Gros Colmar, not perhaps the best

hastening stock for a late white Grape, but the wood is ripe and the Grapes are good—two facts which go far to prove that Vines of opposite character are more accommodating to each other than many people imagine. Mrs. Pearson, having a first-rate constitution, is, however, quite capable of taking care of herself without the aid of the grafter, and requiring, as I am willing to admit, a long season and plenty of heat, would suggest Muscat or Gros Colmar treatment. W. C.

MANURE FOR FRUIT TREES.

ONE of your correspondents inquires if sulphate of ammonia is a good manure for Vines, Peaches, and pot plants generally. Sulphate of ammonia is a very valuable ingredient of a manure for general use, supplying the nitrogen which is indispensable to plant growth; but other ingredients are equally necessary, generally potash, phosphorus, and lime; the most important of these for the Vine is potash; the ashes of the Vine contain 63 per cent. of this salt. Georges Ville, the eminent French agricultural chemist, who has probably devoted more attention than anyone else to the subject of chemical manures, gives the following formula for Vines and fruit trees:—

Calcic superphosphate (dissolved bones)	12 parts
Potassic nitrate (saltpetre)	10 "
Calcic sulphate (gypsum)	8 "

It will be noticed that sulphate of ammonia does not appear in this formula, as the requisite nitrogen is afforded by the nitric acid in the saltpetre, but seven parts of ammonic sulphate and ten parts of potassic chloride, a purified form of kainit, a natural salt which is imported in large quantities from Prussia for use as a chemical manure, may be substituted for the saltpetre, as the two combined produce the same effect; the compound should be used at the rate of about a quarter of a pound to each square yard. This manure is equally valuable for Pear, Plum, and Cherry trees, as the ashes of the fruit of each of them contain more than 50 per cent. of potash, but as the ash of the fruit of the Apple besides 35 per cent. of potash contains 26 per cent. of soda, a proper manure for it should contain soda in some form; nitrate of soda, or even common salt, which is sodic chloride, will answer the purpose. Probably the best formula for plants generally is what Ville calls his normal manure.

Calcic superphosphate	8 parts
Potassic nitrate	4 "
Ammonic sulphate	5 "
Calcic sulphate	7 "

to be used at the same rate of a quarter of a pound to the square yard.—EDWARD TONKS, *Packwood, Knowle.*

—That manure is beneficial to old fruit trees there can be no question, provided they are sound. It should be applied by digging down to the roots, and there depositing a liberal supply of it. But fruit trees too frequently get such food just when they do not require it, viz., when first planted; with youth and vigour on their side they are sure to grow strongly enough in fairly good soil to be fruitful without the aid of such rich manures, as should only be given to worn-out trees. I find it to be far better at first planting to merely mulch the surface with half decayed litter, that will eventually rot away and become food for the surface roots, and to reserve the rich manure for trees that show signs of exhaustion. It is impossible to prepare the soil so as to provide food for trees up to mature age; far better give annual supplies as may be needed. I hardly find two trees alike even under exactly similar conditions; one will be fruitful from the day it is planted, the next will need all sorts of checks to prevent over-luxuriance. But, as a rule, the supply of manure must be very carefully given during the first few years after planting, while older trees can hardly get too much. Starvation is the primary cause of all the ills that befall our old orchards.—J. G., *Hants.*

The Prune Damson.—"B. C. R." (p. 26) speaks highly of what he styles the Prune Damson, &c., the large Worcestershire Damson. I entirely agree with him in his eulogy of this fruit, but I think it is true that it is not a very fine bearer. I plan'd a dozen trees some twenty years ago

During that time twice or thrice the trees have been so laden with fruit that we have been (notably the past year) afraid they would break down. But in many years the crop has been below an average, and sometimes almost nil. The tree when in full bearing, as was the case last year, is a magnificent sight. The beauty and bloom of the fruit are very pleasing. I do not know anyone else in this neighbourhood who grows this Damson, though all admire my fruit, and this part of Berkshire is a great fruit-growing country, but I have been told that in Covent Garden they prefer the small rough common Damson. There is one advantage in the Prune Damson, that it hangs longer on the tree, and does not ripen and go off so soon as the ordinary Damson. This ought to be a strong recommendation for market purposes.—RICHARD HOOPER, *Upton Rectory, Didcot.*

MARKET FRUIT.

IF in a multitude of counsellors there is wisdom, certainly in an army of correspondents there is chaos—at least, such must be the experience of readers of some of our daily papers, which at this dull season have found matter for discussion incidental to the present state of market fruit culture. It is interesting to learn that orchards, even in fruitful Kent, are being grubbed up, because it is unhappily far too notorious that very many orchards are worn out. But when, upon the fact that some orchards are being destroyed, it is sought to erect a foundation for a national lament over the decadence of home fruit culture, the notion seems too absurd to merit a moment's consideration. For how many years past have there not been exhausted orchards in process of annihilation? There is nothing new in that fact, and, indeed, it is rather cheering than otherwise. Then nothing is said with respect to the considerable amount of planting which goes on every year, and which it is certain far exceeds the depletion. Probably it will be found wherever reliable statistics are obtained as to the area of land under fruit culture in this country, that it increases from year to year appreciably. But whilst the recent discussion in favour of home fruit supply has sprung from the assumed grubbing up of a few Kentish orchards, the numerous writers who have sought to enlighten us upon this topic have all been more concerned with the marketing and market prices of the fruit produce of the orchards which exist than with regard to the small acreage which has been cleared of its fruit trees. All the ground now travelled over in the course of the discussion has been gone over scores of times in previous years, but with no better result. We are such slaves to customs in trading, that neither good nor bad fortune seems able to alter our methods of procedure. We go on growing pretty much the same sorts of fruits under the same conditions. We market them in the same fashion. We are pleased if the returns are good, and are sorely disappointed if they are bad; but as to any drastic change with a view to benefit the grower or improve the quality of the fruit or methods of marketing it, or finding other and more lucrative markets, in all these things we do next to nothing, and whenever glutted fruit markets and depressed sales come we are as helpless as ever. The fruit grower has produce perhaps in abundance, but he may be some twenty, thirty, or forty miles off. Clearly his fruit in that case would be valueless on the ground. To be worth anything it must be brought within reach of the consumer; but to do that himself would be to the grower a matter of some difficulty, and certainly expense. He therefore finds it best to take advantage of the middle trader, and through him eventually the fruit is distributed. Now the cost of distribution is, of necessity, considerable, too often adding 100 per cent. to the prime cost of the article. When, therefore, fruit is very plentiful, it is obvious that whilst the cost of distribution cannot be, under existing conditions, reduced one fraction, the brisk competition on the part of growers gives the trader full command of the market, and he can purchase at his own price. Now, if the grower could get his fruit to the consumer direct he might pocket the trader's profits, assuming that he still sold at the same price retail, but if he did the consumer would gain nothing. On the other hand, it is difficult to see

in what way he could make the cost of distribution to the consumer cheaper than the trader, with his special knowledge and facilities, does; hence, under our present system it is difficult to look for better results. We may plead for more markets, and, not least, for comparatively free markets, where consumer and grower may meet without the intervention of the middleman, but that plan if adopted would ruin the trader, and thus create injury in that quarter. But putting even that contingency aside, existing market monopolies are so strong, that the possibility of getting more markets of a retail kind is gloomy enough. Of course, in such case the grower would be saved some of the cost incidental to retail distribution, and the consumer would expect to pay less for the articles for the same reason. After all, it does not seem as if that plan would result in unmitigated good to the grower, but it is certain that more markets for garden produce is one of the needs of the market trade.

One of the great difficulties incidental to market fruit culture is the variability of our climate and the irregular production of crops. Until we really gather our fruit we can never be assured that we have got it; and if two years out of every three yield only half crops, perhaps less, and even then with no form of consecutiveness, how can it be expected that we should be in a position to utilise a big crop to the utmost when it comes? No wonder we have to speak of such a crop as a glut, because our means for its profitable disposal are of so limited a kind. The difficulty seems inevitable in all cases where the supply is so uncertain and so intermittent. That we may improve the quality of much of our fruit is certain, and in doing so render that which is improved also all the more profitable. But then we must not overlook the fact that we shall only obtain enhanced prices for superior fruits whilst that supply is limited and inferior fruit is still grown. Replace all our poor fruit by superior fruit, and quantity alone will bring down the price to the glut-level, and the grower's case will be little better than before. If in the improvement in quality we can also ensure more regularity in the cropping all will be well, because then we shall have no glut. But gluts of anything must be associated with cheapness. In reference to the Plum, that very erratic and perihable fruit, it is urged that the surplus should be converted into jam, or be dried as the French dry their Plums. But as to the conversion of our surplus Plums into Prunes, we could only perform such transition under artificial heat, and here, again, do we feel the difficulties incidental to the irregularities of the crop. Once in about five years only do we get a big Plum crop; the other four we could do with far more of the fruit for ordinary uses than we have to gather; therefore, the proposal to convert our surplus Plums into Prunes hardly excites enthusiasm. Absolutely no course is more prospectively hopeful than is found in teaching the masses how to appreciate fruit, and, whilst in season, to make it a part of their daily food. Even at the moment of our greatest wealth of fruit, the consumption, and, of course, the demand, ought to be quite doubled. A. D.

Pine-growing at The Hendre, Monmouth.

—Pines are well grown here, some fruits shown from this place at South Kensington in December last being over 9 lbs. in weight. Those grown for winter use are chiefly Smooth Cayennes and Charlotte Rothschilds, and those exhibited were typical of the general stock. When I saw them about that time the plants, one and all, were robust and remarkably healthy, their broad leaves being thickly covered with a dense bloom, which is always indicative of a satisfactory condition in the case of Pines. The largest fruits are produced from plants grown in 12-inch pots. These are carefully drained and good fibry loam is used for potting, a particular point being to make it very firm. Loam alone is chiefly depended on, and manures are avoided, with the exception of frequent applications of guano water when the plants are approaching the fruiting stage and afterwards. Leaves are used for plunging purposes, and the bottom-heat is maintained by the aid of hot water pipes. The plants are properly rested previous to starting into fruit, and failures in this respect are few and far between. During the resting period the

temperature does not exceed 60°, and both atmosphere and soil are kept very dry. When started into growth the bottom heat is raised from 65° to 80° or 90°, and the atmospheric heat to 75°, abundance of moisture being maintained. Queens are the favourites in summer, and these are grown equally well as the winter fruits.—CAMBERIAN.

Two good Figs.—M. Glady strongly recommends Figs Adam and San Pietro to growers of this fruit. The first is a very large Fig, and not new. The tree is vigorous and fertile, the fruit coming in bunches of six or eight at the ends of the branches, ripening in the Gironde about July 15. It would, however, probably ripen at Paris about the beginning of August, and form a succession to the "Three Seasons Fig," the earliest of all, the Figue d'Argenteuil, and the Dauphine. In its greyish tint it has some resemblance to the latter, but is larger than that kind. The flesh is white, very firm, tolerably juicy, and excellent. The tree is of branching habit, but one rarely sees the second crop ripen. The July crop being a heavy one, one can dispense with a second crop. Fig San Pietro originated in Dalmatia, and was introduced to Bordeaux by M. Joubert. It differs totally from the first-named. It is, however, very large, but longer, something like a Beurré Clairgeau Pear. In colour it is greenish grey, flushed with violet; flesh red, juicy, very sweet and delicious. It branches freely, fruits of the second crop having been shown before the Pomological Society of France, and highly commended. It was first described under the name of Saint Dominique, another Fig of second-rate quality. It has also been grown under the name of Meclingea.—J. CORNHILL.

SHORT NOTES.—FRUIT.

Red Currants.—The Ruby Castle variety is vastly superior to the ordinary Red Currant; the bunches are larger and so are the individual fruits.—J. C. C.

The Pommeloe.—This delicious acid fruit is, we think, neglected. It is very rarely that an Orange has so delicate a flavour. It ought to be imported much more largely.

Pear Catillac.—We saw at Gummershury House, the other day, some very fine samples of this excellent stewing Pear. It will remain in good condition until March, and in some seasons perhaps until April.

Grapes.—Among Grapes now to be seen about London, the majority consists of Gros Colmar. This is certainly a very handsome and showy Grape, and one that will always command a good price, but as to flavour, it is in most cases only second-rate.

Preserving Filberts.—If covered with dry sand, Filberts will keep for several months without shrinking. By enclosing them in cases perfectly air-tight and placing them in a cool place, they may also be preserved for a year or more. Or they may be kept in jars in a cool cellar with the husks on.—W. A. E.

Easter Beurré Pears.—These have lately been sold in Covent Garden for 2s. a piece wholesale. We commend the fact to Mr. Harrison Weir and others—who advise Grape growing in the open air in England—with the view of showing that it is attention to our best hardy fruits that will prove most profitable.

The influence of the stock on the scion is well demonstrated in the Cherry house at Gummershury Park, where the same varieties of Cherry may be seen grafted on the Cherry and the Mahaleb. Those grafted on the Mahaleb are bristling with fruit buds, while those on the Cherry have not half the quantity.

Fig Negro Larg.—Anyone growing Figs in pots would do well to include this variety. When planted out it seems to grow too strongly and to make too much wood. In pots the reverse of this is the case, the curbing of the roots seeming to aid to its fertility. It is a great favourite for pot culture at Gummershury Park.

Black Hamburg Grapes.—The other day (Feb. 1) we had an opportunity of tasting some Black Hamburg Grapes—part of a second crop of mine ripened in twelve months. The first crop was out during April, 1886; the Vines were then pruned and allowed to grow away in their own way, when they ultimately yielded a fine second crop of good bunches. On comparing their flavour with that of Lady Downes, the Black Hamburg was found to be the best.

Gooseberry caterpillar.—Perhaps some of the readers of THE GARDEN would like to try my plan for keeping down the Gooseberry caterpillar. It is as follows: Dissolve a handful of alum in hot water, pour it into a large can, which should then be filled with cold water, and the trees affected well syringed with it. I have never known this remedy to fail if properly applied.—W. A. E.

Pear Gilles-o-Gilles.—This little-known Pear ought to be in every collection, being in my belief one of the best stewing Pears we have. The fruit is of a large size, the skin covered with dark russetty spots, stalk very long, flesh firm

and sweet, and when cooked the juice is of a rich claret colour. In season from October to February. It is often spelled Gibzil. It is of French origin. Very fine examples of it were exhibited at the Paris congress.

Figs on the south coast.—It may interest some to know that Figs grown in Sussex near the coast pay well in favourable seasons. Anyone visiting Worthing in summer, and interested in Figs, would do well to walk to West Tarring, a mile distant, to see the old Fig gardens there. About an acre is covered with old trees, and on my last visit Violets were growing underneath the trees, which formed a good winter shelter for them. Perhaps there are few places in England where Figs come so early and excellent in flavour as in that neighbourhood. There one could not go into many cottage gardens without finding Fig trees; and some of their owners make from 20s. to 30s. a year by their Figs. The trees receive very little pruning, with the exception of keeping the lower branches off the ground. If young plants are wanted, the best way is to peg the bottom branches in the ground, and keep them there till rooted. Layers of Figs fruit quicker than plants from cuttings or suckers.—S.

SEASONABLE WORK AMONG FRUITS.

STRAWBERRIES.

THE earliest batches by this time will have declared themselves; if blind or flowerless, no time must be lost in getting them removed, to harden off for planting out in the spring; if satisfactory, take advantage of fine bright days, not only for giving a little extra air, but also for closing early, as good speed can be made under such conditions without running the risk of having the leaves and flower-stems drawn. Where forcing is conducted in Peach houses and vineries, the earliest plants, as they come into flower, should be collected together and placed on a light, airy shelf, or in a well-ventilated pit where a circulation of warm air can be continuously maintained. In the Strawberry house proper this precaution is not necessary, as every plant stands with its foliage close to the glass, when the air admitted at the base passes upwards and prevents condensation of moisture on the petals. As soon as the first batch comes into flower and the pollen is ripe, careful fertilisation with a camel's-hair pencil will be necessary, the middle of the day, or whenever the temperature has reached the maximum, being the most suitable time for the performance of this delicate operation. This stage reached, a somewhat higher and drier temperature, always with air, will be advisable, but the organs of fructification being so tender, great judgment must be brought to bear, not only on the admission of cold air without producing a cutting draught, but also on the introduction of a certain amount of atmospheric moisture, without which they may shrivel before they can properly perform their office. Early morning is the best time to syringe the walls and floors, or to turn the fermenting material; and dryness at the root being fatal, liberal supplies of chilled water must be administered when the ventilators are open. Shallow saucers, at one time greatly in favour, are now seldom met with; and it is well, for, much as the Strawberry luxuriates in moisture, it resents stagnant and impure water, which not only elogs and rots the crock roots, but completely deprives them of the invigorating influence of the ammonia-laden atmosphere. A stench-trap filled with water is all very well in an impure drain, but it is not wanted at the base of a flower pot, from which sweet, wholesome fruit is expected for eating; and this being the aim and object held in view, extra attention to watering will work better than flooding in dirty saucers. The Strawberry being a very excitable plant, the temperature, until the fruit is set, should not exceed 45° on cold nights, 50° when very mild, and 5° to 10° higher by day. Times there will be when solar influence alone will run the mercury up to 65° or more, but then, air in proportion being admitted, the plants will revel in this genial temperature, and repay the patience exercised through the inclement weather. Once properly set, and judiciously thinned, the plants may be well syringed, to make them clean, and placed in the hottest house at

command, to swell off their fruit. A moist Pine stove well furnished with shelves near the roof-tree is generally selected, and the greater the heat and the richer the food, the finer will be the fruit. The plants should not, however, remain in this close, moist heat until the fruit is required for table, otherwise it will be vapid and flavourless; therefore, when fully swelled and fairly coloured, they should be removed to a dry, warm, airy house, where, by a gradual reduction in the supply of water, the flavour and aroma will improve, and the fruit will keep for some time in good condition.

Successional plants, in proportion to the stock and the convenience at command, must now be worked forward once a fortnight. If plunged in the open air it is a good plan to convey them first of all to shallow pits or frames, thence, after the pots have been washed and top-dressed, to intermediate quarters to flower and set. In this way a continuous supply of fruit can be kept up until plants in late houses and pits commence swelling off their crops, when retarding instead of forcing may become necessary.

PEACHES.

By this time the trees in many early houses will be in flower, and in a few the fruit will be set. Recently I stated that freedom from aphids during this period is highly important, as it is simply impossible to avoid the loss of the earliest growths, as well as the crop of fruit where fly is in existence, when the flowers begin to expand. Fly in some seasons, both indoors and out, is more troublesome than in others, but this matters not; the only preventive of mischief in the forcing house is moderate fumigation with tobacco smoke, followed by good syringing just before the flower-buds burst. When in flower a brisk buoyant temperature with plenty of air and a moderate supply of atmospheric moisture must be secured; the first by the maintenance of a continuous circulation in the hot-water pipes, the second by damping all available spaces without actually wetting the blossoms, unless the syringe is used for setting the fruit. Taking it for granted that the roots are satisfactory, the temperature and moisture are favourable, once more I must insist on the circulation of air, even if the temperature is lowered a little for a time. Sometimes during very severe weather or keen, windy nights it may be necessary to close the ventilators to obviate the necessity for hard firing, and then even external conditions will favour rapid circulation through the smallest chinks, but when the atmosphere is calm the ventilators should be more or less open, for as well might we hope to enjoy good health in a warm, stuffy room as expect trees and plants to thrive in a non-ventilated forcing house. Successful growers of East Indian Orchids no longer tolerate double roofs, neither do they look upon the hermetically sealed modern sash as an improvement on the open lapped lights now so seldom met with, but seek a compensating balance by punching holes in the brickwork opposite the hot-water pipes, and treat their plants to a warm, but delicious atmosphere in which human beings are not loth to linger. Conditions favourable to tropical plants are favourable to exotic fruits generally, to excitable subjects like the Peach particularly, hence this digression from the cut-and-dry calendar, as I cannot shut my eyes to the fact that many young men engaged in fruit growing close every ventilator on the approach of a shower and treat the life-sustaining atmosphere as a deadly enemy. The art of fertilising the flowers of the Peach being so well understood, a few words on the important operation of

Disbudding may be of service. A healthy tree trained on extension lines produces probably ten young growths where not more than two, or at most three, are required for furnishing the succeeding year's fruit-bearing wood. If we leave too many, not only are the shoots weak, elongated, and sparsely set with imperfect flower-buds, but the foliage is thin and flabby, and the fruit, from want of sun and air, is pale, vapid, and flavourless. When well grown English hothouse Peaches

cannot be beaten, but this end cannot be attained unless we disbud thoroughly; therefore the first operation after the fruit is set is the removal of all superfluous shoots in order to give those left ample room for free growth without becoming "drawn," and whilst providing for an even spread of foliage over every part of the trellis, not excepting the old branches, which sometimes suffer from sunstroke, each leaf should have plenty of room to move when fully developed. Much, as a matter of course, depends upon winter training, as some make their first mistake by laying in too much wood, but assuming that a clear 8 inches is allowed every fruit-bearing shoot, then the base shoot must be laid in, on the upper side, if practicable, to its fullest extent, also one from the point and another from the centre. All intermediate growths, so often left, may then be removed with a sharp knife, or, with fruit nestling at their base, they may be pinched to two or three leaves for a time, and finally removed where Peaches are not left to swell to maturity. In course of time it is possible the centre shoot may be found interfering with the training of the growth from the base—really the fruit-bearer of the coming year—if so, it must be removed piecemeal as tying in is proceeded with. It is truly distressing to see a number of young gardeners laboriously trying to find room for an unreasonable number of pale green watery shoots when judicious disbudding would enable them to do two days' work in one; the foliage would be broad, deep green, and spreading, and every growth left, studded with silvery triple buds, would ripen up the colour of mahogany. I lately saw a fine Peach tree which had not been disbudded at all. It bore a heavy crop of large colourless fruit, some above, some below the trellis, but the gentleman told me they were used in the kitchen, as they did not think them good enough for table.

Thinning the fruit.—This operation, where a good set has been secured, generally goes hand in hand with disbudding, for just as we remove the shoots by a few at a time so do we reduce triples to single fruit and take off the smallest and worst placed first, always bearing in mind that those pointing upwards to the sun are best situated for colouring to the apex. When trees otherwise healthy start weakly, they generally set an abundance of fruit, which really requires bold thinning before a single shoot is removed; the foliage then takes the lead, and the roots, which may have been sluggish, soon respond, but so long as the young growths remain weak or stationary, not one leaf should be taken off, as this process only aggravates the defect we wish to remedy. Trees, on the other hand, which break boldly and set but a moderate crop of fruit, should be taken in hand as soon as the forthright shoots begin to elongate, thinning being deferred until the strongest have been pinched or removed and the crop generally is swelling freely. As Peaches do not feel the strain of the crop until the stoning period arrives, and some of the fruits never reach that stage, an abundance at the outset should be left, particularly on the lower and best ripened parts of the shoots, as it is from these that the final selection for swelling to maturity should be made.

Atmospheric moisture and water.—In my first paper on starting Peaches I stated that a cold, condensing, sloppy state of the house so conducive to the rotting of the buds might be avoided by the liberal use of fermenting materials placed on the floors and borders. This, in the early house, has done its work, but its retention, if not in the way, will do no harm, as moisture and ammonia can be obtained from it when the weather is too dark and cold for direct syringing. Days, on the other hand, having increased considerably and a fair amount of bright weather being now due, it is reasonable to hope that growth may be accelerated and insects kept in check by giving the trees at least one good bath when the temperature is rising or has reached the maximum. The critical time having passed, clear tepid water free from lime, and occasionally a few gallons of soot water, may be used with great advantage, always,

be it understood, in time for the foliage to become fairly dry before nightfall. The roots of the trees, as a matter of course in internal borders, may have copious supplies of tepid water, as it is a difficult matter to over-water well-drained borders when the young growths are making rapid progress. Indeed, it is questionable if dribblers which never reach the drainage are not the cause of much mischief, for, heavily as I water, I have sometimes discovered, when too late, that another foot spread over the swelling season would have been an advantage, but never took blame for giving too much. If old trees which have been over-cropped started weakly and do not show signs of regaining their strength, they may be regularly supplied with diluted liquid or pure water passed through a good mulch of rotten manure; but young ones must not be so treated, as they almost invariably grow too strong, and not unfrequently cast their fruit when the mildest stimulants are applied before they feel the weight of the crop. To such trees a thin covering of clean stable litter will prove beneficial not only in the absorption and evaporation of moisture, but also in drawing the active young roots to the surface of the border.

Succession houses closed early in January must be regularly syringed now twice a day when the weather is fine, and, as a matter of course, fumigated before the flowers open. If the bloom is likely to be heavy, all the pendent buds may be removed by drawing the finger down the undersides of the shoots, and then there will remain a profusion of flowers for fertilisation. Quantity, it must be borne in mind, does not always secure a good set, as enfeebled trees not unfrequently produce thousands of flower-buds, and the retention of all sometimes jeopardises the crop.

The latest houses, now the weather is mild, cannot be too freely ventilated. Already the buds are swelling fast, and as the fruit from these late structures is expected to shake hands with the supply from open walls, now is the best time to retard. Water, as a matter of ordinary detail, must be given in abundance through the hose where this labour-saving arrangement exists, and, if not already done, a good covering of stable litter may be placed on external borders.

NOTES OF THE WEEK.

Epacris—A collection of these at Kew is now very interesting and pretty. The plants are all arranged in one house (No. 4), and among them are the new varieties sent out by Messrs. Veitch in 1886; also various species. The long-flora type is well shown.

Eupatorium Wendlandi.—This useful winter-flowering plant is grown in quantity at Gunnersbury Park by Mr. Roberts, who finds it very useful, both for conservatory decoration and also in the shape of cut flowers. It has long, erect growths, and bears a great profusion of white flowers. It also stands foraging well.

Thyracanthus rutilans.—Among old-fashioned and now almost forgotten plants, this is one of the best. We lately saw it, at Gunnersbury Park, growing in small pots and profusely flowered, its long scarlet racemes hanging down gracefully, being very effective. Anyone with a moderately warm greenhouse might without difficulty grow this plant.

Early Rhododendrons.—I send along with this blooms of *Rhododendron Nobilemum* grown in the open air here in the American garden. It commenced to open its flowers in January 19, and some of our large specimens are covered with flowers.—Wm. KING, *Arddaraoch Gardens, Gleditsdale, Dundee-shire*.

Very handsome blooms and very early; the fact, indeed, of their blooming so early usually leads to their destruction by frost. A race of high-colored *Rhododendrons* has, however, now been obtained not open to this objection.—E.H.

Hamamelis arborea.—We send for your inspection a spray of this Japanese *Hamamelis* cut from a plant growing in the open border at Coombe Wood, and which is, as you will see, very beautiful just now.—JAMES VEITCH AND SONS.

An interesting spray of this early-blooming deciduous shrub, the flowers of which are very singular, owing to their thread-like yellow petals and claret-colored calyx. They are produced in clusters sufficiently numerous to be effective.—E.H.

The Chinese Iris (*I. fimbriata*) is a greenhouse plant comparatively unknown, yet for winter flowering it is invaluable. It is now carrying an abundance of bloom, and will continue to do so until the spring. Each flower is 4 inches across, with petals of a delicate pale mauve, adorned with a large orange blotch in the centre and prettily fringed at the edges. The

flowers are produced on branching spikes a foot or more in height. The plant is an Evergreen, with long leaves gracefully recurved and bright green. It is a plant of the easiest culture in pots; one of those, in fact, that thrives with little or no attention. It may be grown in any ordinary greenhouse, and is a capital plant for placing on any rocky mound in a light position.

Hibbertia dentata is a beautiful greenhouse climber, and, moreover, it is one of the very few climbers in bloom at this season. It is really a twiner, as its long slender shoots twist and turn in all directions, and in this way cover their supports. There is exquisite harmony of colour in the foliage and flowers of this plant. The leaves are of a sort of metallic green on the upper surface, stained with vinous purple beneath, while the great round flowers are of a clear canary yellow. It is a rapid grower, and yet not untidy; in short, it is one of the very best climbers for winter-flowering that could be named. It is one of the many beautiful Australian plants that are disappearing from our gardens, ousted by more modern plants.

Solomon's Seal forced.—The simple beauty of the *Solomon's Seal* is even more enjoyable now than in May, and we are glad to see that forcing it into bloom in winter is becoming a common practice. In several gardens lately we have seen it in greenhouses intermixed with *Valley Lilies* and Dutch bulbs, and we were much struck with its gracefulness as a pot plant. It is not, we believe, easy to obtain good roots of *Solomon's Seal* for forcing, but if a demand for them springs up they will be grown specially for this use, as the *Lilies of the Valley* are. The illustrations we have published lately of the *Solomon's Seal* as a pot plant have induced many to force it into bloom early for vases and the greenhouse.

Pavonia Makoyana.—This stove shrub is usually seen as a small pot plant with a cluster of flowers at the top of the stem. An example of what this shrub is when it attains full size and allowed to develop unrestrained in any way may be seen in the Palm house at Kew. There is there a large spreading bush, 6 feet or more in height, having tall, wide-spreading shoots, each wreathed on its upper part with flowers. These are about 2 inches long, with the calyx of a rich rose-pink, corolla of the deepest plum-purple, and central tufts of stamens of a bright blue. It is, therefore, an extremely handsome shrub, and a valuable one, inasmuch as it always flowers in mid-winter. Those who have small plants of it should encourage a vigorous growth, so as to get large bushes of it, which are very different from puny stage plants. It is now a common and cheap plant in nurseries. At Kew it is grown under the name of *Guethea Makoyana*, but *Pavonia* is its best-known name. A coloured plate of it appeared in THE GARDEN.

Climbing Epiphyllum.—The most beautiful way of growing the *Epiphyllum* we have seen is that illustrated in the great Cactus house at Kew. Under one of the rafters of the roof are trained the long stems of *Pereskia aculeata*, and upon these the *Epiphyllums* have been grafted together with another *Cactus* (*Cereus flagelliformis*). The *Epiphyllums* are now in full flower, and, owing to the profusion of their brilliant carmine blossoms, make a beautiful feature. This mode of growing the *Epiphyllum* may not be new, but it is most unusual, and certainly worth practising in private gardens, for in this way one could adorn the roof of a warm greenhouse or stove at this season when very few creepers flower naturally. The *Epiphyllum* is a beautiful pot plant, but there is a certain formality of habit about it which some object to, but this mop-headed look is quite avoided by grafting it on the long shoots of the *Pereskia*, which is the usual stock for grafting *Epiphyllums* upon. First of all the *Pereskia* must be grown vigorously, so as to get stout stems 8 feet or 10 feet in length, and on these the *Epiphyllums* may be grafted at intervals of a few inches. It is a mistake to graft any other *Cactus* upon the *Pereskia* besides the *Epiphyllum*, or a muddled effect is produced. The specimen at Kew has been grafted about two seasons, and each year it will improve, although now it is a splendid feature.

GARDEN DESIGN.

TERRACE GARDENS.

The accompanying engraving represents the way in which the terrace garden at Lord Eversley's beautiful country seat at Heckfield, in Hampshire, is embellished in summer. The bed shown is one of a series of what may be termed architectural beds, which make up a geometrical design on a broad terrace garden in front of the mansion. In such an important position, therefore, it is necessary that the beds should be made bright and effective; and to do this well is one of the chief cares of the gardener, Mr. Wildsmith, than whom no one knows better the material with which he has to work. He knows that there are many ways of planting lawn beds besides that of massing together so many Pelargoniums, Calceolarias, and other stock-material of the "bedder-out." The terrace bed shown is, we consider, an excellent example of how to fill a large stone-edged bed so as to look informal and graceful, and bright withal.

Bed of fine-leaved plants and flowers at Heckfield Place. Engraved for THE GARDEN from a photograph sent by Mr. Mason Good.

The principal plants used in this composition are Castor-oil plants, which occupy the centre, giving a stateliness to the whole group. Then come Cannas, Abutilons, Marguerites, and over the sides fall in graceful tufts dwarf Nasturtiums, Petunias, and such-like trailers. Such a mixture is not only out of the ordinary run, but extremely effective, and when several smaller groups are seen on a faultlessly-polished lawn, there is nothing to surpass them in the way of terrace-gardening. The same principle of grouping could be carried out even without the raised stone-edged beds, which, being elaborate and costly, are only in keeping with a noble mansion. A simple raised bed may be made with wood, the most suitable being small Larch poles with the bark on, cut about 3 feet long, and driven into the ground so as to leave about 18 inches above it. Some sort of raised bed is necessary to produce the pretty effect which trailers have when falling over the edges in the manner shown. W. G.

Arum Lilies at Kew.—An example of the advantage of planting out Arum Lilies in summer may be seen at Kew. They are planted out in the summer about May in ridges like Celery, and

thoroughly well watered during the summer. In the autumn, before frost touches them, they are lifted and potted and put in a warm place until established. They may now be seen in splendid condition in the temperate house. Solanums are treated in the same way and do well.

FERNS.

W. H. GOWER.

REPOTTING AND DIVIDING FERNS.

REPOTTING and propagation by division of the crowns or rhizomes should be carried out before the plants begin to grow, as Ferns of all kinds dislike having their roots interfered with when making their top growth. Even the removal of the drainage material from the bottom of the ball, if growth has commenced, generally has the effect of causing the young fronds produced immediately afterwards to come deformed. In the case of plants that are divided with a view to their increase, when they are in a growing state, the injury which they receive from the unavoidable breakage of their roots is still more serious. The time

it. The soil ought to be made moderately firm in the pots, and a good watering should be given as soon as the potting is completed. Where practicable, it is well to raise the temperature a few degrees, so as to help the plants to get established, keeping the house closed for two or three weeks afterwards, with more moisture in the atmosphere than has been used during the time the plants have been at rest. In potting *Gleichenias* and other species of like habit that produce long creeping rhizomes, and which are tender and easily injured, if a good deal of care is not exercised, the points of these creeping shoots suffer so that they will not start again. Such of the *Gymnogrammas* and other kinds that require cool stove heat through the winter, and that need a shift, should also receive attention now. The coolest grown portion of the stock that are kept in an ordinary greenhouse temperature may be left a little longer before being potted. With the exception of the kinds that will not succeed without a moderately high temperature, such as the *Gymnogrammas* above named and a few others, it is a mistake to give Ferns so much heat as often practised, as the plants for whatever purpose required are worse for it, and especially so through the excess of humidity sometimes used in the atmosphere, the joint effect of which is the production of fronds that will not retain a healthy appearance on the plants so long as they should, and when wanted for cutting they wither and look unsightly much sooner than when the growth is made in an atmosphere that is neither too hot nor too moist. When Ferns are grown under conditions such as advised, and with the addition of sufficient light by not shading them to the injurious extent that is often done, they are much less affected by thrips, which insects give much trouble by their persistent attacks when the growth is wanting in solidity.

MAIDEN HAIR FERNS.

Now is an excellent time to increase one's stock of the various kinds of *Adiantum*, such as *A. euneatum*, *A. gracillimum*, *A. farleyense*, *A. scutum*—all useful sorts, either in the shape of plants in pots or in a cut state. When Ferns are required for room ornamentation, they should not be grown in too high a temperature, but in plenty of light, so as to render them stocky and able to withstand draughts, to which they are sometimes exposed. From plants hard-cut or that have suffered through adverse treatment, or, as sometimes happens, through brown scale, all the fronds so affected should be removed, cutting close down to the crown, but taking care not to injure the young undeveloped fronds. Some plants should be divided annually, putting them in smaller pots, in which they are most useful for service indoors. Take, for instance, a plant that has the previous year been growing in a 5-inch pot; cut it into four, and each piece will go nicely into a 3-inch pot. Plants in 6-inch and 8-inch pots are generally grown to produce fronds for cutting. Pots for Ferns should always be well drained, as they like abundance of water at the roots during summer, particularly when grown in small pots.

The soil, except that for *A. farleyense*, should consist of two parts fibry loam, one part peat, one part leaf-soil, and a good sprinkling of coarse silver sand and old lime rubbish from ceilings of old houses, to which the roots of Ferns seem partial. Put firmly, and leave an inch at the top in the larger pots for water, and from half to three quarters of an inch in the smaller pots. As soon as potted, set the plants in a vinery, in which there is a temperature of about 55° at night, with a rise of 10° in the daytime. The moist atmosphere maintained for the Vines just suits the Ferns; as more heat is required for the Vines, the Ferns must be moved to other structures, but if a fernery or other house can be set apart for them where the necessary temperature can be maintained with a rise of 5° during the night and more during the day as the season advances, so much the better; but if no other place but vineries or peach houses are at command, they answer well

by moving the plants about as necessity dictates. In summer, however, cooler quarters must be found for them than will be required for the Vines and where shade can be given them, or their fronds quickly become of a pale colour.

Ferns need not be syringed overhead, but a moist atmosphere should be maintained by sprinkling water on the stage and paths in hot weather. Do not water too freely at the roots immediately after potting, but when growth has fairly commenced it should be applied copiously, with occasional doses of liquid manure, say three times a week. The fronds of *A. cuneatum* and of *A. gracillimum* retain their freshness much longer when cut than they otherwise would do if, before using them, they are immersed in cold water for twelve hours, selecting only such as have black seed spores. Fronds in that condition are harder than younger ones, and stand much longer. *A. farleyense* and *A. scutum* are more useful as plants in a growing state than when fronds only are employed, as the latter have a heavy appearance when associated with cut flowers. For plants of *A. farleyense*, the most useful-sized pots are 5 inch, 6 inch, and 8 inch ones. If healthy plants are obtained at first, thrifty specimens can be had in the sized pots named, which will be found useful for decoration in rooms. This variety is better without peat in the compost than with it. Two parts fibry loam with the fine soil taken out of it, one part coarse leaf-soil, half a part lime rubbish, as recommended for the other varieties, some silver sand, and a thin sprinkling of finely ground bones will be found to suit *A. farleyense* well if firmly potted. Copious supplies of water alternated with liquid manure in summer when the plants are growing freely will greatly benefit this variety. E. M.

Selaginella hortensis.—We grow this beautiful Moss in all sorts of temperatures, and it appears just as much at home in a cold unheated fernery as in an intermediate house or stove. Out of doors, too, I saw it the other day still fresh and green after the bitter weather we have lately experienced. I find it to be most serviceable for edging groups of plants in pots: for this purpose it should be in 3 inch or 4 inch pots and in rich light soil. After being potted and set in a shady position in a genial temperature, it soon forms beautiful plants, which then may be removed to a cool house. This Moss is invaluable dibbled in pots containing Tulips and other bulbs. Thus treated it makes a pretty surface covering, and sets off the bulbs to increased advantage. Large specimen plants in pots or tubs are greatly improved in appearance by covering the soil with this pretty Moss, and for dinner-table decoration, if grown in tin or zinc trays, it may be utilised in a variety of ways, and when flowers are scarce it is doubly valuable, either used by itself or as a setting for cut flowers.—J. G.

SHORT NOTES.—FERNS.

Polypodium suspensum. This Fern is admirably suited for hanging baskets, or for draping the face of rock-work in terraces. Its fronds are from 1 foot to 2 feet in length, pendulous, and simply pinnate; the pinnae, which are in numerous in texture, as well as the stems, are clothed beneath with rusty red hairs.

Osmunda javanica.—This an erect growing plant, bearing thick, leathery fronds from 1 foot to 5 feet in height; the fronds are simply pinnate, the barren segments being some 6 inches long and less than an inch wide, shortly stalked, bluntly toothed at the edges, and bright green. The fertile segments are contracted and shorter than the infertile ones; they are made up of numerous oblong clusters, resembling single branches of the fertile portion of the English Royal Fern; they occur mostly in pairs about the middle of the frond. It is a distinct, bold growing, and effective species belonging to the Malay Islands.

Polybotrya Lechleriana. This has a stout, woolly rhizome. It is well adapted for scrambling over rough rocks, climbing upon the stems of Tree Ferns, or in any smaller situation where large and elegant Ferns are required. The fronds are of two kinds—a usual occurrence in this family. The barren or infertile ones, which are very elegant and persistent, are about four times divided, these divisions being much finer and deeper than those in any other member of the genus with which we are acquainted. The texture, too, is firm and hard, and the colour a bright lively green. The

fertile fronds are contracted, and wholly covered with brown soil, which rapidly decay and fall off. It comes from Fern.

STOVE AND GREENHOUSE.

T. BAINES.

CALADIUMS AND THEIR CULTURE.

THESE handsome Aroids have the reputation of being easily grown, and they are, for it takes a considerable amount of indifferent treatment to kill them. But, in common with many things that get the character of being easy to manage, they are often met with in a condition that renders them of comparatively little use outside the stove in which they are grown, from the fact that if they are moved, even in summer, to a place where there is less heat, accompanied with a drier atmosphere than that of the house in which they have been grown, the foliage flags so as to make them anything but ornamental. Leaving out of the question their near allies, the Alocasias, which by common consent are now separated from them, the Caladiums are proverbially thin, soft-leaved plants, especially the newer varieties of Continental origin. Yet despite the natural delicate texture of their leaves, much may be done by judicious cultivation to give them more substance, and thereby enable them to be moved for a time in summer to a conservatory that is kept moderately close, and where when in good condition they are always welcome. The way in which some of the Covent Garden growers who cultivate these plants for market bring them out, especially the beautiful *C. argyrites*, proves what can be accomplished by tight management. Such sorts as *C. Wighti*, that have more green in their leaves than some of the newer kinds, are the best to grow for ordinary purposes. Indigenous to hot countries as the species of Caladiums are from whence the varieties now in existence have sprung, they, of course, require a considerable amount of heat to grow them, but to counteract the effect of this and the naturally soft texture of their foliage, they should be grown in light houses or pits, and stood as near the glass as possible all through the time their growth is being made. It is not enough, as it would seem to be sometimes supposed, to give the plants a fair amount of light after a considerable part of their season's growth has been made, and under conditions that are wanting in this most important point; they must from the first of their beginning to move be kept near the glass, with not too much humidity in the atmosphere. When plants that require stove heat are so placed early in the season, it makes up for the limited amount of air which the time of the year and the state of the weather permit to be given.

The best way of wintering these plants is to allow them to remain through the season of rest in the pots in which they have been grown, in a warm house, with, as a matter of course, the soil quite dry. It is now time to start them, previous to which they should be re-potted in new soil. They are not particular as to the nature of the material in which they are grown—peat or loam—provided it is of a moderately free, open character, and made fairly rich by the addition of rotten manure, such as is procurable from an old hotbed, or that has done duty in the Mushroom house. In common with other quick-growing, free-rooting plants, they require a fair amount of root room, and should have pots proportionate in size to the strength and size the roots have attained. In the case of large tubers that will push up a quantity of young shoots it is well to thin these out moderately when a few inches long, the effect of which will be to throw more substance into the leaves of those that are

retained, at the same time preventing the head of foliage getting overcrowded. The coolest end of a warm stove is the best place for these plants, as it is here that whatever air is given during the early months of the year should be admitted. Thin-leaved subjects like Caladiums cannot bear full exposure to the sun after it gets powerful, as if it does not actually scorch them it destroys much of the fresh-looking appearance that is an essential feature in the foliage. But no more shade should be given than is absolutely required. Caladiums are little troubled with insects, unless red spider happens to attack them, which it often does if the atmosphere of the house is kept too dry. If this little pest is allowed even for ever so short a time to hold possession, it spoils the colour of the leaves so far that nothing can be done to set them right for the season. A regular application of the syringe, which should be used daily, will prevent this insect gaining a footing.

Grown in the way just alluded to, Caladiums are much more useful than when treated in a manner that results in their flagging immediately they are moved from the stove, the oppressive atmosphere of which makes it not the most inviting place in which to see them. When grown so as to give a maximum amount of solidity and endurance to the foliage, few things have a more telling effect than three or four leaves of a medium-sized variety placed loosely along with a few tall spikes of flowers in a large vase; so arranged in water they will last for several days.

Sta'ice Suwarowi.—When well grown this is an interesting plant, and being of easy culture it is just one of those annual flowers that all who have a greenhouse can grow. Some have failed with it through sowing too early; it should not be sown until the beginning of April, and as it dislikes much disturbance at the roots, a few seeds should be sown in a 4-inch pot, and as soon as the plants are large enough to handle, all but one should be pulled out. When this has filled the pot with roots, it should be shifted into another 2 inches larger, in which it may be allowed to flower. The front shelf of a greenhouse suits it admirably; in such a position it gets both light and air, and its long spikes of dark rose coloured flowers are then very interesting. Being hardy, it may also be grown in the open, but I find when so treated, that rain and wind spoil its beauty.—J. C. C.

Italian Bellflowers.—With reference to the note of "D. K." on Italian Bellflowers (p. 8) we wish to direct the attention of your readers to a few more of them, which decidedly deserve to be grown more largely than they are, viz., *Campanula dichotoma*, one of the prettiest of annuals, and of the easiest culture; its flowers appear very early after sowing and are a charming sight, especially when in groups. It grows wild near Sorrento, where it covers the walls with its blue flowers. The white form of *C. dichotoma* which we raised in our grounds is decidedly the most beautiful. It becomes covered with masses of flowers, which have the characteristic peculiarity of standing erect during the daytime, but droop at night. We may add that the flowers are larger than those of the blue kind, and that the plant is not at all delicate as is usually the case with forms of different colours. "D. K." mentions *C. fragilis*, which is abundant between Castellemare and Sorrento up to the mountain Sant Angelo. But there is another very pretty variety limited to the opposite side of the peninsula, and growing exclusively on the mountain Garganus, viz., *C. garganica*, of a decidedly alpine character; this stands somewhat near *C. fragilis*, and has equally dark blue and erect flowers. *C. Tenorei* is also remarkable; it grows on the rocks in the Terra d'Otranto (exactly at the heel of the "boot"). Its stems grow erect, its leaves are oval and heart-

shaped, and the flowers are a fine dark blue. *C. pyramidalis* was once very much grown, but it seems to have nearly disappeared from gardens, and also its white form, which is found on the rocky shores of the Adriatic Sea, but which grows wild also here clinging to walls. This plant with its long spikes attains with us near the sea a height of 6 feet or 7 feet.—DAMMANN & Co., *Hdly.*

EUPATORIUM CANDOLLEANUM.

This *Eupatorium* is one of the most useful of winter-blooming plants. It forms compact little bushes from 1 foot to 2 feet high and as much through, covered with white flowers during January and February. We treat it as follows: Early in March short shoots that have not previously bloomed are selected for cuttings and inserted four or five in a 3 inch pot in sandy soil. When put in we plunge them in a gentle bottom-heat in a hot-bed or under a handglass in the propagating house. As soon as they have emitted roots, we pinch off the points to increase the number of shoots; then pot all off singly in small pots and keep them close until growth again takes place; they are then removed to cooler quarters. An ordinary greenhouse temperature suits them well, and they should be placed on a shelf close to the glass, where they have abundance of light and air to induce stocky growth. Shift into larger pots as may be required: 6-inch and 7-inch ones are good sizes in which to bloom them.

Loam and leaf-mould, rather more of the former than of the latter, and a dash of sand answer well for the first two shifts, but for the final potting the compost should consist of two parts of loam, one each of leaves and material from a spent Mushroom bed, and a sprinkling of finely ground bones. Pot firmly to induce stocky growth. The shoots should be pinched altogether about three times, say up to the beginning of August, after which time they must be allowed to grow as they like. Gradually harden the plants off until they can be removed from the cold frames to an open, sunny position out of doors, where they should be plunged in ashes, thus keeping the roots cool during the summer. While out of doors they must be watered regularly, and occasionally with liquid manure; neglect in this respect soon renders the foliage sickly and disfigures the plants. Towards the end of September or early in October remove them into a cool house, giving them an abundance of air, and if in December they can have a temperature of, say, from 45° to 50° at night and a corresponding rise during the day, flowers will be more quickly developed. Manure water freely given when the flower-spikes show themselves is very beneficial to them. A few light stakes to the strongest shoots are all the support necessary in order to keep the branches and flowers in position.—E. M.

* * * This beautiful Brazilian plant is just now in flower in various suburban gardens, and is especially valuable when white flowers are in great demand. It is a dwarf, compact, much-branched plant, with opposite pale green leaves, and large corymbose heads of *Ageratum*-like flowers, which last a long time upon the plant, and also in a cut state. It is a useful greenhouse plant, and even sufficiently hardy for room decoration. It is more elegant in every way than any other member of the family that has as yet come under our notice.—E. D.

Violets.—I quite agree with all that Mr. Allan says in THE GARDEN (p. 89) in favour of the three varieties of Violet which he names, viz., Marie Louise, Neapolitan, and Comte Brazza. Plants of these here, as with him, are masses of bloom and buds in all stages of development, notwithstanding the fact that we have been gathering from the first-mentioned variety large quantities of blooms since the middle of September last, and shall probably be doing so until the middle of April. Considering the small amount of attention that these Violets require, and that of the simplest kind, it is surprising that one should so frequently be

asked such a question as the following, viz.: "How is it that my Violets only give me an occasional bloom or two; they were put into a frame in October?" In replying to this question, I usually ask another, viz.: "Were your plants bristling with buds when they were put into your frame?" If not, the frame will have no effect as regards making them produce blooms. The protection of the frame assists the development of the buds with which the plants should be furnished previous to their being transferred to their winter quarters. It is essential that young plants should be grown every year, and therefore runners must be taken about the middle of April, when there is usually plenty to be had with a root or two attached to them. Care should, however, be taken to have runners and not divisions of the old plant. The runners should be pricked out about a foot apart in a partially shaded border which has been well worked, and dressed with manure from an old hotbed, in which a considerable quantity of leaves has been used. They will be found to quickly establish themselves, and will in a short time grow into fine plants. All that is required through the summer is to keep them clean by giving them a frequent hoeing, and to go through them two or three times and cut off new runners, which they will throw out rather freely. If these attentions are annually given them, the result will be, as Mr. Allan observes, a prodigious harvest of blooms for eight months of the year. I treat that fine Violet *The Czar* in the same way, as I find young plants not only bloom more abundantly than old ones, but also produce much finer blooms. This variety flowers more or less in the open through the autumn and winter, according to the state of the weather, and in great abundance in spring.—D. UPHILL, *Moriton, Dorchester.*

BEGONIAS IN BLOOM.

At no period of the year are *Begonias* without flowers. In summer the tuberos rooted varieties produce a grand display, and in winter other sorts are scarcely less showy. Amongst the varieties which we have now in bloom are the following, viz., *B. ascotensis*, a free-growing kind, with drooping flowers of a very pretty shade of pink; the sprays of this are very useful in a cut state. *B. insignis*, another pleasing pink-flowered variety, has flowers of a lighter hue than those of the last. *B. Lynchiana*, which has clusters of coral-red blossoms, is among the most showy of all the winter bloomers, the only objection that can be taken to it is its inclination to run up rather naked at the bottom; even if stopped when young it seldom breaks out in a satisfactory manner. I have had seedlings form more bushy specimens, but my experience of raising this species from seed is, that even if taken from the best and deepest coloured form, few, if any, are in this respect equal to the parent. Between this kind and the perpetual blooming *B. semperflorens* some hybrids have been raised, but though sent out under different names there is so little difference amongst them, that not more than one kind is required. Those known as *semperflorens gigantea rosea* and *carminata* are very like *Lynchiana*, but rather more inclined to assume a bushy habit than that sort does. Another under the name of *semperflorens elegans* partakes rather more of the characters of *semperflorens*, the parent plant. The good old *B. fuchsoides* with its bright coloured blooms is one that must not be omitted, and another of this class which is, like the last, thoroughly at home when treated as a pillar plant is *Ingrami*. Of white-flowered kinds, one of the handsomest is *Carrierei*, especially when grown in the shape of little bushes.

A variety sent last year from the Continent under the name of *Carrierei villosa* in many respects resembles the last, but the whole plant is covered with hairs, and it is besides remarkably free as regards growth, forming as it does quite a little bush. The old *B. nitida*, with its clusters of white flowers, is a well-known, but very useful kind; while in *B. socotrana* we have a species totally distinct from any of the others, and one that

should find a place in every garden. A near relative of the well-known *B. weltoniensis* is *hybrida eoccinea*, whose pretty little red blooms belong more particularly to the early winter than to the present season, though there are still a good number of flowers remaining on plants of it. A useful variety that is just now unfolding its first crop of blooms is *Gloire de Sceaux*, a kind which, under favourable conditions, will flower till spring is well advanced. It is said to be the result of a cross between *B. socotrana* and *B. subpeltata*. The habit is stout and vigorous, and it naturally forms a compact, pyramidal-shaped specimen, densely clothed with foliage. The leaves are of a dark, metallic green tint. The flowers are large, borne freely in good-sized clusters, and of a very pleasing shade of pink. The *Begonias* just named constitute a good and representative selection of winter flowerers. One circumstance that tends to make *Begonias* popular, apart from the beauty of their blossoms and the season at which they are produced, is the fact that they are of easy culture, and in a general way suffer but little from insect pests. H. P.

Diosmas.—These old-fashioned hard-wooded greenhouse plants have unfortunately been elbowed out of many gardens by new introductions, which in some respects are not so good as the plants which they have replaced. *Diosmas* were to be found in most gardens a quarter of a century ago, and generally in the shape of plants of rather large size, from which greenery could be cut in quantity, and it was always acceptable, for not only is the foliage of many *Diosmas* delightfully fragrant, but the branches are so graceful, and last in such good condition so long when cut, that I know of no plants of like character that can take their place. Their slender shoots associate well with the choicest of flowers. As flowering plants I cannot say much in favour of *Diosmas*, but as the blossoms are pure white and thickly set upon the branches, they are not altogether unattractive. Half-ripened shoots strike readily in gentle bottom-heat, and as regards soil, loam, leaf-soil, and a sprinkle of sand are all they require. I may add that if the roots are well cared for, the plants may be cut from as much as desired, but it is during winter, when the growth is hard and the leaves fully grown, that they are the sweetest and last the longest in a cut state.—J. C. C.

Hybridising Primulas.—In the case of this class of plants the skill of the hybridist, rightly directed, may in a few years effect wonders. Even wild forms raised from seeds and grown in gardens produce many variations. The tendency of purplish coloured species when crossed with each other is to produce yellow varieties, and I have a notion that if a yellow or primrose coloured Chinese *Primula* is to be produced, it may be through the bluish coloured varieties, with or without the agency of a yellow-coloured distinct species. Crossing of *Primulas* is a much more delicate operation than crossing *Orchids*, because of the smallness of the parts employed, and the liability of the flowers to become self-fertilised before foreign pollen can be applied. I have crossed many varieties of *Primulas* and *Auriculas*, and it is interesting to trace the resemblance of both parents in the seedlings. In order to be sure of the flowers not being self-fertilised it is necessary to remove the stamens before the pollen bursts from the cases, and this should be done before the flowers open. A pair of very sharp-pointed scissors is necessary to open the flower-bud, and, if the plant is in a pot, hold it in an inverted position, and the stamens will fall out when cut off. If the plant is in its natural position they fall down the tube, and may thus reach the stigma. Sometimes the stigma protrudes from the mouth of the tube, and in that case is easily reached, but in other flowers it does not rise higher than half up the tube. Both parents should be in the same state of forwardness when cross-fertilisation is being attempted, and the right time is about two days after the flowers have been fully open. I have never covered the plants in any way to keep insects from them. If the pollen has been effective the petals will speedily fade. If the flowers are fertilised in March

or April the seeds will be ripe in June or July, and may be sown at once. That is Nature's method of dealing with them. Not all the seeds, nor even the largest portion of them, will vegetate, but some of them will do so in the course of a few weeks; the remainder will rest in the ground until the following spring, when they will vegetate freely. Those who hybridise say that seedlings have a tendency to produce flowers having the appearance of the pollen parent, while the plants, in their general character, resemble more nearly the seed-bearing parent. This is, however, not always the case.—J. DOUGLAS.

Neja gracilis.—It is to be regretted that this graceful little plant is not hardy in the open air; we have left it out several seasons, and have even given it the protection of a handlight, but it has always succumbed to the cold. It makes up for all this, however, by flowering freely at this season when treated as a cool greenhouse plant; indeed, it flowers more or less all through the winter months if kept from the cold; and as it is easily increased by cuttings, there is no fear of its being lost. The generic name *Neja*, about the derivation of which there has always been so much mystery, has been superseded now by *Hysterionica*, a name that will be harder to go down with gardeners than the other. *H. falcata* is another species nearly allied to the above, more robust, however, and without the hairs so prominent on *gracilis*; the flowers are larger, are orange-yellow, as in the other, but not so freely produced. It may be propagated freely by cuttings.—K.

Diseased Tree Carnations.—I send for your inspection some shoots of Tree Carnations which appear to be diseased. At first the foliage becomes spotted, and afterwards the stem, and in a short time the plant dies. Some two years ago a few named sorts were purchased from a nursery, and on their arrival some had an appearance similar to what I describe. Since that time some of my other plants which had previously done well gradually dwindled and died. The plants have received every attention, and, except during the very hottest weather, have been growing in a light, cool greenhouse. Any suggestion as to eradicating the evil would be thankfully received.—J. C., *Seecooaks*.

* * * The decay of the leaves in your case is not exactly a disease, but is caused by bad management. Try to obtain good cuttings now, and strike them in a forcing house. When rooted pot off the plants singly in small pots, and keep them growing on gently in a warm greenhouse on a shelf near the glass. About April they will be strong enough to be placed in a cold frame, and as the roots fill the pots they may be shifted into larger ones. Whenever the weather is fine admit air freely. When all danger of frost is over the plants may be placed in an open position out of doors, where they will succeed well—better, indeed, until the end of September than in any position under glass. By that time they may be placed in 5-inch, 6-inch, or 7-inch pots, according to their size and vigour. They should also be placed in an airy greenhouse, and they will flower well in October, November, and December, but the temperature should be kept up to 50° or 55° as a minimum. The old plants had better be thrown away when sufficient young stock has been obtained.—J. DOUGLAS.

SHORT NOTES.—STOVE AND GREENHOUSE.

Tree Carnations.—We saw the other day at Gnummersbury Park a fine Tree Carnation named Mrs. Keen. It is the darkest Tree Carnation we have seen and very dwarf.

Chinese Primulas.—Among the many forms of Chinese Primula now common in gardens, we lately saw one which is both distinct and pretty, viz., Cottage Maid. Its flowers are large, of good form, and irregularly blotched with red.

Cyclamens.—Of these there is a fine collection at Gnummersbury Park, where they make just now an imposing display in one of the houses. Their colours vary from pure white to intense purple. The individual flowers, too, are very large and of great substance.

Habrothamnus elegans.—This, flowering as it does at this season, is very useful, as it yields its bright pink blossoms in such quantities as to be thoroughly effective. The treatment which seems to suit it best is to cut it close back about July, and let it rest for a little time; then water it, and the result will be a rich harvest of bloom during winter and early spring.

Urceolus pendula.—This plant, better known as *U. aurea*, has lately been flowering freely at Gnummersbury House. Its usual time of flowering is in summer, but by starting it into growth at different periods it may be brought into flower at any time. During the growing season it must be kept in a moderate heat and have plenty of water given it. When at rest the temperature must be lowered and water withheld.

SEASONABLE WORK IN PLANT HOUSES.

CAMELIAS FOR EARLY BLOOMING.—With a sufficient stock of these plants, and the requisite attention to see that they are started into growth at different times, there is little difficulty in having a succession of flowers from autumn until spring is far advanced. Where some of the plants are wanted to come in another year earlier than they have previously been, all that is necessary is to keep them in a growing temperature for a longer period than they have been hitherto subjected to, so as to get their flower-buds further advanced. With this object in view, any plants that have now done flowering should be at once placed in a house where a genial growing temperature is kept up; something like 55° in the night will answer for them. Camellias when strong and healthy have an abundance of roots, which are in an active state during the time top-growth is going on; these require the soil to be plentifully supplied with water; the plants should also be frequently syringed overhead. Where, on the other hand, the plants are deficient in vigour, the roots are correspondingly weak, in which case water must be given more sparingly, or it will be likely to do harm.

GLOXINIAS.—The tubers of those plants that were dried off last autumn should now be started, shaking away all the old material, and re-potting in new soil that is moderately light in texture, and not poor. Give pots proportionate in size to that of the tubers. Large old roots make a fine display, but must not be pinched for pot-room, or the duration of their flowering will be short. Moderate stove heat wherein to start and grow the plants will suffice, keeping them well up to the glass as soon as the tops begin to move. Some *Gloxinia* seed should now be sown; when put in thus early the young plants will flower nicely towards autumn, at which time they will come in useful to succeed the older stock. So much improvement has been effected in *Gloxinias* in recent times, that seed of a good strain may be depended on to produce flowers much in advance of the best-named varieties that used to be considered alone worth growing.

ACHIMENES.—When well managed, few plants are so effective as *Achimenes*, especially when grown in hanging baskets, to which method of cultivation they are better adapted than most free-blooming subjects. For warm conservatory decoration when grown in this manner and associated with baskets of Ferns they have a charming effect. To do justice to the plants, the baskets should be large enough to hold a sufficient quantity of soil to support the growth in a way that will preserve the foliage in a healthy condition. The brown, rusty-looking leaves of these plants when the root room and sustenance are deficient, so far detract from the appearance of the flowers as to make them of little worth. To give a succession of bloom, some of the stock should now be started in pots as well as baskets, being careful to avoid crowding too many of the tubers together. Soil such as advised for *Gloxinias* will answer for them.

GREENHOUSE.—Heaths and other hard-wooded plants that are at all liable to the attacks of mildew should now be carefully looked over; the use of fire-heat and the confined atmosphere of the houses rendered necessary by the severe weather we have experienced will have set this parasite into activity wherever a trace of it has existed. Syringing overhead with water impregnated with sulphur, or some of the various preparations of sulphur now available, or the old remedy of dusting the affected plants with flowers of sulphur will destroy mildew. Where sulphur is applied, it is necessary to take means to prevent any remaining on the surface of the soil, or it will get washed down to the roots, where its effects would

be most injurious, if it did not kill the plants outright. If the plants are syringed with sulphur-water, it is equally necessary to keep it from reaching the soil, or like results will follow. As the different varieties of late autumn and winter Heaths complete their flowering, they should be cut back, removing about three-fourths of the length of growth the principal shoots made last summer. If less than this of the previous season's growth is left, the chances are that the plants will die, as even the freest-growing kinds of Heaths are impatient of their growth being too much reduced. After cutting in, keep the plants a little warm, which will encourage them to break, at the same time being sparing of water until some young growth is made.

ORCHIDS.

W. H. GOWER.

BOLLEAS.

THIS genus is now botanically united to that of *Zygopetalum*, but, however correct this union may be from a scientific point of view, there still remains certain differences both in foliage and in flower which enable the cultivator to distinguish them. Their flowers possess remarkable shades both of blue and purple; their structure, too, is peculiar, and so also are the requirements of the plants; in fact, the wants of *Bolleas* and *Pescatoreas*, and those of their near allies, the *Batemannias*, *Warszewiczellas*, and *Huntleyas*, do not seem to be thoroughly understood. Too much is generally expected from them. Growers of them are not satisfied if they do not retain their leaves for an indefinite period, and also produce an abundant supply of bloom, conditions under which they do not appear to exist in a wild state, large leafy masses of them being seldom found in New Grenada. "*Bolleas*," says a resident there, "have a long season of rest, during which they become very much shrivelled and lose quantities of their leaves entirely, but at the proper season they produce an immense number of beautiful blooms. I think the reason why Orchid growers in England fail to bloom these plants properly is because they do not give them sufficient rest." So much for *Bolleas* at home, but their value here is estimated by the amount of healthy, vigorous leaves which they possess. If many turn yellow and fall off during the resting period, however such a condition may conduce to the general health and floriferousness of the plant, its appearance is thereby by no means improved. What we want to learn, therefore, is how to treat *Bolleas* and allied genera so that we may enjoy the rich green of their foliage, and at the same time have abundance of flowers. A grower who has been tolerably successful with these plants says: "I have always found *Bolleas* and *Pescatoreas* rather difficult to manage, and although we are told that they are mountain Orchids, they will not succeed side by side with *Odontoglossum crispum*. They appear to enjoy plenty of shade and moisture, and a situation where the temperature does not fall lower than 60°. Peat, Sphagnum, and charcoal are our potting materials. If their roots are disturbed they are apt to die off, and the leaves suffer in consequence." Another who has been tolerably successful with these plants says: "Our *Bolleas* thrive best in baskets and on blocks; those tried in pots have not been by any means satisfactory for any length of time; they succeed well upon old stems of Tree Ferns, and do not appear to like having their roots covered. Of course, the extra labour needed in dipping and syringing them during the growing period is considerable, and the care required during the resting season to keep them just sufficiently moist to prevent the leaves falling off is very great."

The experience of others goes to prove that they like a fair share of heat and moisture. *Bolles* and *Pescatoreas* both dislike being exposed for any length of time to a lower and dryer atmosphere than that in which they have been grown. Although there may be no shrivelling, they speedily lose their leaves. Our own experience convinces us that these plants enjoy an abundance of light, but yet not very strong sunlight. They like a quiet, humid atmosphere, and if upon blocks, an almost continual dripping or running of water over their roots; the temperature of the warm end of the *Cattleya* house suits them in summer, and it should not fall lower than 60° at any time during winter. The shrivelling system we have not tried. Concerning *B. celestis*, a glance at the annexed illustration will give a better idea of the general appearance of these plants than a volume of words. The photograph from which the woodcut was prepared was sent to us by Mr. G. Fowler, Quarry Bank, Malton, and certainly represents a finely grown and well-flowered specimen. The leaves, which are from

sepals and petals are rosy pink of various shades; and the lip, which is small, is yellow and ribbed in front. *B. Lawrenceana* is a smaller plant than the last. Its flowers are about 4 inches across; the ground colour is white, suffused with violet or violet-mauve, and the lip is rich purple in front, bright yellow towards the base, and bordered with white. The column is large, and white in colour.

ORCHID CULTURE.

J. DUNESAY Mr. De Crawshay and "J. D." are as good general authorities on Orchid culture as could be found, but Mr. De Crawshay evades the question at issue. It was not concerning "Orchids bought, grown, and sold judiciously" that I wrote; indeed, I specially excepted these, and referred to Orchids as generally bought, grown, and disposed of in private places, and as he does not take up this point at all, I need say no more in reply to him, except that my authorities for stating that Orchid culture is on the wane are those who have never done anything else but bought, grown, and sold

now worth? what the cost of culture is? and what is the value of the returns? This information about a collection that paid would settle the question in regard to those that did not, and we wait a reply on the subject. What I desired to point out was that where results are looked to in the shape of flowers in sufficient abundance and the expenditure allowed is limited, it is well worth any proprietor considering whether he had best spend his means on the numerous fine hardy and greenhouse plants of easy culture and cheap, or upon a few that will cost much more, and the culture and returns of which are so very doubtful.—W.

— There can be no doubt that Orchid blossoms possess the richest colours, the most singular shapes, and the most delicate fragrance of any flowers produced by plants that we cultivate. They are also equally floriferous, if not more so, and their flowers last as long in beauty as those of any plants with which I am acquainted. At the same time, I may say that Orchids cannot be grown by such numbers of people as can grow many other plants—Roses, for example. If, however, we take a garden in which a general collection of stove and greenhouse plants is cultivated, no one can gainsay the fact that a well-grown *Vanda*, even when destitute of flowers, is not as effective and graceful in appearance as the majority of other plants, whilst *Cattleyas*, *Cypripediums*, *Oncidium*s, and *Odontoglossum*s are quite as presentable when out of flower as *Heaths*, *Ixoras*, *Dipladenias*, and such plants under similar conditions, always assuming that their particular requirements are studied, careful attention being just as necessary in the case of Orchids as in that of other plants, but not more so. Difficulty of culture, therefore, should not be pleaded as an excuse for banishing Orchids from our gardens. That the demand for Orchids is diminishing is not confirmed by every-day experience. The fact is, Orchids have to be imported at a great outlay and good kinds are dear; therefore a sufficient number of new growers may not start up to keep trade in them as brisk as in the case of plants which are raised at home by thousands from seeds or cuttings. Lovers of Orchids are, nevertheless, continually on the outlook for novelties just as eagerly as those whose tastes lead them to cultivate *Auriculas*, *Carnations*, *Dahlias*, *Chrysanthemums*, *Primulas*, *Cyclamens*, or any of the numerous forms of plants which embellish our greenhouses and conservatories. The difficulty and expense attending the importation of new Orchids naturally, as I have said, make them high-priced, and thus the demand for them is somewhat restricted; but anyone beginning to form a collection can purchase good, showy, free-growing Orchids almost as cheaply as they could a corresponding number of good greenhouse flowering plants, and they will be able to cultivate them with even greater ease than they would a *Heath*, for example. As to profit, private growers do not look for that in Orchids any more than they would in *Heaths* or similar plants; ornamental gardening does not admit of being looked at from that point of view. It is a luxury, and therefore is never expected to yield a profit.—H. G. W.

— All growers of Orchids will be glad to see that the sweeping condemnation of Orchids and their culture which "W." so undeservedly gave these beautiful flowers was met so plainly and fairly by "G. H.'s" reply (p. 90), "What can equal in grace and beauty a fine spray of *Odontoglossum Alexandre?*" Are not flowers that can be had in bloom all the year round most valuable, and with the many species in cultivation one is never without some bloom? And then, too, the lasting qualities of many species is another very strong point in their favour. The long continued pleasure that the richly perfumed blooms of a *Cattleya citrina* or the *Hyacinth*-scented *Zygotepalum Mackayi* give for so many weeks is not equalled by that of any stove or greenhouse plant. I should like to know which are the ten varieties "W." considers worth growing. I have been growing ninety, species chiefly, and varieties, and recently found that I needed a few more to add to my list. Now one word as to the cost of producing them. With such large importations as

Bolles celestis. Engraved for THE GARDEN from a photograph.

6 inches to 12 inches long and 2 inches broad, have a broad, sheathing base, and are bright pale green. The flowers, which are some 4 inches across, have violet-purple sepals and petals, tipped with white, more or less intense in the case of different plants, as the species appears to vary considerably. The lip, which is very peculiar, has a recurved margin, and is rich, deep violet beyond the middle, with a yellow disc; the front portion is plaited, and the large column is deep violet. These flowers last several weeks in perfection, and their rare colour renders them most desirable additions to summer-blooming Orchids. *B. Lalindei* in habit of growth resembles the last-named species. Each peduncle bears one flower, about 3 inches in diameter. Its sepals and petals are lilac at the base, passing into pale rose and tipped with pale yellow; the lip is golden yellow; the column rose colour, but in some forms the lilac becomes violet, and the lip orange-yellow plaited in front. It blooms about midsummer or early in autumn. *B. Patini* has flowers upwards of 3 inches in diameter; their

them; viz., the trade. I now turn to "J. D.," who says the culture of Orchids is easy enough to one who "knows anything" about plants, a statement which he will get no Orchid grower of experience to endorse, and which is contradicted by every-day examples all over the country. I say, without fear of contradiction, that in ordinary places where the stock is not kept up by the constant introduction of fresh plants, the condition of most collections is wretched in the extreme. "J. D." contradicts himself before he gets to the end of his remarks by stating that no one will be successful in Orchid culture "who does not personally minister to the wants of his plants, or has someone else to do it for him," a statement that conflicts with that just quoted. He has not even "patience," he tells us, with those whom he has often heard remark that Orchids can be grown "without any care or attention bestowed on them."

Neither of your correspondents approach the subject from the right point. Since, however, they have voluntarily taken up the opposite side, will they go further and tell us what their collections of Orchids have cost them? how much they are

are made every month and week, the prices have come down now so as to be within the reach of any grower and buyer of stove and greenhouse plants, and, as "G. H." so plainly puts it, the increase in value of a carefully selected and well-grown collection is a point which to many may be of interest and importance. Instead of Orchids going out of fashion it would seem that the reverse is the case, as in every direction one hears of a considerable interest being awakened amongst growers of these beautiful flowers, and also of many who are now commencing to cultivate for the first time a class of plants interesting from so many points of view.—J. T. P.

SHORT NOTES.—ORCHIDS.

Lycaste Skinneri.—We saw this week one of the finest dark forms of this Lycaste that have yet come under our notice. This variety has flowers about 7 inches across, and is now in bloom at Devonhurst, Chiswick.

Oncidium Cebillei, which is said to be scarce in collections, may now be seen in flower at Devonhurst, Chiswick. The labellum is bright canary-yellow, and the sepals and petals irregularly blotched with chestnut-brown.

Cattleya chocoensis is now finely in flower at Ginnerbury Park. It is a useful winter-flowering Cattleya, and one which should be in all collections. A very fine form of *L. anceps Dawsonii* may also be seen in flower now at Ginnerbury.

White Lycaste (*Lycaste Skinneri alba*).—We recently observed a remarkable form of this plant in Mr. Bull's nursery, the flowers of which are larger and purer in the waxy whiteness of their sepals and petals than those of any other which has previously come under our notice. This white form is very lovely when contrasted with the deep-coloured varieties now so plentiful.

Odontoglossums at Southampton.—From Mr. Bechem's collection come flowers of the beautiful *O. Krameri*, which blooms profusely there; also grand examples of *O. hastifolium*, its zebra-banded sepals and petals and varnished lip rendering it always conspicuous and ornamental, whilst the beautiful waxy snow-white flowers of *Odontoglossum pulchellum*, stained with yellow on the lip, are in great demand for bouquet-making.

Sophrontis grandiflora.—Great numbers of this brilliant scarlet flowered Orchid are now in flower in various places round London, notably in Mr. Bull's nursery at Chelsea; in that of Mr. Laing, at Forest Hill; and at Mr. Southgate's garden at Streatham. It is a plant of easy culture, often thriving admirably in a Wardian case along with Ferns.

Cypripedium norphyreum.—A very good form of this hybrid Lady's Slipper is now in flower in Mr. Bull's nursery at Chelsea. It is the result of a cross between *C. Roezli* and *C. Seidmi*, and somewhat resembles *C. Seidmi*, but is superior to that variety. Its pouch-like lip is deep rich crimson, beautifully shaded with porphyry. The richness of its colours and its being a winter bloomer make this variety a decided acquisition.

Lycaste Skinneri.—Numbers of forms of this fine winter-blooming Orchid are now in flower at Wilton House, Southampton, the residence of Mr. Bechem; their colours range from the purest white, through various shades of rose and rose red to the deepest crimson; scarcely two plants produce flowers exactly alike. This is an easily grown Orchid, succeeding even as a window plant, and it may be depended upon to produce its beautiful, large, waxy flowers about this season of the year under such conditions as would suit a Fern or a Pelargonium.

Cypripedium Amesianum.—This new hybrid Lady's Slipper is flowering in Mr. Williams' nursery, Holloway. It is the result of a cross between *C. insigne* and *C. villosum*; the upper sepal is white, veined and netted with green, and stained towards the base with brown; the petals are large, bright chestnut-brown in the upper part, the lower half being paler; the lip is large, brown, passing into green in front, and the whole flower has the same varnished appearance which is such a conspicuous character in *C. villosum*.

Odontoglossum crispum apiatum.—This, perhaps the most beautiful of all the varied forms of this popular Orchid, is now in flower in Baron Schroeder's collection at The Dell, Egham. Its flowers, which are large, are remarkably round and full, the white sepals being spotted with rich brown, whilst the spots on the petals are very large and of the deepest crimson. The lip, which is pointed in front, is spotted with brown, into which runs the golden yellow of the crests, making altogether a grand flower.

Lady's Slippers at Forest Hill.—Numerous forms of these are just now a conspicuous feature in Mr. Laing's nursery; the most noticeable are *C. villosum*, with its large pale chestnut-brown flowers; *C. Boxalli*, which is nearly allied to it, but differs in having the upper sepal broadly margined with white and spotted with black; *C. Seidmi*, with its rich crimson pouch-like lip, may be justly termed a hybrid perpetual, for it is nearly always in flower; *C. Spicatum*, with its pure white upper petal, is ever beautiful, contrasting well with such kinds as *hastifolium*, *Harrisianum*, and *Muleri*; the flowers, moreover, last a long time in water; some out on New Year's Day are still fresh and bright as ever.

Angreum sesquipedale.—A plant of this *Angreum* at present in bloom here has two blossoms measuring 6 inches across, and the lips are 13 inches in length. I can-

not think that the above dimensions are often exceeded in England, or that in this country the plant ever really merits its designation of sesquipedale (1½ feet).—C. H. F. Strand.

We do not think your measurements unusual, having frequently seen the flowers of this *Angreum* 8 inches and 9 inches across, with the spur 13 inches and 15 inches long; and on a few occasions we have seen the spur 18 inches in length, but we think this length is seldom seen in this country.—LIV.

Odontoglossums.—I have a small house in which I wish to grow *Odontoglossums*, but cannot get the temperature as low as required, as there are two 2-inch hot-water pipes leading through it to a house beyond. The temperature at present keeps at about from 50° to 55° at night, which I find rather too warm for cool Orchids. I have done *O. cirrhosum* and *hastifolium* very well; what other *Odontoglossums* require more warmth than the coolest ones?—OYST.

* We should think *Odontoglossum Roezli*, *Roezli album*, *Kramerii*, *Gerstedii*, *Phalenopsis*, and *vexillarium* would thrive well under the conditions you mention.—E.P.

HYBRIDISING ORCHIDS.

BOTANISTS of the last century had a singular dislike to the work of the hybridist. Lindley said by this art, "All ideas of species and stability of structure in the vegetable kingdom would be shaken to their foundation." The object of the hybridist is to improve the plants or flowers which he manipulates, and he chooses the seed and pollen-bearers accordingly. Orchids, which at one time were thought to be beyond the power of the hybridist, have been found to be amongst the easiest of plants to fertilise. When I first began to cultivate Orchids I was anxious to obtain a plant of *Cypripedium Harrisianum*, at that time the only English raised hybrid in the trade, but it was too expensive for us. Its parents we had. I crossed them both ways, and obtaining seed-pods, which ultimately produced plants; these we now have, and they are very large specimens, which annually produce a plentiful supply of bloom; they are also very varied both in form and colour. All large-flowering Orchids, such as *Cattleyas*, *Cypripediums*, *Cymbidiums*, *Dendrobiums*, &c., are easily hybridised. The pollen masses may be detached with a pointed stick, and can readily be applied to the parts of fructification behind the column. The pollen is attracted by the sticky mass thereon, and it is not necessary to remove the pollen masses from the flowers operated upon. The least difficult part of the work is the production of good-looking seed-pods, which will ripen in various periods of from three to twelve months. If the seeds are good they will vegetate in time, but there are probably only one good seed in thousands; and even if the seeds are good the conditions necessary for their germination may not be quite perfect. It requires patience to wait for the germination of the seeds, and even after the tiny plants have been formed, it is grievous to see the way in which they disappear one after another. As a rule, the best place to sow the seeds is on the surface of the peat or Sphagnum in which the parent plants are growing, and the surface must not be disturbed until the young plants appear. I sowed some seeds two years ago, and the plants were so long in coming up that it was thought they would not vegetate at all. The old plants were therefore potted, but, contrary to expectation, a number of seedlings came up in a few weeks. It may be as well to state that each seed-pod contains thousands of seeds, but only a few plants may be raised from them. In the case of *Phaius irroratus*, one plant only arrived at the flowering stage. When the little plants have once been potted off and established, they are practically safe, and they pass well through the winter in small pots if placed near the glass. Every cultivator of Orchids may be a raiser of seedlings. J. D.

Oncidium andigenum.—We have received from Mr. Osborne, Wilton House, Southampton, a handsome flower, which he describes as his best form of *O. Phalenopsis*, but which appears to be identical with a flower which we received from Mr. Bunneman last year, and which Professor Reichbach had named *O. andigenum*. The sepals and petals, which are creamy white, are profusely, but irregularly dotted with purplish crimson, and the petals are much broader than the sepals. The lip is deeply lobed in front, the side lobes being large, white, heavily blotched and spotted with purple and ma-

gent. The crest is deep yellow, and the column pale purple.

ROSE GARDEN.

T. W. GIRDLESTONE.

STANDARDS AND THE SNOW.

Now that the snow is gone, it is possible to estimate exactly the damage done among the standard Roses by the strangely sudden storm, which must have dashed the hopes of so many intending holiday-makers on Boxing Day. The storm was very similar to the one that occurred last winter, the snow coming after heavy rain, and falling, as it were, in great lumps rather than flakes, adhering thus in half-thawed masses to the wet trees and shrubs, where it was suddenly fixed firmly by a hard frost. The high wind then waving the branches about, laden, as they were, with heavy weights of frozen snow—weights which were all acting on levers of various lengths—naturally enough wrought sad havoc among the trees, especially the Evergreens and Conifers, and trees with wide heads and narrow stems, such as standard *Rhododendrons* and standard *Roses*. Of these last, the ones which came through the ordeal best were those which had been specially staked with a view to their protection in case of snow, and the next best were those which were not staked at all, or had broken away from their supports. The bulk of the damage was done among the standards that were staked in the ordinary way, the chief victims, of course, being those with the largest and handsomest heads, including many specimens of the Tea-scented varieties, whose spreading tops afforded additional lodgment to the snow from having fronds of Bracken twisted in among them. These tops were broken down chiefly near the point of union of stock and scion; but the un-staked standards saved themselves by bending before the storm and burying their heads in the snow, and comic enough they looked in the morning, as if their stems were playing at being croquet-hoops. A few were not pliant enough and broke in the middle, but their discreet humility was the means of preserving the majority intact, and careful binding and staking will, no doubt, restore even the cracked ones.

The special staking above referred to consisted in providing each plant with three stakes, in addition to the one to which the stem was secured in the ordinary way, these three stakes being long enough when inserted firmly in the ground to extend above the top of the head of the standard. They were placed about a foot from the stem, so as to form the three points of an equilateral triangle about the plant, and to them the head was firmly secured. This arrangement was found completely successful in supporting the trees uninjured, in spite of their burden of snow, and was adopted for the preservation of some large-headed Teas which had been damaged by the snowfall of the previous winter. Of course this mode of securing the safety of standards could not be very extensively or generally made use of, but it is always worth while to bear in mind that in the case of standard Teas the loading of the heads with fronds of Bracken as a protection against cold largely increases the danger from wind and snow to which these Roses, owing to their spreading habit of growth, are especially liable; and, considering that some Teas and Noisettes make the most beautiful because the least formal of all standards, it cannot be held that they are not well deserving of a little extra precaution and trouble to preserve them from destruction.

The argument that standards being liable to so many ills should be discarded in favour of

dwarf plants hardly applies in these cases, for though it is undoubtedly desirable that the bulk of a collection of Roses should consist of dwarf plants, still there are in most gardens some positions where standards may be effectively placed, such as at the back of large groups or beds of dwarf Roses, when the standards raise the level of the group behind without their own bare stems being obtrusively conspicuous. If standards thus utilised are broken down and destroyed, their loss cannot be at once made good, for their decorative effect depends upon the development of several years' growth, and consequently, as the larger they grow the greater the risk they run of breakage by wind or snow, it is important that during the winter preventive measures be adopted to ensure the safety of these as it were specimen standards, more especially when they are of Tea-scented varieties or Noisettes.

It is possible, by the selection of compact-growing kinds, to have small-headed standards, which are practically secure against even a combined attack of snow and wind, and which may be very well employed to break the monotony of a flat surface of dwarf plants; and no Roses are more charming for such a purpose than the miniature Hybrid Polyantha. Two years ago a large bed of Moss Roses, in which numerous sorts were grown with their shoots pegged down horizontally all over the surface, was considered to look rather dull, both in spring when the surface appeared too uniform, and in autumn when there were no flowers; the experiment was tried of dropping in irregularly among the Mosses several standard plants of the pretty pink-flowered Polyantha Mignonette (Guillot, 1882), and, as is said to be the case with all patent medicines, "they afforded immediate relief." The bed lay in front of a hedge of common Holly, and the effect of the little bushy heads of clustered rosy flowers, about a couple of feet above the general level of the fresh young growth of the Moss Roses, and backed by the deep green of the Holly, was very pleasing; and as, in spite of being in flower before the Mosses, Mignonette was still furnishing fine trusses at the end of November, the difficulty of a want of autumnal bloom in the bed was also met. Moreover, owing to their compact habit of growth, none of these standards with their heads about a foot high and a foot through, were injured by the snow of the last two winters, and even if in more exposed situations they were in any danger, they might be made perfectly secure by having a stake rather taller than the entire plant, and being tied firmly round the head as well as round the stem.

There are, doubtless, many other Roses more or less fitted by their habit to resist winter damage, which might be named were there any object in multiplying instances; but the above cases will serve to show that it is, at any rate, a possible course, in planting standard Roses where they are not thought worthy of the trouble and means requisite for their efficient protection, to select varieties which are not very liable to be broken down by snow, even if accompanied by a gale of wind.

The Roses after the snow.—Once more after a month's absence our dwarf Roses have reappeared, and, so far as the symptoms go at sight, they are none the worse for their living burial under the snow. Neither have they been idle. Not a few of their buds have advanced from sheer dormancy to the bursting point, and many of the more excitable have even got beyond the latter. It was interesting to note the varying sizes of the thaw lines around the collars, indicating how the heat of the plants had assisted the returning warmth of the air in getting rid of the snow. But the most pleasing fact of the Rose season so far is, that the snow has proved a perfect boon to all the Roses

that it covered. How far that covering over from the light as well as the cold may render the plants more tender and susceptible of future injury is quite a different matter. However, so far nothing could have been more suitable than the weather we have had since the snow has departed for gradually inuring the Roses to light and air, and thus preparing them for any hardships that may be in store for them.

STANDARD ROSES BEST IN TOWNS.

THERE is considerable prospect that as the standards diminish in the country they will increase and multiply in towns. Several causes are at work in this direction. Probably the more potent among these are the annual clearance sales that abound throughout the autumn in most of the more important provincial towns throughout the kingdom. Enormous quantities of standards are offered week after week on every market day from the middle of October to the end of November. The qualities of the consignments vary from the very best to the worst, and prices have a tendency to sink to very low levels—indeed, 1d. per plant being common enough. Such prices prove a powerful temptation to everyone with a garden in the country, or a yard of ground in or near a town to try Roses; the cost is so little, that should they fail it is of little moment. Thus thousands have tried to grow Roses at 1d. or 2d. each that would never have attempted it had they averaged 1s. or 1s. 6d. Thus which has proved a heavy loss to the trade has not seldom brought pleasures new and sweet to town and suburban gardeners, and given a powerful stimulus and a wide extension to the culture of Roses.

Fortunately, too, those much-abused standards that have been almost given away in these provincial markets have proved the most suitable material for those cribbed, cabled, and confined fragments of ground shut in and out from sun and air in the front, back, and side gardens of towns and their suburbs. To plant dwarf Roses in such dark, dank spots is to virtually bury them alive. The air is hot, stagnant, foul; the soil, too, is often dead. The latter may be improved, changed, and the best put in the place of the worst; but the air is unchangeable up to the line of the closely enclosing walls. Above these there may be, there possibly is, soot and dust, but there is also motion. The difference the latter makes is incalculable; in a word, the motion makes all the difference between the life and the death of Roses.

I have lately met with some striking examples of the difference to plant life and health under and above the wall lines of some back court gardens in London. Various shrubs, including Hollies, Lilacs, Aucubas, Laurustinus, and others, were planted. In general terms the whole of these under the wall line are bare at bottom or dead, while above the lines of the many walls, most of these, including a Rose here and there, are alive. But the chief point, and it is on this that I invite the free planting of tall standard Roses in town and suburban gardens, is, that the taller the plants the healthier, as a rule.

In the reticulated network of garden plots under the walls few shrubs but Ivies, Euonymus, Aucubas, Periwinkles, and Virginian Creepers seemed able to survive. Another mode of providing Roses for town and suburban gardens is even more sure and effective than the planting of any number of standards, short or tall, though it is far more costly. This consists in the purchasing of well grown, thoroughly ripened plants of *Maréchal Niel* or other free blooming Roses, and either plunging them over the rims of the pots, or planting them out, and expecting them to bloom but once. They may then be removed, sent back into the country, and grown again into blooming strength and size, or thrown away. By thus treating Roses as annuals, really good blossoms may be had in most town and suburban gardens. And as to the cost, there are few investments that will yield more pleasure in less time than an

annual investment of a few pounds for Roses warranted, from their vigour and maturity, to flower fairly well once under the most unfavourable conditions. D. T. F.

EFFECT OF FROST ON ROSES.

ALREADY it is evident that the late severe frosts have left their mark on standard Roses. Those that were in the best health appear to have escaped uninjured, but all that were weakly have been killed outright. It is the stock that is the first to suffer, and, as far as I am concerned, the days of the Brier stock are numbered; to dwarfs or bushes we must trust for the future. Unfortunately, the *Manetti* is very short-lived with us, many never recovering from the check sustained in their transference from the nurseries. Own-root Roses are what we require, and these are being rapidly increased. We propagate them as we do Gooseberries, &c., take off the cuttings in November, and at once dibble them into the open ground. They strike without any extra trouble being taken with the soil in which they are put, but all the better if a liberal addition of road grit or river sand is mixed with it, and they also move better. Last season fully 90 per cent. of the cuttings made strong plants during the summer. We are now transplanting from three long rows of plants numbering not less than three hundred, or sufficient to fill up all blanks and also to form a fresh bed. The sorts most easily struck are John Hopper, Countess of Oxford, Charles Lefebvre, Gloire de Dijon, Souvenir de la Malmaison, Baron Gonella, Etienne Levet, Cheshunt Hybrid, Dupuy Jamain, Boule de Neige; we have also rooted a good percentage of Francois Levet, Anna Alexieff, Dr. André, Baroness Rothschild, Elie Morel, White Banksian, Alfred Colomb, Marie Baumann, Captain Christy, La France, General Jacqueminot, Charles Darwin, and Dr. Hogg. If given plenty of room the rows being from 12 inches to 15 inches apart, and the cuttings not less than 9 inches a-under in the rows—they make good plants the first summer; many of them indeed flower freely, and they would do still better but for the almost certain prevalence of mildew.

It is now too late to insert cuttings of Roses in the open ground, but they may yet be struck under a north wall, and here let me add that it is from well established dwarf Roses that we obtain the greater portion of suitable cuttings. The preference is given to well-ripened growths, which are shortened to 1-foot lengths and cut to a joint, the lower buds and thorns being trimmed off. They are then at once firmly inserted to half their length, and in the case of the November-made cuttings a mulching of straw manure is all that is further needed. Those put in early in the year frequently do not callus properly before top growth commences, and failure is the inevitable result. Placing them in a cool position materially checks the bursting of the buds, and thereby increases the chance of a good strike. In order, however, to leave nothing to chance, it is advisable to examine some of them directly top growth appears imminent, and if they have not callused all the forward buds should be rubbed out, for it is certain that if the stored-up sap is expended on top growth there will be no roots. Once the roots are started there need be no fear of any delay in the top growth, as all these buds rubbed out will be followed by two others, one on each side, and which probably would not have started had not the more prominent central shoot been rubbed out. It is not to be expected that cuttings put in during January will develop into such strong plants the first year as they would have done had they been inserted in the open during November, but all that strike are hardy and useful own root Roses.

TEA ROSES, if strong, well-ripened cuttings can be obtained, may be struck in a similar manner to the Hybrid Perpetuals; those obtained from strong pot plants or from plants under glass are the best for the purpose. Most of our Teas in the open or planted against walls were obtained from cuttings struck in heat early in the year, and kept growing

freely in pots till the following spring. Strong, healthy plants in pots flower freely during the winter and spring months. Every shoot from which a bloom has been cut is suitable for making into a cutting. This should be done before it has made any fresh growth, and should be shaved off neatly from the old wood—a heel thus obtained being more likely to emit roots than an ordinary cutting. Most of our cuttings are about 3 inches long, and have two or three healthy leaves attached to them. Weakly shoots are of little use, the foliage frequently dropping early, and no roots are the consequence. They strike most readily in 2½ inch pots, filled with gritty loam, one cutting being firmly bedded in the centre of each pot; these are plunged in a gentle bottom-heat, and covered either with a shallow frame or handlight. They must be shaded from sunshine, and should never be allowed to suffer from want of water. In our Cucumber house, plunged in the bed of leaves and stable manure on which the Cucumbers are started, Rose cuttings strike frequently in less than three weeks, and soon fill the pots with clean, healthy roots. They are not allowed to become stunted in small pots, such treatment having caused the loss of thousands of newly-struck Roses; they are gradually shifted into 8-inch, and even larger, pots, and in the spring, after they have perfected a few fine blooms in a light and cool greenhouse, they are planted out in well-prepared soil. That popular Rose *Marchal Niel* may be rapidly increased in the manner just described, none striking root more readily than it does, and when planted against sunny walls it frequently forms extra long and strong growths. These, if carefully supported and given an easy curve, will, the following season, develop wonderful fine blooms at nearly every joint.

W. I.

PROPAGATING.

SHRUBS.—A ready way of increasing many shrubs, and one for which no frames or other appliances are necessary, is when shifting operations are going on to detach any rooted suckers or branches that may have been buried deeply, and thus have formed roots on their own account. The pieces in question must be separated from the parent plant as carefully as possible, and planted in a nursery quarter, or in some spot where they will receive attention till established. Of course this method can only be employed for certain classes of plants; those that do not send up shoots from the base cannot be operated upon in this manner, but such as *Spiræas*, *Cydonias*, *Philadelphus*, *Berberis*, hardy *Heaths*, and many others, will, if carefully examined, yield a greater or lesser number of young plants. Many shrubs that do not send up shoots from the bottom may, however, be induced to root in this way if planted deeper than usual, but this is to a certain extent a modification of layering, which is available in a greater or lesser degree in the case of most trees and shrubs. By means of layering, many subjects that cannot be struck from cuttings are increased, and this method possesses one great advantage, inasmuch as larger branches can be induced to root from layers than by means of cuttings, while a corresponding drawback is the fact that layers take longer to form plants than cuttings. Layering pure and simple can be carried out at any season, the principal requisites being a strong knife, stout hooked pegs, and a spade to loosen up the soil. In selecting a branch to be layered, the principal points to be observed are the readiness with which it may be brought in contact with the earth, the number of plants likely to be obtained from it, and which portion can be operated on without disfiguring the parent plant, that is, provided it is grown for ornament; in nurseries where plants are increased in this way, the parent plants known as stools have all their branches layered in the form of a circle, and by the time they are rooted sufficiently to be detached, other shoots have grown up in the centre to be treated in the same way in succession.

CHOISYA TERNATA, which within the last few years has attracted a good deal of attention, is by no means difficult to strike from cuttings, yet one or two points, as regards the operation, require to be carefully considered. The best cuttings are the young shoots, just as they have attained full dimensions and before they have become woody. In a general way, the entire growth is about 4 inches long, and if that is cut off just at its base, and the bottom leaves removed, the cutting is then ready for insertion. For their reception take some 4-inch or 5-inch pots, fill them to about one-third of their depth with broken crocks, then put in the soil, and press all moderately firm. Space should be left on the top for about a quarter of an inch of silver sand. The soil most suitable for the purpose is about equal parts of loam, peat, and sand, the whole being passed through a sieve with a quarter of an inch mesh. In dibbling in the cuttings care must be taken not to put them in too thickly, and they should be kept as near the edge of the pot as possible, contact therewith accelerating the formation of roots. After being thoroughly watered, they must then be put in a close propagating case or in a close frame on a hotbed, when they will soon root, and may then be hardened off. Two points to be observed are not allowing them to flag, either from want of water, or too much sun or air; and keeping a sharp look out for thrips, which increase rapidly in the close atmosphere of the propagating house. In the case of plants growing in the open ground, the cuttings will not be in a proper state for insertion till much later in the season, but the same instructions will apply to them, except that they will root if protected by a cold frame. However, a great advantage belonging to early propagation is the fact that the cuttings will be struck and well established as young plants before winter sets in.

LUCULIA GRATISSIMA.—This is another plant that, like the *Choisya*, many fail to strike in a satisfactory manner from cuttings, yet I have propagated great numbers of it, and have never experienced any difficulty in the matter. After flowering, if the plants are shortened back slightly and a genial atmosphere maintained, they push forth new shoots freely, and if these are taken when half ripe—that is, after they have lost their succulent character and before they have become woody—no difficulty will be experienced in getting them to root. We have a propagating case arranged in a cool part of the stove, and in it the *Luculia* cuttings are placed and plunged in a gentle bottom-heat. They, if possible, consist of the entire shoot, cut cleanly off just at the base with a sharp knife. However, if the shoots are of a greater length than 4 inches or 5 inches, the cuttings must be made of the upper portion of the shoot, as if too long they seldom produce roots. The soil, which should be of an open character, should consist of about equal parts of peat and sand, with a little admixture of loam. The cuttings are best put singly in 2½-inch pots in the soil just mentioned, finishing off with just a little sand on the top. No more leaves must be taken from the cuttings than is absolutely necessary. After being watered and plunged in the case, the after-treatment consists in shading, watering when necessary, and in taking off the lights every morning to dry up superfluous moisture, removing at the same time any decaying portions. One thing to bear in mind is, that the weaker shoots strike root more readily than the very vigorous ones.

FINE-FOLIAGED STOVE PLANTS of a herbaceous character may now be divided, if need be, for propagation, *i.e.*, such as *Marantas*, *Alocasias*, *Anthuriums*, and similar subjects, some of which have been rested during the winter. The soil must be shaken from their roots, and after division to the extent required, they can be again potted. In the case of any that have little or no roots attached thereto, they are all the better if kept close till root action re-commences. In all cases an open compost, consisting principally of peat, Sphagnum, and sand, is most conducive to the rapid formation of roots. In the case of many of

the *Alocasias* there are often small tuber-like masses attached to the roots, which, if cut off and potted, will in time push up leaves, and finally become established plants. T.

Raising hard-coated seeds.—“A. D.’s” successful experience in the raising of *Lathyrus Drummondii* from seeds proves that all kinds of flower-seeds are easy to get up when one knows the conditions that suit them. The seeds of this *Lathyrus* are, I think, harder than those of any other plant, *Cannas* excepted; and although I gave them the conditions that I have never found to fail in the case of hard-coated seeds generally, I did not get one up. Sowing as soon as ripe seems to be in their case, as it is in that of many hard-coated seeds, such as, for instance, those of the *Christmas Rose*, the secret of success. I have just examined some pots of the white *Everlasting Pea* that I sowed in October, and the surface-soil is, I see, studded with little blade-like growths, which show that it is amenable to this kind of treatment. This *Pea* comes up fairly well in the open ground if sown in March, but the soil must not get dry while the seeds are germinating. By sowing in the autumn, however, one gains several months. Young plants in growth now will, if put into good ground in April, be sure to flower the following year; whereas a second season will be needed if sown in the open ground in spring. I do not think there is any other way of getting up the seeds of tuberous-rooted greenhouse *Tropeolums* except by sowing as soon as ripe. I have raised hundreds in this way, the young plants appearing at the beginning of autumn.—JOHN CORNHILL.

GARDEN FLORA.

PLATE 582.

LEWISIA REDIVIVA AND MICROMERIA PIPERELLA.

(WITH COLOURED ILLUSTRATIONS.*)

AMONGST plants which arouse the curiosity and wonder of the cultivator, perhaps none is more remarkable than the *Lewisia* figured in the accompanying plate. Like many of the fleshy-leaved *Gasterias* and *Aloes*, it seems to protest loudly against being dried and laid aside; indeed, it is on record that specimens of it, after having been preserved in a herbarium for two or more years, have kept sending out fresh crops of leaves. The specimen figured in the *Botanical Magazine* (t. 5395) is said to have been one of many gathered with the view of being preserved. It was immersed in boiling water on account of its well-known tendency to revive, as its name indicates, and even after a lapse of eighteen months it showed signs of growing; one specimen produced flowers at Kew in 1863. Under the name of *Spatulum*, or *Spatlum*, it is used as an article of food among the natives of North-west America. The bark is stripped off and the white portion of the root left is boiled, when it forms a substance somewhat akin to arrowroot. Although in the herbarium it shows an extraordinary tenacity of life, when grown in the open air it requires, during the winter season at least, great care on the part of the cultivator. Under suitable conditions, we have found it hardy enough to withstand severe frosts; but it is very susceptible of damp, and the heavy rains that are so prevalent at that season should be rigidly guarded against. Our plan is to choose a well-sheltered spot exposed to full sunshine, drain it thoroughly, make it porous, and raise it considerably above the surrounding ground. This necessitates more than ordinary care in the way of watering in summer, but a little care bestowed in this way

* DRAWN FOR THE GARDEN IN MESSRS. BACKHOUSE'S NURSERY AT YORK BY THE LATE MR. NOEL HUMPHREYS.

will be fully repaid by a grand display of magnificent flowers. This *Lewisia* seems to prefer limestone; therefore we mix plenty of old lime rubble with the soil, and, thus treated, it never fails to produce an annual crop of blooms. Its summit or crown scarcely rises above the ground, and it is surmounted by numerous round, smooth, glaucous leaves, about an inch or so long. The flowers are produced from the centre of the leaves on short stalks jointed beneath the calyx, and bearing a circle of small imbricated bracts. The flowers, which are from $1\frac{1}{2}$ inches to $2\frac{1}{2}$ inches in diameter, are composed of from twelve to fifteen petals; the calyx, as may be seen, is also singular. It makes a handsome pot plant, each of the flowers lasting two or three days, and a dozen or so are often produced in succession. It blooms in May and June. It comes from Oregon, near the mountains, where it is found on dry prairies, adjacent to rivers. There is also a form with white flowers. *L. brachycalyx* is a new species not yet introduced to our gardens, and perhaps inferior in point of beauty to that which we already have. Its leaves are spatulate or narrow linear, the flower-stems not jointed, and the flowers having only from seven to nine oblong petals. Both are now placed in the Order *Portulacaceae*.

MICROMERIA PIPERELLA.

M. PIPERELLA, or small Peppermint, as it is usually called, belongs to a genus of Labiales containing about fifty species, many of which are undershrubs, but a few of them are annuals, and, with the exception of the above and one or two others, of comparatively little value for our gardens. They are nearly allied to the well-known Thymes, also to summer Savory and Calamint, from which they differ in a few minute particulars almost microscopic. *M. Piperella*, however, we find to be a useful plant for the rock garden, where we find it to be perfectly hardy, and during the autumn months covered with a profusion of purplish pink flowers. It is plentiful in the Maritime Alps, the mountains near Mentone, but never at a lower elevation than 3000 feet above the sea. Early in October about Mentone this small Peppermint may be found at its best, and I am told that it is so plentiful there in some stations, that the effect produced by it is very striking. It seldom attains more than a height of about 6 inches, its flowers being intermixed with its leaves almost to the base of the stem. It is propagated readily by means of cuttings taken off about the beginning of August or later, and kept in a cold frame through the winter. D. K.

Humboldt's Bladder-wort (*Utricularia Humboldtii*).—This fine richly coloured Bladder-wort was first discovered, but not then introduced, some half a century ago, by Schomburgk, on the Roraima Mountain, on the western boundary of British Guiana, at an elevation of between 7000 feet and 8000 feet. It has, however, recently been re-discovered in the same locality, and some plants of it have reached this country in a living state, although weakly. It is to be hoped that some of these plants have found a home in Sir Trevor Lawrence's garden at Burford Lodge, where the other members of this genus succeed so well. From an illustration of it which has been in our possession for some years, we observe that the flowers are produced several together—the introducer says from ten to fourteen—upon an erect spike, and that the individual blossoms measure some 3 inches in diameter, the lower part being plaited. The colour is a rich blue with a lighter centre.—W. H. G.

Sulphide of potassium (*Veto*).—Both samples appear genuine—one crushed, the other not.

Decorative purposes.—We should be grateful to writers if they would not use these words, which are so often written instead of simpler ones. We cut them out often, but when they come too thickly, some, alas! creep in.

FLOWER GARDEN.

THE OLYMPIAN MULLEIN.

This great Mullein is one of the largest and stateliest of border plants, commonly 8 feet high, the flowering part alone showing a mass of bloom from 4 feet to 5 feet high and 2 feet across. Though called a biennial, and probably in its southern home completing its term of life in two years, it is generally three years coming to maturity in this country. This is rather a gain than not, as the plant in the unbloomed state, with its symmetrically arranged leaves of pale grey-green velvet, is very handsome. The same whitish, velvety down clothes all its parts, and is a setting to the masses of light yellow flowers,

Verbascum olympicum. Engraved for THE GARDEN from a photograph.

so that the whole has a pale, cloud-like look when seen from a little distance.

Wintering Pansies.—Last winter showed me that if we are to trust to bringing Pansies safely through the coldest months we must afford them, if needful, some protection. Constantly saturated ground for many weeks, followed by keen frosty winds, forms the conditions under which Pansies succumb. The weather of last winter seems to be repeating itself this year, and if we get ten days' brisk wind from the east or north, we shall undoubtedly have heavy losses to deplore among the more tender of hardy plants. Frost alone rarely injures Pansies. It is the keen winds that accompany it that do the mischief. Choice named show kinds appear to be more susceptible of injury than fancy varieties, and if they cannot be wintered in frames, they ought to be planted in autumn where they can have a little litter

thrown over them during a trying time. This would in one way be the better plan to adopt with the general stock whether named or not, but, as every one knows, Pansies bloom best when planted in autumn, so as to get well hold of the ground before winter sets in. I should, however, certainly have more confidence in getting good blooms from plants lifted carefully with good balls about the middle of March than from those put into position in autumn, and which had borne unprotected the brunt of such a trying time as we experienced last winter. In any case, where Pansies are relied on for filling or edging flower beds in conspicuous positions, a reserve of plants should be kept to fill up gaps caused by losses in winter. Pansies kept in pots in frames for conservatory ornamentation will need looking to now; all decayed foliage should be picked off, and the surface of the soil should be cleaned. Air should be given on all favourable occasions, drawing the sashes quite off when there is no cold wind. Seeds for a late summer and autumn display may now be sown in warmth. The young plants must be hardened off gradually, and pricked off into pans; when large enough to handle they may be planted out by the beginning or end of May, and will make a good show from the end of July till late in autumn.—J. C. B.

TREE AND HERBACEOUS PEONIES.

I AM delighted to see the great interest that is being taken in my favourite flower. If Mr. Hole wanted a Gloire de Dijon on his grave, I would be happy if *Peony Elizabeth* were planted on mine. A few years ago it seemed impossible to get any information in this country about growing and propagating these Tree Peonies, and the only collection I ever saw of herbaceous Peonies was at Parker's, Tooting. All this is changed now, and Messrs. Kelway, who always anticipate the future taste, and have the knowledge, wealth, and patience to prepare for the future, have collected 200 varieties of Tree Peonies, which are being propagated in every imaginable way. At Langport, then, can a study be made of their methods of propagation, and I feel privileged in seeing a nursery garden in the winter when the real work is being carried on.

In *Paston's Magazine*, somewhere about the year 1857, there is a valuable translation of a Japanese work on Peonies, herbaceous and tree. Ito Ifui, a great Japanese gardener, hundreds of years ago, gives directions for growing the Tree Peony. After saying how careful you must be not to tread on the soil of your bed of Peonies, as the soil must be kept light and open, he says that you can raise the seed in a pot, and, I think, advises the slight cracking of it—the seed, not the pot. Here, at Langport, there are thousands of seedlings, but the seed does not generally germinate till the second year, and only those plants are going to flower this year for the first time which are about six years old from seed, so it is a slow process, though likely to well repay the raisers. Ito goes on to say that you can graft the Tree Peony on the herbaceous stock (by which he means *edulis* or *sinensis*) either by means of a slip-graft on the root, or by taking the upper root-stock which *sinensis* makes (in opposition to *officinalis*), and grafting, perhaps holding, on that woody substance. He also mentions grafting on the root of the Tree Peony.

So there are several ways of propagating Tree Peonies. Firstly,—You can raise it from a cutting. Ito gives a funny recipe for this. He says, take a *Caladium* root, pierce it with a twig of *Gardenia florida*; put the cutting through, just sticking out at the under side; puste up with clay on both sides of the *Caladium* root, and plant it. It will grow, and the *Caladium* growing keeps it moist till it begins to root. He also says that oil of *Camellia* fruit must be rubbed on the stem of old Tree Peonies to free them from Lichen and Moss. No doubt this is a sensible

way of getting old stems to break, as I once saw a hidebound Rose stock rubbed with oil, much to the benefit of the scion. Unwitting of Ito, who wrote, I believe, 1000 years ago, Messrs. Kelway are practising the same methods. *Paeonia sinensis* or *edulis* is their stock for root-grafting, and eventually the scion is buried, so that it makes its own root above the point of union. The Frenchmen use *officinalis* stock, and that is why so many Tree Paeonies imported from France turn into the common herbaceous *Paeony*, and why it is better to buy a plant from an English nurseryman who has already established in his nursery. This, then, is the second method.

Thirdly.—They are raising it from seed by thousands. The seedlings are now, this spring, coming into bloom, six years old. Perhaps steeping the seed in water, or cracking it, would be a good plan.

Fourthly.—By root-cuttings pulled off the bigger plants. Each of these has an eye close to the main stem, and can easily be detached. So prevalent is this peculiarity to the Tree *Paeony*, that even the roots of cuttings show this dormant eye, and could be pulled off to make young plants.

Fifthly.—There is the grafting on the roots of the Moutan, or Tree *Paeony*, which are long and lanky, and not tuberous at all. The Tree *Paeony* plants I saw at Mr. Gordon's, at Twickenham, fresh from Japan, are grafted on the Moutan root.

Sixthly.—Possibly one could take any bit of root-cutting, lay it in the ground, and it would eventually make a start at the lower end. This remains to be proved of the Moutan or Tree *Paeony*. It is well known that it is the case with all other *Paeonies*.

I know few plants of large size in the whole country, and shall be glad to hear of any, but where they are I have always noticed shelter from morning sun and high ground. The spring frosts of the valley kill the young buds, and the whole plant suffers. Moreover, the soil must be very deep, light and loamy for a plant to grow 10 feet high. The youngest cuttings make roots 2 feet long, and the large ones must have a proportionate amount of soil exactly under their roots. An old gardener told me the parings of his Tree *Paeonies* took root when thrown on a rubbish heap. There are giant plants of the Moutan and *papaveracea* at Highclere. They are rather too much exposed, but the flowers of the single kinds were 9 inches or 10 inches across last summer. Other big plants are at King's Weston, near Bristol, the seat of Mr. Napier Miles, and there is a huge bush of Moutan in Mrs. Abbot's beautiful garden, Abbots Leigh, near Bristol. If that lady would only give us some account of it, of its age and behaviour, I should be grateful. This is, again, on high ground, and I remember my friend, the late Zolok Stevens, telling us of some gigantic plants in his neighbourhood (Trenton) in a high garden exposed to the north. Depend on it, these plants will do well fully exposed to the north, but out of the early spring sun, which thrives their leaves only too quickly. If anyone has a large plant of Elizabeth, I should like to see it. Elizabeth! Elizabeth! will be all the cry now. But greater wonders are yet to be seen, and are growing placidly at Twickenham to astonish the Royal Horticultural Society. Mr. Gordon has there Japanese drawings of most astounding varieties—no yellows, but deep crimsons, maroons, carmines, purples, all but blacks, and single or semi-double whites of such exquisite beauty, that no wonder I have a craze for the plant. Still there are yet in Corea, China, and Japan varieties of which we have pictures

on Japanese screens and fans. These are small-blossomed, but striped, edged, and flaked in a wonderful way, and these small-blossomed varieties seem to grow far taller and lankier, and become almost pendent. Their manner of growth is so peculiarly graceful, that the Japanese have made them a favourite subject for decoration. Corea is probably the home of the Tree *Paeony*, and soon this country will be opened up. In Southern China the Tree *Paeony* will not properly ripen its growth, but every fancier has a large number of varieties brought every spring to the south from Northern China, and sent back at winter time. The probable reason why the very fine varieties of *Iris Kämpferi* and Tree *Paeony* have not been obtained from Japan before is that the finest kinds belonged to certain families, who would not part, just as old gardeners who grow *Pansies* or *Auriculas* in this country will not part with a plant for any money. This custom is being broken down; hence the magnificent collections of Tree *Paeonies* and *Iris Kämpferi* at Twickenham. I remember Maries told me of his great difficulty in getting the finest kinds of this *Iris* out of the Japanese nurseries; and a traveller told me that a Japanese, without a rag to his back or a son in his pocket, will own a sword worth £1000, and sell it for no money. I fancy I was the first to excite in *THE GARDEN* this literature regarding the Tree *Paeony*, which received so much support from Max Leichtlin, who gave us the names of all Siebold's introductions and of Fortune's, and a list of certain varieties which probably still exist in the private garden of the King of Holland.

As for herbaceous *Paeonies*, Messrs. Kelway are at the top of the tree. Mr. Barr has a fine collection, and also of the species; but at Langport there are 2000 named seedlings, double and single. For at last our nurserymen are beginning to understand that the public has taste, or is led by those who have taste, and wants no dictation from so-called florists, who dictate out of their own dogmatism the shape of the *Primrose* and the spots on the *Polyanthus*. Nature and selection are enough for us. Consequently here no seedlings are now discarded, as all the single and semi-double varieties find purchasers. So, too, might Mr. Bennett, of Shepperton, benefit himself and the public who have taste by saving semi-double golden *Roses* among his seedlings.

FRANK MILES.

Sunnyhill, Shirchampton, Bristol.

SHORT NOTES.—FLOWER.

Iresine Herbsti.—A sport from this well-known plant bids fair to become an acquisition for bedding. We saw this week some stock plants of it beautifully coloured. It originated about two years ago, and up to the present has maintained its true character.

Primroses.—Mr. G. E. Wilson, of Heatherbank, Weybridge Heath, sends us a little posy of pairing flowers, comprising several lovely blooms of common *Primroses*, including Scott Wilson, which is the nearest approach to a blue we have yet seen; also *Cydonia* Coma, bright and beautiful.

Variogated double purple Wallflower. This was known to exist in Ireland some years ago, but it is believed to be now lost. I never saw a double purple variety either with or without variegated foliage, but if it is still in existence I feel sure that many would like to possess it.—J. C. C.

Nelumbiums.—Mr. Newberry speaks (p. 65) of a *Nelumbium* having thorns. Of all tender plants I who have grown it, should say that it was the least thorny. *Theophrastus*, or somebody, is making a mistake. Perhaps the *Nelumbiums* grew among thorny plants at the river edge. There are no *Nelumbiums* in Egypt or Syria now. The nearest are on the Caspian, at the delta of the Volga. The sacred *Lotus* of Egypt, as anyone can see by looking at the sculptures and paintings, was *Nymphaea Lotus*.—FRANK MILES.

Two useful Primulas.—*P. obconica* and *P. floribunda* are two of the most serviceable *Primulas* yet introduced, for they are nearly always in flower; our stock, though consisting of quite young plants, has hardly been without flowers all winter; even now a plant of *P. floribunda* has six tiers of flowers on one stem. Seeing that a cool greenhouse and ordinary garden soil suits them, it may be truly said that

they are everybody's plants; both are readily raised from seed and if sown early in spring the young plants will flower in the autumn. J. C. C.

DOUBLE PRIMROSES.

"R. D.," in *THE GARDEN* (p. 65), has earned the thanks of all lovers of old-fashioned garden plants by his instructive notes on these, the very cream of border favourites. Like not a few good things, however, they seem to be becoming more tender and more scarce. Memory recalls them as plentiful here and there twenty years ago. In Scotland and the north of England fat patches of these double *Primroses* in from three to six varieties were often seen in the gardens of amateurs and of cottagers, and in larger gardens they were yet more plentiful. Among these, the Scotch Red, which I believe to be identical with the modern crimson-purple; the pure white, soft *primrose*, double purple, and double lilac were the most common. And in many districts these, and probably some other sorts, seemed almost as hardy as the single *Primroses*. This was especially the case with the lilac, purple, and white. It seems singular that while the common lilac appears to retain its hardiness and its popularity, most of the other varieties have almost disappeared from the open border. Two causes may have contributed to this result—the plants may have become more tender, or more valuable. It may seem strange, and yet true, to add that their enhanced commercial value may have increased their tenderness.

The extreme beauty of these double *Primroses* has started collectors and florists in pursuit of them, and these have potted them up out of the open for purposes of more rapid propagation. But once in pots, their great beauty and unique adaptation for the adornment of window-sills and gardens naturally arrested the attention of amateurs, more especially in towns and the suburbs of towns. Double *Primroses* were new to most of them, and were bought up greedily, and destroyed almost as rapidly, for no plants are less fitted by Nature for being frozen and baked alternately on a window-sill than a double *Primrose*. In this and other methods the pot culture of these charming plants, introduced at first for the double purpose of protecting them from extreme cold and of fostering their more rapid increase, has proved the means of their destruction.

I have nothing to say against pot culture as an aid to increase, and all that "R. D." so well states about the mode of potting, safe modes of storing in cold pits, soils, and methods of procedure will be endorsed by all who are conversant with the character and habits of the plants. But the permanent culture or retention of double *Primroses* in pots is quite a different matter, and is probably largely responsible for their scarcity in our gardens to-day. Their sale as pot plants to those ignorant of their character, habits, and wants seals the death-warrant of thousands of double *Primroses*; while the exciting and semi-forcing expedients employed on the root-stocks to quicken the ratio of increase of young plants to the uttermost, so weaken and demoralise these hardy plants as to disqualify them from standing alone on open beds or borders.

Double *Primroses* have therefore probably lost more than they have gained through elevation into pots. The finest collection ever seen by the writer had never passed through these trying ordeals for so many hardy plants. On the contrary, they were propagated and grown in the coolest part of the garden. A border was formed over a border originally made for Morello Cherries behind a north wall; the base of the border was therefore exceptionally cool and moist. Its constituents for the *Primroses* consisted of two-thirds of good yellow loam, with one-third composed of almost equal quantities of peat, leaf-mould, well-rotted cow manure, and silver sand. A good deal of importance was attributed to the purity of the sand, the purest Reigate silver sand being used, and pit sand with iron being rejected as injurious. One half of the plants were divided

every year for purposes of propagation, so that some of them were two years old. The time of division varied considerably with the season and the varieties, and was regulated by condition. Immediately the flowers faded, the division of those about to be operated upon was set about. The plants were taken up and divided into single pieces, retaining a portion of root-stock to each when practicable. But more importance still was attached to the appearance of young roots among or immediately under the lower leaves. The old roots when present were looked upon as merely bridging over a period of risk and danger till the new roots at the base of the leaves were further developed or strengthened. Deep and firm planting of the roots, crowns, or stem segments were the chief points. The soil was carried right up to the base of the new leaves, and often any excess of foliage and the smaller leaves were thinned off to facilitate deeper planting. Unless the weather was specially dry, no water was given after planting. A little silver sand, however, was placed around the stemlets at planting, and of course the plants were not allowed to wilt for lack of a dewing overhead, if neither rains nor dews came to prevent their flagging. But the chief danger to these plants is an excess of water at this stage; and it must be borne in mind that the plants are on a north border, under a wall 10 feet high. The firmer the soil, if not too wet, is thrust around the collars, almost the sooner as well as stronger will these double Primroses root. The only further attention from this stage is to keep the plants free of weeds and from drought, though the latter seldom injures them on such cool sites and soils as those here described. The best antidote in abnormal seasons is, not water, but a mulch of well-rotted sweet—that is, three or four years old—cow manure. This, with an addition of about a third of silver sand and another third of leaf mould, forms a most stimulating top-dressing for the older half of the plants, applied immediately after the first flowering. A very rich coloured variety of double Primrose, called indifferently the Claret and Port coloured, was grown with the above, and disappeared, so far as my experience goes, when that collection was dispersed a few years since. I have had the pleasure of seeing most, if not all, of "R. D.'s" varieties, and I do not think this claret is included among them, though I am well aware that soil, site, local climate, and culture exert powerful modifying influences on purple, red, and crimson Primroses, double or single. Has "R. D." ever heard of this variety?

HORTS.

Brugmansia suaveolens.—The most effective manner in which I have seen this beautiful and sweetly scented flower used is in Mr. Horrock's garden, at Mascalls, near Paddock Wood, in Kent. The plants are trained to a single stem, much in the manner of a standard Rose. They then form a wide-spreading umbrella-like head, and from this the flowers hang down in profusion. I have seen twenty or thirty in bloom at once. They are planted in a sheltered spot in the shrubbery, and after they have done flowering they are taken up, potted into large pots, placed somewhere where frost cannot reach them, and then turned out again in the spring when all fear of frost is over.—DELTA.

White Everlasting Pea.—I have grown this Pea for years, and have found it to come perfectly true from seed. I consider it to be one of the most lovely of climbers. I had it last year 12 feet high, and a sheet of snowy whiteness. I also have a plant of the white sort growing along with the pink variety, and find the seeds of both to come true. I had one young plant last year which bore only one bunch of bloom, and that was white, striped with pink. I hope it may remain fixed, as I think it may be new. Those I raised from the root were worthless; they gave so little bloom. These Peas are plants that repay liberal treatment.—MARIE, Co. Wicklow.

Narcissus (Ajax) cyclamineus (Haworth).—This quaint little Portuguese species of Narcissus

is now in flower here for the first time, and, although long ago figured in "Jardin du Roi" (1623) and in "Theatrum Floræ" (1637), is even to day very rare as a garden plant. Plant 2-3-leaved, 8 inches to 12 inches high; scape rather shorter than the leaves, 1-flowered; perianth reflexed, the divisions being a trifle shorter than the corona; flower tube very short, say 2 lines or so long; ovary swells rapidly as the flower fades, and is proportionately very large. The bulbs came in October last from Mr. Tait, of Oporto, and I have this day sent a complete flowering plant to Mr. Baker, of Kew, for a full description.—F. W. BRIDGER.

THE PINK STIGMA OF HELLEBORUS NIGER MAXIMUS.

It may perhaps savour of temerity to differ from Herr Max Leichtlin; but in his denial that the pink stigma is a natural characteristic of *H. niger maximus* I think he would find it difficult to maintain his position; and I should be sorry if he could; inasmuch as it is very desirable and convenient to have certain permanent and easily recognised marks to separate one group from another. Herr Max Leichtlin remarks that *H. niger altifolius* of English gardens has changed its original character in substance, time of flowering, shape, and in fact generally; that typical *altifolius* is not stout, but slender; has not a cup-shaped, but rather a flattish flower; that even under glass the flower is pinkish or rose-white, and that the pink colour of the stigma is produced by climatal influence. Now, in contradiction of this we have the evidence of Mr. Engleheart (THE GARDEN, Jan. 8, 1887, p. 22), who states that between Menaggio and Porlezza, in Northern Italy, he found a Hellebore, evidently *H. niger altifolius*, growing in a natural state, "flower large and cupped, pure white, with slight flush of buff-pink, noticeable for its pink stigmata and tufted yellow anthers." We have Mr. Wilks' authority (p. 49) that in the same locality one mountain-side was covered with *H. niger maximus*. He says, "I noticed some with leaf-stalks over 12 inches in height, and leaves like large Horse Chestnut leaves. I brought home two plants, one a bit off the very biggest I saw, flowers pure white touched with pink, and pink stigmata, the other a beautiful clear creamy pink," &c. So much for the plant in its wild state.

Next let us consider it under cultivation. Here, in ordinarily good seasons, it is a pure white flower, cupped, and 4 inches or 5 inches across, with large pink tipped stigma. No doubt, climate, or rather difference of position, shelter, or exposure, drought or rain in summer, frost, rain, and cold winds at flowering time, all have a marked effect on the quantity, quality, and purity of the flowers; this season especially on many plants the flowers are few, and from first to last as pink as, or even more so than, Mr. Ware's *niger ruber*. Last year, and generally, my flowers have been of the purest white, many of them not even tinted with pink on the under side of the sepals; the stigmata pink. I know of none so purely white, unless I compare them with some magnificent blooms of the Riverston variety (4 inches and 4½ inches across) sent to me a short time since by Mr. Hartland. (In passing, I may mention that he sent me also a very beautiful scilling of *H. niger* raised in his garden.) Herr Max Leichtlin goes on to say, "I wonder why any value is placed on a pink or green stigma, which is only produced by climatal influences, especially by often changing temperatures, which cause the flowers to become moist and dry alternately according to circumstances."

Now, no doubt these influences have an effect, but, in my experience, only to the same extent as in the case of the flowers. I have seen, under such influences, that even on the same plant, while the stigma of one flower retained its full pink colour, the stigma of another showed no trace of pink; but, as with the flower, so with the stigma, the change is only temporary; the characteristic is inherent and reappears; next season

the stigma is pink as usual. But may I ask if climatal changes, &c., produce a pink stigma in *H. n. maximus*, why does the same result not occur in *H. niger* type?

Everyone is aware that whatever skill could accomplish Herr Max Leichtlin would achieve, but that he could fulfil his engagement to produce *niger* with pink stigmata, or *altifolius* of English gardens with green ones, I more than hesitate to accept. I assume, of course, that in the trial the two kinds should be kept apart to preclude the possibility of crossing. I know of only four *H. nigres* with pink stigmata: 1, *maximus*; 2, Riverston; 3, Mr. Tymons; 4, Glasnevin. With the exception of *maximus*, we do not know the origin of these varieties, but having pink stigmata they also should be excluded from the trial ground.

South Devon.

T. H. ARCHER-HIND.

IMPORTED CHRISTMAS ROSES.

MANY thousands of the common Christmas Rose are annually imported into this country from their native habitats, and singular as it may seem, a large proportion of them does not survive the first winter in English gardens. The plants are gathered as soon as they have well made their growth; they are sent over in large packages, and being more or less moist they ferment, so that the foliage is blackened, and they become excited by the warmth to positively start into growth by the time they arrive here. Most of these Christmas Roses are more or less set with buds, and the footstalks of them are blanched and drawn out like those of Seakale. This stimulation just when the crowns should be at rest is in itself productive of harm, and when the plants are exposed in the open ground to the vicissitudes of our winter, they are sure, more or less, to suffer. Even if they do not die, they become so crippled as to require several years to bring them into a flowering condition. Having been in the habit of purchasing imported Christmas Roses, and finding the growth of those that survived so unsatisfactory, I afforded them some shelter through the winter, and in this way I have done well with them. As soon as they arrived I trimmed off all the old foliage, and with a sharp knife cut away all bruised portions of the roots, which are mostly reduced in length, owing to the rough manner in which the plants seem to be lifted. They were then laid in, in light soil in a cool house where they remained till the following April. Some of them were put singly into small pots. It was instructive to note how differently these plants behaved from those planted in the open ground; whilst these latter remained quite inert through the winter, showing no signs of life till spring, those laid in under cover threw up flower-buds and began to form new growths just like established plants. At the close of the winter they were full of plump reddish-looking leaf-buds, showing no signs of the ordeal through which they had passed when torn from their native wilds. Another thing I noticed particularly is, that numerous growths formed on the old black rhizomes where apparently no growths had been made for some time. I fancy that the little extra warmth which they enjoyed caused this, for having no frame room to spare, I was obliged to lay them in along the back wall of a house used for late Chrysanthemums, and where fires were of course made in severe weather. Even if none of the plants died when put into the open ground, it is well worth while to give them protection, as this causes a multiplication of growths and preserves the vitality of the crowns and roots, thus enabling them to make a much stronger growth when put eventually into the open ground. J. C. B.

New Zealand Veronicas.—All the species of New Zealand Veronicas may be said to be hardy in some part or other of this country. In favoured districts, such as the west coast of Scotland, the tenderest of the species flourish luxuriantly, and reproduce themselves from self-sown seed. Here, in Edinburgh, however, such is not the case.

Having for several years back experimented with many different species, with the object of testing their hardness, the following kinds have been found to be thoroughly hardy in all exposures, viz. —

- | | |
|----------------|----------------|
| Salicornioides | Glauco-cerulea |
| Cupressoides | Anomala |
| Lycopodioides | Colensis |
| Pinguifolia | Amplexicaulis |
| Canosula | Lævis |

The following species are very nearly hardy : still, in very severe seasons, in fully exposed positions, they are more or less injured, but they always break away again, viz : —

- | | |
|-------------|------------|
| Traversi | Catacraea |
| Vernicosa | Hulkeana |
| Eparidea | Paviflora |
| Pinchioides | Chathamica |
| Lyalli | |

Those which in severe seasons only are killed outright, and which may be termed half-hardy, are : speciosa, Andersoni, salicifolia, macrocarpa, and diosmaefolia. These are the results obtained so far ; a few other species are still on trial. It will be evident from the above that, with a less rigorous test than that applied here, the majority of the species will succeed admirably in most gardens, some slight shelter being given to the more tender kinds. There are few shrubs more worthy of extended cultivation than the New Zealand Veronicas. They are all evergreen, and many have handsome flowers, which are more or less freely produced, independent of which they form naturally trim, shapely bushes, varying in height from a few inches to several feet. Not a few are interesting on account of certain resemblances which they bear to totally different genera, as indicated by their specific names, mimicking, as it were, plants far removed from the family to which they belong so completely as to deceive not only the unwary, but even the most acute observers as to their identity.—ROBERT LINDSAY, *Royal Botanic Garden, Edinburgh.*

TREES AND SHRUBS.

W. GOLDRING.

THE AMERICAN PITCH PINE.

(PINUS RIGIDA)

THIS is one of the common Pines of the Eastern United States, growing abundantly in that tract of country lying between the Atlantic coast and the Alleghany Mountains. It extends over a wide region northwards and southwards, being found as far north as the Penobscot River, in Maine, to the mountains of Carolina. Its growth is influenced in a remarkable way according to the latitude in which it grows. In the north

Terminal bud of *P. rigida*.

it is but a low tree, rarely more than 15 feet high but in the south it is a large tree 100 feet high or more. To the Americans it is a useful tree, and at one time the Pitch Pine forests

yielded vast quantities of resinous products, the wood being highly charged with resin. Its timber, too, is good, though very knotty, on account of the peculiar branching habit of the tree. But we are not concerned about the timber value of the tree, for it was found out a hundred years ago that our native Scotch Pine was superior to any American Pine as regards the timber, and better suited for our climate. But the Pitch Pine is worth consideration for ornamental planting, and I am convinced that its value in this respect has been overlooked. It has never been a "stock" plant in nurseries, and it is in only rich arboreta that one can meet with it. Any lover of trees would at once single out a Pitch Pine in a collection by its singular habit. The absence of that stiff, formal growth that characterises most other Pines is the chief value of *P. rigida* for artistic planting, and, added to this, it is a

Full-sized cone, leaves, cone scale and seed of *P. rigida*.

rapid and free-growing tree even in the poorest soils and the bleakest situations.

It is, in short, one of those trees to plant in spots where even the hardy Highland Pine will not flourish. Many will agree with me in regarding it as a most picturesque tree, whether they see it 10 feet or 30 feet high. Every tree I have seen always possesses that free informal style of growth, with the branches protruding in no regular way, but generally opposed to each other in direction. The illustration on page 132 shows well what I mean. In this tree some of the branches assume a pendulous growth ; others are horizontal ; while the outline of the tree reminds one more of that of an Elm than a spiral Conifer. The colour of the tree is not very different from that of other Pines, the foliage being of a light green, not glaucous, as in the Scotch Pine ; therefore, when the two Pines are associated with each

other in groups, they give variety of tone. There is a good deal of difference between the various forms of this Pine. Usually the leaves are short and stiff, but sometimes they are long and twisted, and as bright green as those of *Pinus insignis*. The leaves are always produced in

Cluster of cones of *P. rigida*.

three from the sheath, and clustered in a brush-like way at the ends of the shoots. The bark of an old Pitch Pine is always very rough and dark, and from this character alone one may single it out from among others.

The cone of the Pitch Pine is well represented by the accompanying illustration, which shows a full sized cone, but generally they are smaller, especially on trees in dry soils. Each scale of the cone is provided with a sharp-hooked spine, a character by which a Pitch Pine cone may be always known. The cones are produced singly in pairs and threes, but generally in clusters, and these hang on the trees for many years, as in the case of many other Pines. Young trees, when only a few feet high, cone freely and bear perfect seeds. The buds terminating the branches show the resinous nature of the tree as they are always covered more or less with resin.

Enough has been said to show that the American Pitch Pine has its use in ornamental planting in this country, and though it is not a tree to be recommended for planting for the sake of its timber, it could be put to a good purpose as a shelter tree, especially near the seacoast, for it possesses the great advantage of not being injured by salt water. It has been the means of clothing many barren, sandy wastes in the United States, being the best tree that could be found for the purpose. It is recommended to transplant Pitch Pine trees when very young, as they strike root deeply, and are always difficult to transplant successfully when old. This Pine was introduced into England about 130 years ago by one of the Dukes of Bedford, and fine trees of it exist at Woburn, Syon, Pain's Hill, Dropmore, and other places.

Bambusa Castelloni.—This beautiful Japanese Bamboo, known in its native country under the name of Kin-Mei, has recently been introduced into French gardens and has been named as above in compliment to a French nobleman, the Comte de Castelloni, well known for his love of these graceful plants, and who is now engaged on a monograph concerning them, which when published should be of great interest to all growers of Bamboos. *B. Castelloni* is described and illustrated by a well-executed woodcut in a recent number of the *Paris Revue Horticole* by Mons. E. A. Carrière, one of the editors of that publication, and is said to be perfectly hardy. It is one of the curious square-stemmed varieties, and is said to be quite the most distinct and beautiful hardy Bamboo that has yet been introduced to European gardens from Japan. It is of exceedingly tall and vigorous habit

of growth, its stems when they attain their complete development attaining to the splendid height of from 32 feet to 39 feet. It is also remarkable for the beautifully even variegation of its square stems, two sides of which are deep shining green, the other two bright gold colour. The leaves also are prettily veined with yellow. The variegation seems to be unusually even and constant, and to be altogether unaffected by exposure to the sun, which is so often apt to burn and cause to wither the variegated portions of plants when exposed thereto. It is to be hoped that this beautiful Bamboo will soon find its way into English gardens.—W. E. GUMBLETON.

Muhlenbeckia complexa.—This elegant little trailing shrub, from New Zealand, has been sadly injured by the spell of cold, though the plants are probably not killed outright. Those planted among rocks in the rock garden, where the roots are in well-drained soil, are safe, but those on the flat have the branches killed. It is such a pretty trailer that we can ill afford to lose it. Perhaps some readers could tell us how *M. varians* has behaved during the present winter. It appears to be less hardy than *M. complexa*.—W. G.

The Japan Hemlock Spruce.—This Conifer is the Japanese representative of the Canadian Hemlock Spruce, and it is difficult to say which is the most beautiful. Both are extremely elegant in growth, never attaining a great height, but always spreading like a huge bush. They resemble each other very much in foliage, but the Japanese Hemlock is lighter in colour on account of the leaves being glaucous beneath. It is a quick grower in good light soils, and its extreme hardiness adds greatly to its value. As a lawn tree it can only be equalled in gracefulness by its Canadian relative, and, like it, does not form a prim symmetrical pyramid, for it generally possesses a multitude of leaders. To give full effect to its beauty, it should be planted in proximity to a spiral-headed tree, none better than *Abies Albertiana*, which being similar harmonises admirably with it. *Abies Tsuga* (the name of the Japan Hemlock) inhabits the mountain forests of Japan at great elevations, and was introduced about thirty years ago by Dr. Siebold, who named the tree *A. Tsuga*, but subsequently Carrière named it *Tsuga Sieboldi*, under which name it goes in some nurseries and gardens. There is a variety of it called *nana*, a pigmy, never growing more than 4 feet or 5 feet high, whereas the type grows from 25 feet to 30 feet high. Some admirable specimens of the Japan Hemlock may be seen in the Kew arboretum.

The Box-leaved Holly (*Ilex crenata*).—If this little Evergreen was better known it would become one of the most popular shrubs in gardens, large or small, but particularly in those where space is limited. It combines the neatness of a Box without its stiffness, for, though slow in growth and rarely reaching more than 4 feet high, its dense foliage is arranged in pleasing masses. The leaves are very small—not more than an inch long, by a quarter wide—and is therefore so much unlike an ordinary Holly, that one would hardly suspect that there was any affinity between this and other Hollies. There are a few varieties of it; one, called *aureo-variegata*, has the leaves mottled with a bright golden yellow, which, with the green, makes an extremely bright little shrub, especially in winter. Another variegated form has silvery markings. A third variety, named *longifolia*, has longer and narrower leaves than the type; while a fourth variety, named *latifolia*, is distinct from the rest in having leaves almost twice as broad as those of the typical form; hence, has quite a different appearance, and much more like a Box than the other. Every form of this Holly is worth growing, and for making dwarf, compact masses of Evergreens there is nothing to equal them. This Holly is also known under the name of *I. Fortunei*, but in most nursery catalogues the two names are coupled. It is a native of Japan, and is perfectly hardy; the recent severe weather had no effect upon its foliage.

It thrives in most soils, light as well as heavy, the best suited to it being a sandy loam. It makes a capital plant for planting on bold ledges in the rock garden, and for winter beds it is one of the very best shrubs.

IVIES AND THEIR USES.

The common Ivy when growing in an exposed position will often acquire a rich bronzy hue during winter, but in this respect individual plants vary a good deal, the smaller-leaved forms being, as a rule, the richest in colour. The most marked in this respect, and one that from its neat, prettily lobed leaves is well suited for use in the arrangement of button-hole bouquets, sprays, and similar purposes, for which these bronzed Ivies are now so much employed, is the variety named *atropurpurea*, whose distinctive character is far more marked in winter than in summer. It is a matter of surprise that so little attention is paid to the many and beautiful varieties of Ivy now in our gardens, only one or two of the strong growing kinds being as a rule planted, while a large and varied selection might be readily made. Some of them are most beautifully variegated, while the green-leaved kinds show a very great diversity, not only in the shape, but also in the size of the leaves, varying as they do from the huge foliage of *Ragneriana*, *canariensis*, and *amurensis* to the miniature leafage in *caenwoodiana* or *minima*. Besides this, the variety with orange-coloured fruit (*aurantiaca*) should be a welcome addition to berry-bearing shrubs, *i.e.*, if it will fruit freely in this country. As evergreen shrubs, too, the Tree Ivies are very distinct, and withal first-rate town plants. The peculiarly clustered Ivy (*H. conglomerata*), of a low spreading style of growth, is well suited for rockwork. Not the least desirable of the many good qualities possessed by the Ivy is its thorough hardiness.

ALPHA.

Stauntonia latifolia.—This beautiful Indian climbing shrub is perfectly hardy as a wall plant at Sedgwick Park, in Sussex, where it clothes a large part of the stable walls in a luxuriant mass of deep green foliage. The leaflets are broad and of a leathery texture, and remain on the plant for years. In summer it bears a profusion of flowers, which are green and dull purple, and deliciously fragrant, like Violets. For clothing the walls of a house it is a valuable plant. It succeeds best on an east or west wall, full exposure to the south not being suitable for it. It is a native of Nepal.

The Golden Scotch Fir.—“W.” (p. 105) seems to question my remarks very much about this Golden Scotch Fir; what I asserted I still adhere to, and which can be proved by facts, for everyone of whom I have inquired writes me that it is of slower growth than the green Scotch Fir, and is less vigorous. One can understand that “W.’s” chance seedling in a mixed wood would be drawn up with the rest, or it would soon cease to exist. It would naturally keep pace with its neighbours as regards height, but at the same time would perhaps be a wretched tree. Again, being a seedling never transplanted is very different from the Golden Scotch Firs from nurseries, which are grafted plants, so that it is not a case for comparison. It would be interesting to know the present height of the Churchill Scotch Fir, which “W.” presumes “is now standing and must be considerably over 30 feet high.” Perhaps it would be discovered that the Golden Fir had been crowded out by the survival of the fittest, for we all know that golden and variegated plants possess less vitality than green-leaved plants.—W. G.

The Japanese Privet is a valuable shrub for winter, being perfectly hardy, of neat spreading growth, very dwarf, and of a bright lively green colour. Its leaves are broader than those of other Privets, excepting, perhaps, *Ligustrum coriaceum* and *lucidum*, and they are quite smooth and glossy; 3 feet to 5 feet is its usual height, but by pruning it may be kept at 18 inches high, and yet not look formal. After midsummer it bears great spreading clusters of tiny white flowers. A most beautiful

lawn group could be made of the Eastern Privets alone, as they possess such a diversity of habit. For instance, by placing *L. sinense* at the tallest point in the group, one could carry an easy line down to the turf by planting *L. lucidum*, *ovalifolium*, and *japonicum*, while the dwarfest plant would be the singular little *L. coriaceum*, which makes dense tufts of the deepest green foliage. These would make a rich evergreen group, and it could be enlivened by a plant or two of the golden *L. ovalifolium* and other variegated forms. The Japanese Privet (*L. japonicum*) is also known under other names, *L. latifolium* and *Sieboldi* and *spicatum* being the chief synonyms.

Buddleia globosa.—Nowhere, perhaps, does this pretty and distinct-flowering shrub flourish half so well as along the western coast of our island. To see it, as we not unfrequently do, in some of the maritime gardens of Carnarvonshire, when fully a score of feet in height, half as much in spread of branch, and literally covered with its bright orange, honeycombed flowers, is a floral sight that it would be difficult to match. One plant in particular of this *Buddleia* that I could not help noticing the other day measured exactly 15 feet in height, with a well-furnished head of 4 yards in diameter. It was growing in good fine loam, by the side of a large Cypress tree, this, together with an entire circuit of other trees, offering the slight shelter that is so needful for bringing out to perfection the beauties of this Chilean plant. As a wall plant, too, the *Buddleia* is of particular value; indeed, we have always been impressed with the appearance of it when used as such, the globular heads of yellow flowers showing themselves to perfection against the dark-coloured stones, and in conjunction with the long dark green foliage with its distinct silvery tomentum underneath. There is another pretty species, *B. Lindleyana*, but as it cannot survive through even an ordinary English winter, although in warm maritime districts we have seen it doing well out of doors, it is rarely seen. The flowers are purplish red, and produced in terminal racemose spikes. *B. crispata* is another desirable and pretty member of the same family, hailing from the Himalayas, having conspicuously woolly leaves and lilac-brown fragrant flowers. We have propagated the *Buddleias* very successfully from well-ripened cuttings, inserted in sharp, sandy soil, during August and September. When fairly rooted the cuttings grow very rapidly, as much as 3 feet in length being added in one season to those planted in a northern exposure in our nursery grounds. Occasionally the unripened wood gets cut by frost, but this is no loss, as the *Buddleia* is improved by pruning and bears it well.—W.

The White Beam Tree (*Pyrus Aria*).—Most persons will readily admit that on the whole our woods in summer present too monotonous a repetition of varying shades of green, for few indeed are the trees or shrubs whose foliage can be considered as perfectly distinct from the general mass. One or two, such as the plant in question and the white Poplar, are, however, exceptions to this general rule, their foliage affording a very unusual and decided tint of an almost pure white, particularly on the under sides, and which renders them of much value for indiscriminate mixing with our general forest trees along the margins of woods and plantations. For park purposes the White Beam is of great value, and when planted in conspicuous positions on the woodland margins produces an effect that, in my opinion, at least, is quite unapproachable by any other hardy tree or shrub. But not only as a distinct foliaged tree is the White Beam of value, for as a fruit-bearer of the most desirable kind it has certainly few rivals, the big red checked berries being abundantly produced, and imparting to the tree when fully ripe a most pleasing effect, as well as contrasting strangely with the downy white foliage. These berries are by no means unpalatable. Then, again, another point in favour of this tree is that it is very readily raised from seed, for if the berries are collected when fully ripe, placed for a year in sand, and sown in fine sweet loam, the young plants come away rapidly and in

numbers, and in about three years afterwards, if their nursery management has been of the right kind, they are fit for planting out permanently. To see this tree in a shrub state, springing from some of the soilless chinks of the limestone rocks on the Orme's Head, and exposed to the full glare of the noonday sun, is apt to arouse one's suspicions as to how it exists or ekes out the bare necessities of life, for certainly the conditions are anything but what one would consider as favourable for plant growth. Two other rare plants are its companions, viz. *Cotoneaster vulgaris* and that sweet little *Helleboric*, *Epipactis ovalis*.—A. D. W.

The Butcher's Broom under trees.—Mr. Muir's praise of this native Evergreen (p. 106) is not extravagant, and one can picture to themselves the beauty of a dense growth of such a rich Evergreen under the shade of trees, but Mr. Muir does not state under what kind of trees the Butcher's Broom grows so well. Are they deciduous or evergreen, Oaks, Beeches, or what? This is most important to know, as it makes all the difference. It is not uncommon to find a dense undergrowth of Hollies in an Oak wood, but what Evergreen flourishes under Beeches? The only place I have seen the Butcher's Broom growing well under Beeches is in a garden at the foot of Box Hill, in Surrey, on the chalk, but this is a natural growth, and it is doubtful if one could successfully introduce even the Butcher's Broom under Beeches in localities where it is not indigenous. Mr. Muir's assertion that "there are several plants that grow under the shade and drip of trees" is somewhat vague, as my experience is that there are very few Evergreens that thrive under dense-headed trees, particularly Beeches. Perhaps Mr. Muir would kindly give us his list. He is quite right about the Butcher's Broom being a good shade plant, but his experience of it is different from mine when he asserts that it grows rapidly and spreads freely. I should call it a slow grower, and not one of the best plants to establish. It is not only under trees that the Butcher's Broom is a valuable shrub, but as a mass on an open lawn there are not many shrubs to equal it for winter effect, the green being so dark. It makes rather a formal-looking mass, by making it rise out of a growth of Ivy, or by planting near it a group of its relative, *R. Hypoglossum*, the stiffness is relieved. If any one, by the way, thinks of planting the Butcher's Broom, he should see that he gets the right plant, otherwise he will get the dwarf-trailing *R. Hypoglossum*, or double-leaved Butcher's Broom, as this plant was sent to me from a large northern nursery where I was assured it has also been grown and sold for Butcher's Broom, but it is very different and not half so valuable, besides being less hardy.

SHORT NOTES.—TREES AND SHRUBS.

The climbing Hydrangea.—This climbing Japanese shrub introduced a few years ago under the name of *Schizophragma hydrangeoides* has been renamed *Hydrangea volubilis*, as it is found to be strictly a *Hydrangea*, and the specific name *volubilis* is expressive of its climbing growth.

Abies bracteata has been badly injured by frosts this season at Kew. All the plants in the arboretum have their last year's shoots browned, if not killed. It is one of the Californian Silver Firs that are liable to injury from the wet and cold of our winters if planted far inland, but on account of its handsome and remarkable appearance, it is a valuable ornamental Conifer in mild localities.

Euonymus variegatus.—The white variegated *Euonymus* has been particularly bright all the winter. It is indeed the brightest of the family, and the silvery variegation in winter is even clearer than in summer. I have tried to grow it in the form of a bush in the open, and have trained it to walls in different aspects, but nowhere is it so bright as on a low wall with a north aspect. It does not make a handsome bush, owing to its growth being too straggling. This variety must not be confounded with the large-leaved variety with golden and white variegation. —SOMMERSET.

Carpenteria californica (p. 100). I should say that the hardiness of this fine shrub is beyond all doubt. This is the fifth winter in which I have had plants in the open ground, and I have never seen a leaf injured by the frost. My plants are not against a wall, but are in sheltered spots. Last autumn I planted out some young plants in more exposed places, and as yet they seem to be quite uninjured. I should like to know if it has seeded anywhere in England. Last year I had plenty of seed-pods, but not a single perfect

seed was formed.—HENRY N. ELLACOMBE, *Bilboa Vineyard, Gloucestershire.*

I fear I must not accept the credit given me in THE GARDEN (p. 100) for being the first to bloom this beautiful shrub, as I believe both Canon Ellacombe, in Gloucestershire, and Mr. Ewbank, in the Isle of Wight, had it in flower a year sooner. G. JERRELL, *Monstead, Godalming.*

MAGNOLIA GRANDIFLORA AND HALLEANA.

LET me recommend to "W." not only *M. Halleana* (which is a double form of *stellata*, so common in Japanese drawings, and of which there used to be a small plant at Coombe Wood), but *M. parviflora*. The *M. Halleana* was named after a Dr. Hall, who introduced it from Japan into America. I have grown it for years, and a more lovely plant does not exist for spring gardens. Belvoir should be full of it. I am going to surround my little plant (it never grows big) with *Pyrens Maulei*. In spring it is covered with white flowers resembling the double white Poet's *Narcissus*. *M. parviflora* I have introduced from America, but it is originally from Japan, and bears—flowering when quite a tiny plant—a deliciously scented, cream-coloured flower, with a dark centre about 4 inches across. One bloom scented the garden here last June. It is deciduous, and resembles another species, *M. hypoleuca*. *M. tripetala* I also have. It will flower when young, and grows into a big tree. It is American, and deciduous and perfectly hardy and manageable. The flower is about 10 inches across, creamy, like the *grandiflora*, only more spread out. *M. macrophylla* I also have, and it is American, and allied to *tripetala*, but not so easy to grow. The flowers are 1 foot across, and rather more double than *grandiflora*. It is, again, deciduous and summer-blooming, as are *hypoleuca*, *parviflora*, *tripetala*, and *glauca*. *M. Thompsoni* I have lost, having no peat or swamp for it. This is a lovely plant in the right place, and deliciously scented. It was raised at Fulham in 1804 from *glauca*, and I expect is a hybrid. *M. hypoleuca* I have. This is a superb summer-blooming species from the north island of Japan, and therefore quite hardy. Mr. Maries told me he saw forests of it intertwined with *Schizophragma hydrangeoides*. It is deciduous, and has creamy flowers.

Of the early-flowered kinds I have the rare *M. Thurberi*, but not bloomed it yet. *Yulan* and *purpurea* are too well known to want a description, but everyone who can should see the great *Yulan* at Waterer's nursery. It is the whitest variety, and fills the air with its silver cups, and litters the ground with its white wings. People sometimes will not plant these glorious trees because they make such a litter. *Magnolia Lenne* is perhaps the noblest of this class, while *Soulangeana nigra* is the most remarkable and distinct. *Magnolia Campbelli*, the finest of all, has not yet flowered in England, though it has in Ireland. It has proved perfectly hardy. There are still other species to be introduced from Japan, notably a flower with its outer petals deep purple, and its inner ones white. If anyone gets seed of the spring-flowering *Magnolias* I should like to have some. All these *Magnolias* are, as yet, quite small plants.

FRANK MILLS.
Shirchampton, Bristol.

The Sweet Fern shrub (*Comptonia asplenifolia*)—This pretty fragrant bush is only neglected because not known. It combines elegance of growth and sweet perfume in a way that no other shrub does. It grows about a yard high, and grows to perfection even in the poorest soils; in fact, it is a native of the dry hill-sides throughout the Eastern United States, from Georgia to as far south as Carolina. It is a deciduous shrub, the foliage being cut so as to resemble a Fern frond. When young they are of a bright cheerful green but as they get older they get duller. The bark of the shoots, too, changes colour, and when old are of a rich reddish brown. The branches hang gracefully on all sides, and the whole plant gives out a pleasant spicy perfume, especially when the leaves are crushed. It is a plant that

one should have a mass of near the house, in association with other sweet-smelling plants like Lavender, Rosemary, Sweet Brier, Sweet Gale, and the like.—W. G.

KITCHEN GARDEN.

W. WILDSMITH.

ROTATION OF CROPS.

LITTLE scientific knowledge is necessary to a full belief in the importance of repeated changes of ground for kitchen garden crops, but to fully carry out a regular systematic rotation is more difficult than many imagine. For at least eighteen years I have striven to keep to the plan, and for just as many years I have failed, but, in justice to myself, think it right to add that the reason of failure has been that greater supplies have been demanded than the limited extent of ground warranted; consequently, cropping the same ground twice and often thrice in a year has to be done, and thus all our correct notions as to rotation have to be set down as nearly a blank; not quite, as, for instance, on no consideration do we plant Cabbage on a plot where there has been Cabbage or its kindred, the Broccoli, Kales, and Cauliflowers, immediately preceding it; and the same in respect to roots, as, for instance, Carrots never follow Parsnips, and *vice versa*. Onions, Leeks, Celery, and Lettuce are more accommodating, and if the ground is well tilled, these may be kept to the same ground for several successive years without any apparent deterioration. But, for all that, I would always advise their being changed when practicable. In places where there is plenty of ground to meet required supplies, a regular system of rotation cropping is an easy matter, and should be scrupulously adhered to, as being not only the proper method, but economical also, inasmuch as one manuring will on an average serve for two main crops, as, for instance, a good manurial dressing applied for Onions would do well if deeply dug for Carrots, Parsnips, or Beet: or, again, the dressing required for Celery makes the best of all preparation for the main crop of Potatoes the year following. The foregoing notes are the result of a reference to my kitchen garden notes for February of last year, in which there is a note as to the difficulty of finding a more suitable plot of ground for Onions than the one so occupied the year previous, and which, as it happened, had not, contrary to our usual practice, been cropped with Cabbage; having been trenched and manured, it was at once available, and was so cropped, with good results, but not quite up to the usual standard, though, according to the pains taken in the preparation of the ground, the crop ought to have been better, a circumstance that scores a black mark against successive cropping with the same kind of vegetables.

New kinds of Potatoes.—I have raised some really first-class kinds of Potatoes and have good reason to be gratified with my success in that direction. When a writer declares, as "E. T. G." does (p. 57), that there is no Potato which can at all compare with the Regent, what good is it to waste pen and ink in trying to enlighten him? However, for the benefit of others I may say that in my opinion *Harvester*, *The Dean*, *Prime Minister*, *Fidler's Prolific*, *Prizetaker*, *Reading Russet*, *Standwell*, *Early Regent*, *Sutton's Seedling*, *Abundance*, and *Edgecot Seedling* are a few, and but a few, amongst many that are really first-class cooking Potatoes, and generally much better and safer croppers than the Regent.—A. D.

White Elephant Potato.—For some time after *White Elephant* came out, owing to unfavourable reports from people who had grown it, I fought shy of it; but now, after two years' trial on a small scale, I have reason to regard it as a good variety, and intend to grow more of it in future. Our main crop Potatoes for some seasons past have been *Schoolmaster* and *Magnum Bonum*; of these two sorts *Schoolmaster* is decidedly the best in our stiff soil

(near London), and as a cropper it is almost equal to Magnum Bonum. Reading Russet and Vicar of Laleham are sorts well worth a trial. Milsummer Kidney is a handsome early Potato of good quality.—E. B. L.

POTATO CULTURE.

SEED POTATOES.—Hitherto, except among early kinds, there has not been much growth, but since a change in the weather has come Potatoes stored in bulk are pushing rapidly. The best way to manage all seed Potatoes is to place them in shallow trays, or baskets, crown upwards, and, as far as is possible, bring them into the light. Potatoes laid in heaps will ferment, as it is in the nature of all vegetable substances when in bulk to generate heat if left long undisturbed, but if the seed Potatoes, where it is not possible to spread them out in single layers, were turned over weekly with a barn shovel, this tendency to grow out will be materially checked, and when at last growth does come the shoots would be strong and need not be rubbed off.

TABLE POTATOES.—Considering the number of varieties in cultivation, the number of kinds that are good on the table is very limited. No doubt a good deal of this dissatisfaction with some of the popular exhibition kinds arises from cultural conditions. The high-bred varieties want peculiar treatment. They, or at least some of them, are the outcome of special conditions and circumstances, and when these are absent, they are close, waxy and useless. Except on the best Potato lands, I am doubtful if any grower could honestly recommend half a dozen good profitable table Potatoes that are always reliable. The Ashleafs are always good in the early part of the season—the old Ashleaf for first crop succeeded by Myatt's prolific. Earliest of All, a variety sent out by Messrs. Carter, I believe, is a good early kind and produces an excellent crop. After the first and second earlies I cannot find anything to beat the Regents and Schoolmaster, which seems to have some of the good qualities of the Regent, and is at the same time more vigorous and a better cropper, and will keep in usable condition longer. At the present time (January 20) I do not know any kind better for table than Schoolmaster, and it will be in condition for some time longer, and, taking into consideration the reports which I have heard from various districts, that for general use from August till March there is no Potato which has so many good points on all kinds of soil as the Schoolmaster. As regards a very late Potato, I have tried a good many kinds in my anxiety to get hold of a good one. The Magnum Bonum crops well everywhere, but its quality is only good on suitable land. It is a profitable Potato to grow, but I have never seen it so good as Schoolmaster on the table. Reading Hero I have had very good, and I have also had it very inferior. Soil and season affect its condition much. Perhaps, on the whole, there is no better late Potato under all circumstances than the Scotch Champion, but in many districts where it was formerly grown largely it has been discarded, because it did not succeed so well as formerly, and it is evidently on the wane. Frequent change of seed direct from Scotland should be carried out by all who wish to continue its culture.

MANURING POTATOES.—Here, again, the condition of the soil should be taken into consideration, but a well-blended compost made up of such ingredients as wood ashes, charred refuse, old decayed turf, and well decomposed yard manure placed in the drills with the sets will have a good effect upon the crop. I may say in passing, it is worse than useless to plant any but early and second early kinds upon heavy land, though the Schoolmaster succeeds better than any other main crop Potato I am acquainted with in such land. In a general way it pays to use a little artificial manure for Potatoes, either placed in the drills at the rate of 4 cwt. or 5 cwt. per acre, or used as a top-dressing after the Potatoes are up, just before they are moulded up. The manures most com-

monly used in this district are superphosphate, and heavy dressings are sometimes used. For poor land a dressing of guano and nitrate of soda at the rate of 2½ cwt. of each per acre has produced beneficial results. It is best applied as a top-dressing as soon as the plants are up, when it can be hoed in. I would rather plant medium-sized whole sets than cut large Potatoes, though I freely admit that the central eye from a large Potato does produce a strong stem and a good crop of even-sized tubers, but there is a great waste in planting a large Potato for its one strong eye in the crown. Small or inferior sets should not be planted at all, as their continued use has a deteriorating effect upon the stock.

PREPARATION OF THE LAND.—The more the soil is opened up at this season the better condition it will be in, always supposing that frozen soil is not turned in, and that the land should not be worked or trampled when covered with snow or saturated with rain. The planting should take place when the surface is dry and has been mellowed by exposure to the atmosphere. The distance left between the rows, especially for the vigorous growing kinds, is often too small for the best results. I do not think any main crop Potato should have less than 3 feet between the rows, and in the case of the vigorous kinds 4 feet will be better, and it is an advantage to have the rows run north and south, so that the sun may shine on both sides of the ridge with equal power.

E. HUBBAY.

EARLY AND MAIN-CROP PEAS.

WHAT is the earliest Pea? Among the notes I made last summer, the very earliest was one named somewhat appropriately Earliest of All, and it is evidently a precocious selection from the Sangster's No. 1 type. But Sutton's Emerald Gem ran it very closely indeed, and by some it is considered the earlier of the two. Almost equal in point of time was Selected Extra Early, also one of the Sangster's No. 1 type. But anyone who can lay hold of William the Second (not William the First) will have a first class early Pea, bearing freely fine large green pods, and not more than 3 feet in height. I do not know who sent it out, but gardeners should make a note of it. Next in order of time came American Wonder and Maclean's Early Gem—Peas that are of very dwarf growth, and very useful for small gardens, and these are only a very few days behind the others.

Surpass William the First is one of Mr. H. Eckford's Peas, taller in growth and three days earlier than William the First, a rare cropper, and not quite so curved in the pod. A variety called Special Early was one day later than the preceding, and not so good in the pod. One named Extra Early is of tall growth, and may be termed an early *Ne Plus Ultra*, large, handsome pods, and a great cropper—an early exhibition variety that should be noted by those who grow Peas for early shows in July. Day's Early Sunrise is often recommended as a first early, but it is a mistake to say this much of it; it is really a second early variety only, but very useful, as it produces good pods, is a great cropper, and is not more than 3 feet in height. I was much pleased with a dwarf variety named Chelsea Gem, 18 inches to 2 feet, white pods, a good cropper, the pods slightly curved; also a very useful variety for early exhibitions. Dickson's Favourite should be noted as a good market gardener's Pea, because it is such a heavy cropper; but it should have sticks to do it justice. Essex Rival is also a heavy cropper, a good early Pea for amateurs' small gardens; and Gladiator must be mentioned as a very promising second early variety, one that should be grown for early July exhibitions, 2½ feet to 3 feet in height, long pointed, green pods, good, sturdy habit of growth, and a great cropper. John Bull is also a vigorous grower, with a good branching habit, 3 feet, and bears large white pods. President Garfield is a fine robust-growing variety, producing large white pods, a little taller in growth than John Bull, and an excellent cropper. It is a variety well worth attention, and without in any way derogating from its merits, may be taken as representing a very fine selection from Veitch's Perfection. Dr. Hogg has fine white curved pods; it grows

from 3 feet to 4 feet, and as it was fit to gather on June 30 last season, it is a valuable variety for early exhibitions. Like some others of Mr. Laxton's raising, it is of a mixed character, some of the pods being white and some green. That Culverwell's Giant Marrow is a fine-looking Pea, there can be no doubt; it grows to a height of from 4½ feet to 5 feet, and produces large, white, pointed pods, but they do not sometimes fill out so well as could be desired. Sturdy is a capital Pea for small gardens; it grows to a height of 2½ feet; the pods are not large, but they are very freely produced, and it may be set down as an abundant bearer. Unique is a dwarf and somewhat early variety, not getting beyond 12 inches to 18 inches in height, and bears medium-sized white pods that fill well. Marvel is a very robust grower, 2½ feet in height, large, long-pointed pods, white; a good exhibition variety. Another good Pea for small gardens is Magnet, 2 feet, bears whitish green pods, that fill well; an excellent cropper and a capital amateur's and cottager's Pea. Huntingdonian and Champion of England are alike; I have no doubt that originally the former was a selection from the latter, and there is no doubt but that Champion of England, when represented by a fine selected stock, is a capital garden and market variety. Fillbasket is a dwarf Pea, 2½ feet to 3 feet, a great cropper, and bears curved white pods, and it may be taken as representing a fine selection from the old Scimitar, so popular thirty years ago. Telephone, round, and Telegraph, wrinkled, are two Peas that, it is said, came out of the same pod, but the former has white, and the latter green pods, and not quite so large; of the two, Telephone has come to be most grown both for garden and exhibition purposes. It is an excellent variety for early shows in July. Sharp's Triumph grows to a height of 2½ feet, and has long white pods slightly curved; it is also a capital exhibition Pea. A new variety named Cowell's Marrow is rather tall—1½ feet—and bears large, long, white pointed pods; it is an excellent cropper, and in all respects a first-class Pea, and especially so as a table variety. Sensation has large pointed pods, a good cropper, and grows to a height of 4½ feet. Proligity is a tall growing Pea, fully 5 feet, bearing large, green pointed pods, and is a fine and good looking variety, and should, I think, be found an excellent main-crop variety for large gardens. Chancellor is dwarf growing, not more than 2½ feet, and bears large white pods. Wordsley Marrow is a very prolific variety, with small green pods very abundantly produced.

I have no hesitation in naming the following varieties as well adapted for garden culture and show purposes, viz., Surpass William the First, Gladiator, President Garfield, Dr. Hogg, Marvel, Telephone, and Cowell's Marrow. And to have fine exhibition pods, let the Peas be sown thinly—at least a foot apart—in deep rich soil, and when five or six trusses of bloom are produced and have set the pods, the tops should be pinched out, so that the whole vigour of the plant can go to the production of large, handsome, well-filled, and well-finished pods. The plants must be supported, and the pods should not be allowed to drop near the ground, where they are in danger of being splashed by the soil thrown up by heavy rains.

I find great differences among judges of Peas. I have met with some who will pass over all the white-podded varieties and give the preference to those with green pods, giving play to prejudice rather than to proper judgment, and acting unjustly in consequence. Some have a *penchant* for particular varieties, and go for them, to the exclusion of all others; and when their ruling is objected to on the ground that the rejected pods are, in some instances, better and more finished, shelter themselves under the assumption that they went for flavour. I think that flavour is often made a hobby of too pronounced a character, especially as I find great difference of opinion prevailing as to what constitutes fine flavour in Peas. Some prefer sweet, soft, melting Peas; others, those that are of a firmer texture and more mealy character. I care not whether the pods are green or white, and if, say, thirty or fifty are shown in a dish, I require that they be large, according to the sort, handsome, even in appearance, well filled,

and with that nice fresh appearance that denotes fitness for table; and, above all, I like to see a bloom upon them, which testifies to good cultivation.

R. D.

EARLY VEGETABLES.

In order to obtain these as early as possible in the open air, three conditions are necessary, viz., a southern aspect, a dry, warm soil, and some temporary shelter. In some gardens there are narrow borders in front of the glasshouses, which are the best possible positions for early Potatoes, French Beans, Horn Carrots, dwarf Peas, &c. It is a very easy matter to make the soil in such borders deep, and to lay the surface at such an inclination as will catch all the rays of the sun. The next best position for early crops is at the foot of a south wall, and the nearer the plants can be placed to the wall the better. A row of dwarf Peas placed parallel with the wall, and about 6 inches or 8 inches from it, will be much earlier than if away from its shelter. Potatoes, Lettuces, Cauliflowers, and French Beans will profit in like manner from contiguity to the wall's friendly surface. A thick hedge is not a bad substitute for a wall, so far as mere shelter goes, but the hedge does not absorb heat from the sun's rays during the day and give it off again at night, and, therefore, to that extent the hedge is inferior to the wall. A Reed or a board fence, blackened with a coat of tar, forms a very good back to an early vegetable border. And if the surface of the border inclines abruptly to the south, the position will be warm and early. A garden provided with a ridge of this character, backed by a hedge or a temporary screen, should not be deficient in early vegetables. Of course the soil must be deep and as good as it is possible to make it, but composts are better than raw manure. Very often during our springs there are periods of cold weather when even all the advantages I have named might be supplemented with some temporary shelter. A covering of netting, such as is commonly used to protect seeds and fruit from the depredations of birds, has a very great protective effect in warding off spring frosts and breaking up cold currents. The thin covering of netting, drawn tightly over a bed of early Lettuces, Cabbages, Cauliflowers, or dwarf Peas, 18 inches or so above the plants, does not seem to shelter them much, but one has only to watch the progress of the plants so sheltered, and compare them with others near which are uncovered, to be convinced of the value of even the thinnest covering from the end of February through the spring. It may be advisable in the case of special crops to introduce a little bottom-heat in the shape of stable manure, placed in the border in sufficient bulk to ferment. A space 6 feet or so square, excavated 2 feet deep, filled with warm stable manure, and covered with 8 inches of free-working mellow soil, will produce a good many Early Horn Carrots, Radishes, &c.; but for such beds either straw covers or oiled calico, tacked on light frames, should be provided. Of course, glass would be better still, but I was thinking only of the early crops which come on in succession to those grown under glass, and in the majority of gardens only a limited amount of glass can be devoted to vegetable forcing, owing to the demand for flowers, &c., which has to be met.

E. HOBDAV.

SHORT NOTES.—KITCHEN.

Chou de Burghley.—"F. R. H. S." has undoubtedly got this Cabbage. If sown under glass in March it brings good heads in October, which last through the winter. Chou de Burghley, unlike other Cabbages, never cracks. If another sowing is made in the first week in May, the produce will be ready for use in February and will last until ordinary Cabbages come in. It is dressed for table exactly in the same way as other green vegetables, but its flavour is superior to that of all Cabbages.—THE RADISH.

Possin Lettuce.—This is catalogued by Messrs. Vitch, of Exeter, but apparently the variety is not much in demand. It is, nevertheless, an excellent sort for standing drought. Three years ago it stood firm in the month of August, when other varieties alongside of it had bolted.—A. H.

KITCHEN GARDEN NOTES.

PARSNIPS.—Sowing these early is a point of the greatest importance, and, given favourable conditions as to soil, the end of January is none too early. Fortunately, Parsnips are very hardy, and severe frost does not harm the small seedlings a bit. Depth of soil rather than undue fertility of it should be aimed at, as it conduces to the descent of the main roots in straight form; whereas in a rich soil, and particularly if it has been recently manured, strong roots form in every direction, and the produce, though possibly of greater bulk, is ill-shaped and cuts greatly to waste in the dressing. A sandy loam is the perfection of soil for Parsnips, and the best fertilisers soot and burnt wood ash. In stiff, heavy soils the roots do wonderfully well when once they have got a fair start, and the first preliminary to that end is to prepare a good seed bed. Such land will not for some time be in a fit condition for sowing, but as soon as it will bear to be trodden upon, draw wide drills to a depth of 4 inches and

The American Pitch Pine (*P. rigida*) in England. (See p. 128.)

18 inches apart, and strew thickly in them a mixture of fine dry soil with leaf-mould and wood ashes added; on this sow the seed thinly, and fill in with the same light soil; press down the soil with the back of the rake and the work is complete. The same distance apart of drills meets the requirements of naturally dry soil, and the soil for the seed drills in that case need not be of an artificial description. The Student is the only variety we grow, being handsome and finer grained in flesh, though not a bit better in quality than the Hollow-crowned and Guernsey varieties.

ONIONS.—Our ground now works nicely, and the first bit of kitchen garden planting has been done to day (Jan. 29). Autumn sown Onions being much too thick, have been thinned out to 4 inches apart, and the thinnings planted at the same distance in rows 15 inches apart. We plant with small dibbers, and only sufficiently deep to ensure the plants being firm in the ground. In

the rows thinned, we found it necessary to draw a little soil to the Onions, and well firm them to keep them upright. A thick dusting over with soot was afterwards applied to the whole plot, with a view to prevent an attack of grub rather than as a fertiliser, of which, however, it is one of the very best. The main crop of spring-sown Onions we like to get in by the middle of February. The ground is now being prepared by levelling it down with a coarse rake and picking off the largest stones; a dressing of burnt wood-ash and soot will then be given, and afterwards the final rake over preparatory to drawing the drills at distances apart of 15 inches. We sow but thinly, and so lessen the labour of thinning out the seedlings. Thin seeding implies the greater need for care in covering in the seed, which we do by hand. Rolling or beating down of the ground is not needed; indeed the practice is injurious unless the soil be exceptionally dry on the surface. The ground selected is the Carrot ground of last year, which as soon as the crop was lifted in November had a good dressing of farmyard manure, and was dug a couple of spits deep, and left rough during the winter, and the frost and snow have made it as friable as the best potting soil, so that with the dressing of soot and ash, as above named, we expect to have an extra fine crop of Onions, without any further labour beyond thinning out and hoeing to keep down weeds.

LETTUCE, RADISH, AND EARLY CARROTS.—These are required in quantity in all gardens, and as small sowings of each at frequent intervals is the best way of continuing the supply, any small plots of ground that are comparatively useless for other vegetables can be made available for them. Our first sowing of Lettuce and Radish has just been made on a narrow fruit-tree border, that as yet the roots do not wholly monopolise; soon as this happens, our veneration for the full rights of the fruit trees to the whole border hinders all further vegetable cropping. Paris White Cos Lettuce, Early French Breakfast Radish and Early Nantes Carrot are the kinds now sown, and the latter is on a narrow border facing west, which is destined for next winter's supply of Parsley, to be sown as soon as the crop of Carrots is exhausted. The sowing we do very thinly in drills 9 inches apart, and thinning out is then unnecessary till it can be done by drawing them for use.

ROOT STORES.—Potatoes are of the first importance. We prefer to winter them in cellars or dark frost-proof sheds; they can then the more conveniently be got at in all weathers. Our stock is getting low; consequently there is ample room to spread out what remains to prevent premature sprouting. Some we find already manifest that tendency, and rubbing off must be done forthwith. The seed tubers have for some time past been laid on shelves in single file, and only the first early varieties show any signs of sprouting, a circumstance that shows the value of laying the sets out in this fashion, as some of the self-same varieties that have been stored in heaps have sprouts a couple of inches in length. Beetroot we have this season stored in Cocoa fibre, and it has kept perfectly, being as fresh and highly flavoured as if just lifted from the ground, and there has been no decay whatever. Carrots were got in dry and built up in heaps without any material between them, and they have also kept better than when we stored them in sand, dry soil, or leaf-mould, all of which seemed to assist decay, probably, I think, because small rootlets formed in the various materials, and consequently growth was excited, which, occurring under the artificial conditions of darkness and a confined atmosphere, tended to decay, a recurrence that the experience of the present season will prevent in the future. Parsnips we always winter in the ground, but as soon as the tops start into renewed growth, we lift and stack them up in a frost-proof shed. This must be done at once, as the recent mild weather has excited growth and

the roots get tough, or what is called stringy, if left in the ground after this. The remainder of the roots of Salsify and Scorzonera are rendered comparatively valueless by the supply of Seakale and Asparagus. Moreover, they, like Parsnips, get tough as soon as renewed growth begins, which, though we had them stored dry like Carrots, is really the case; hence, what remains will be thrown away. A dry store-room is essential to good and long preservation of Onions, and they must never be laid thickly together, or decay is certain. If shelf space for single layers is not at command, they ought to be tied in the old-fashioned way on strings, to hang up in any dry, airy place. We are fortunate in having an excellent store-room for them, and by taking the precaution to have them well harvested—dried—before housing, it is seldom we have to pick out a bad bulb or are troubled with premature growth.

COTTAGER'S KALE.

From the time that has elapsed since this vegetable was first brought under public notice, one might have supposed that it would have been more generally cultivated than it is. When first distributed it received a high character, not only for free growth, great weight of crop from the ground occupied, hardness, enabling it to withstand the severest winters, but, above all, for fine flavour. This high character has been fully borne out, and still we find numbers of gardens in which this, the best Kale in existence, is not grown, and the place in which it should be found occupied by Scotch Kales, which are much inferior to it in flavour, and not superior in their power to withstand severe frost. The first season in which it was distributed I grew it; but at the time of planting I noticed that there was a considerable difference in the plants, some being green in the stems like ordinary Kale, others having more or less of a purplish tinge. I at once concluded that the seed had not been carefully sved; that is, the seed plants had been, when in flower, growing too near some other of the Brassica family in bloom. Subsequent experience proved that in this I was mistaken. In planting, the green plants were put on a separate plot from the purple ones, but were treated in every way in a similar manner. In any plant essentially of a decorative character, novelty of some distinctive kind is a sufficient warrant for its cultivation. Not so with a culinary vegetable, the legitimate use of which is to be eaten. Consequently, I submitted this Kale to the test to which, with me, new vegetables were always subjected, viz. comparison when cooked with the best established variety that admitted of being tested with the new comer. On that occasion, late in the autumn, I had Brussels Sprouts, Walcheren Broccoli, and the purple and green varieties of the Kale cooked separately; also the two forms of the Kale cooked together. The verdict of myself and several friends was, that the green form was very much inferior to the Brussels Sprouts both in flavour and texture, being tough and stringy, and that, when cooked with the purple, completely destroyed the flavour of the latter, as well as gave the whole a disagreeably strong character. This mixture of the purple and green forms has doubtless had the effect of depreciating the value of this vegetable, for the purple, when cooked separately, was as different as could be, being as tender as Spinach, with a flavour more like that of Walcheren Broccoli than the Sprouts, the latter only surpassing it in appearance. From that time I have always grown this Kale as a crop to succeed Brussels Sprouts, giving up the Scotch Kales altogether, except a dwarf variety that is the latest of all in running to flower, and which bridges over the time from the end of the winter greens until the first early Cabbage comes in. From the impression I had first formed respecting the seed plants being improperly managed, I determined to save my own, selecting nothing but purple-stemmed plants; I kept them completely away from any other of the Brassica family, and, when in bloom, carefully covered them with hexagon netting, that effectually excluded bees and flies, yet the seed from these purple plants so treated produced as many green plants as of the colour wanted.

The practice I have followed from that time has been simply in planting to reject all green plants, only

using such as had the unmistakable purple tinge in the stems. To secure a full, heavy crop it is not necessary to sow the seed as early as in the case of Brussels Sprouts, yet it should be in the ground by the middle of April. The land should be well prepared by a good dressing of manure, dug in not too deeply, for this, like all others of the Cabbage tribe, is a surface-rooter; and, although all the family prefer a heavy, strong soil, still it should always be well pulverised, so that the roots can extend in all directions without the obstruction of big, hard, unbroken lumps, that alike offer resistance and afford little nutriment to the tender feeding rootlets. An opinion sometimes exists that in the preparation of ground for culinary vegetables, if a sufficient quantity of manure is dug into the soil within the distance that the roots of the intended crop will extend, this is all that is required. Such is by no means the case. The limited season that most culinary vegetables have in which to arrive at maturity necessitates the whole of their manurial food being evenly dispersed through the soil in which their roots extend; so that, from the day the young plant appears above ground until it is fit for the cook, it may have had all along a continuous supply of the necessary food. This cannot happen unless the manure is evenly dispersed through the soil, which is an impossibility, unless, in digging, the ground is broken sufficiently fine, so as to admit of the equal dispersion of the manure. This, as will be obvious, is of less importance in the case of any plant that requires years to come to maturity. If space can be spared, the plants may be at once put out from the seed-bed when large enough to handle, or they may be pricked out about 9 inches asunder, until some other crop is cleared off to make way for them. A few words respecting this preparatory process may not be out of place. The freest-rooting plants in existence have need of all the roots they make; consequently, in transplanting even so common a vegetable as a Cabbage, it is essential to prescribe as many of the roots free from mutilation as possible; yet how often are these and other plants treated as if their roots were of little or no importance. As regularly as the seasons come round there is the recurring lament over Lettuce prematurely running to seed; Celery and similar things bolting. Can it be wondered at when, in taking up for re-planting they are simply dragged out of the ground like weeds, three-fourths of their roots being ruthlessly torn off? Of the bad results arising from this barbarous work it is difficult to speak too forcibly. The necessity of using a trowel when planting, or of loosening the plants with a fork, so as to retain all the roots possible, may be insisted on, and yet not be always carried out by one's workmen. If anyone is doubtful as to the effect it has upon the crop ultimately, he may be convinced by simply noting the difference there will be all through the after-growth of any given crop, a portion of which is removed with all their roots intact, as compared with another portion torn up weed-fashion.

In preparing a nursery bed for this Kale, and all its congeners, the surface on which the soil is placed should be composed of as hard a material as can be got, so that the roots of the plants cannot penetrate it; and the 6 inches or 8 inches of soil placed thereon, in which they are pricked out, should be thoroughly pulverised before the plants are put in, so that when removed they will come away with nearly all their roots entire. The plants in the nursery bed should never be overcrowded—9 inches each way is a good distance; when they are well cared for, and assisted with water when they require it, good crops can be obtained, even when they are removed to their ultimate destination in the garden later in the season by some weeks than would be of any use attempting with badly prepared plants. This is an advantage, more especially where space is limited. Cottager's Kale, like all other vegetables intended to stand the winter, should not be planted too thickly; the weakening influences of overcrowding show themselves, and render plants unable to resist an amount of cold that they would have withstood without injury, if they had had room sufficient for light and air to give them their wonted strength. If the plants are put out in the quarters where they are to remain as early in the spring as they are large enough to handle, they should be planted 2 feet asunder in the rows, and the rows should be 2 feet 6 inches apart; if

planted later in the season from the nursery bed 2 feet each way will be sufficient. T. B.

RAISING CUCUMBER PLANTS.

The best way of raising plants is certainly in a manure frame or pit. A one-light frame is generally sufficient for the purpose, and care must be taken that the hot manure be perfectly sweet, and the bed of sufficient capacity to ensure a fine growing temperature for a month or six weeks from the time of sowing the seed. For this purpose a mixture of manure and leaves is preferable to manure alone, for they are less likely to heat violently, and consequently they retain the necessary temperature for a longer period. The bed being formed and the frame fixed in its place, it will be necessary to wash the glass perfectly clean, so as to command all the light possible. Then fill the frame to half its depth with sifted leaf mould, old tan, or cinder ashes, and as soon as that has attained the proper temperature, 80° to 85°, it will be fit for use. The seed should be sown in a pot of light soil, say loam and leaf-mould in equal proportions. Plunge the pot in the bed and cover it with flat glass, partly to increase the temperature, but more to protect the seed from the deprivations of mice or other vermin. In three or four days, according to the age, the seed will be up, and then it will be necessary to raise the plants to within a few inches of the glass, and to keep, night and day, a gentle circulation of air. The temperature should not fall much below 70°, and may rise to 80°, with bright light and plenty of air. In raising plants it is always desirable to keep them as short and strong as possible, and this cannot be effected except by a free exposure to light and an equally free exposure to air. When the seed-leaves have attained their full size will be the right time to single the plants out and place them in separate pots. For this purpose some warmed compost and clean warmed pots must be provided, and one or two plants, according to the kind, must be placed in each pot. Drain each pot with a little Moss and some flaky leaf soil, so that it may not be necessary to remove it at the time of planting. After the plants are potted they may be plunged in the frame, watered, and kept close for a day or two, shading them also should the weather be very sunny. So soon, however, as the plants have taken root, increase the quantity of air, and keep a gentle circulation by night as well as by day. When three weeks to a month old the plants will be fit to ridge out, but if the bed should not be ready they may be shifted into larger pots with advantage. Be particular that they do not receive any check, as upon that much of the future success of the plants will depend. C.

MARKET GARDEN NOTES.

EARLY PEAS.—The first sowings of these have been made during the past week, the drier soils being in excellent order for the purpose; whilst some growers still draw their drills with hoe and line 2 feet apart, others use the horse drill, sowing in rows only 18 inches apart, but, of course, much more thinly and evenly. Generally the weight of seed sown per acre—about 2½ bushels—is the same in each case, but with the drill the seeds lie less deep, and, whilst sooner up, are also in greater danger from birds. The chief sorts are Sangster's Improved No. 1, a good stock of an old kind, and William the First, the former for the first gathering. These sowings follow chiefly after autumn Broccoli, early Coleworts, or Turnips, or where winter Spinach has failed.

WINTER SPINACH has been a singular failure this winter, arising from some unknown cause, but apparently from a kind of fungus. The plants, when fairly strong in the autumn, showed evidences of decay in the stems at the base of the leaves, the parts turning brown and quite soft. As a consequence, the plants disappeared rapidly, and many acres were soon left almost without a plant to be seen. Such a misfortune has greatly helped to promote market growers' difficulties, as, on the

whole, Spinach I as usually proved to be a reliable and a profitable crop. Some growers have held that the soil is Spinach-sick; others, that the ground is too full of manure; and others, that the plants suffered from exceptional rains at a critical moment. The mischief was done too late for remedy the same season.

HEARTED CABBAGES—These have suffered so much from frost and snow, that large breadths of what otherwise might have been profitable heads are now half rotten, and smell most unpleasantly. That is but another sample of the uncertainties which hang over market gardening. Sheep are not plentiful in this locality, Middlesex not being an agricultural county, but if a flock of these useful animals could be folded over these Cabbages, they would in feeding on them admirably manure the soil. Failing that, there seems no other resource but to cut the heads to pieces and plough or dig them in as manure, and certainly Potatoes will thrive admirably upon a green crop turned in as manure. Still, the market grower prefers to sell his crops and take home manure.

POTATOES.—Even for such an easily satisfied crop as Potatoes, it is evident that much of the ground is getting overdosed with manure, because the market grower, who works so much by rule of thumb, seldom employs any other than animal manure, and perhaps soot—an excellent thing, but lacking these elements which kainit, superphosphate, &c., give. The ground now being cleared of later Coleworts, and Turnips will soon be planted with early Potatoes, chiefly Beauty of Hebron, now the favourite early kind. The White Beauty is not so well known as it deserves, but without doubt it will be the favourite in a few years. Growers for market, because of the conservatism of the dealing trade, are very chary of changing old for new kinds.

SEAKALE—This root is not grown very largely below the Twickenham boundary, as it needs a rich, deep-holding soil, but it will eventually become more widely grown as the builder covers the soil Fulham way. It follows as a capital crop on soil somewhat overdone by Celery, but which has been deeply worked. Seed sown early in April in rows 2 feet apart will in such case give very strong roots the first season, and in less favoured soils really first-rate planting roots. Of course, the seedlings should be well thinned to 6 inches apart at least, and even wider, if intending to become strong; whilst yet young, where largely grown for the production of forcing roots, the weaker ones left are being trenched out, trimmed to lengths of about 6 inches, and laid in temporarily until the soil is dry enough to dig deeply, then they will be dibbled out at roomy intervals and will make fine roots by the winter.

RHUBARB—Old plantations of this useful root are being trenched out gradually, the roots clamped in sheds or cart-houses, or surrounded by hurdles and straw, and thus induced to make early stalks. Early Potatoes follow, helping during the season's cultivation to make the ground cleaner and fitted for other crops. Rhubarb invariably induces the growth of Couch or Twitch Grass, which it seems impossible to fully eradicate, even with all care. Although, no doubt, seedling Rhubarb plants would prove the more robust and profitable, and are very easily raised, yet there is some uncertainty as to their proving true; hence it is found safer to cut up and replant crowns from the forced roots, as in the second year these give an abundance of stalks, and usually break up rather the earlier for the previous forcing. When a moderate breadth of old roots is thus treated annually, an ample stock of clean ones is always maintained.

A. D.

Cinerarias.—From Mr. B. S. Williams come blooms of these, rich and varied in colour, round and smooth in outline, and large without being coarse; evidently a good strain.

Industrial Insects.—Robert Denn's. Murray, Albemarle Street, London.

SOCIETIES.

ROYAL HORTICULTURAL.

THE annual report for 1886 to be submitted to the anniversary meeting on Tuesday next has just reached us, and from it we extract the following: The council have been for a long time anxiously considering the arrangements which have now to be entered into, in order to enable the society to carry on the useful work on which it has been engaged during nearly the whole of the present century. While they cannot conceal from themselves that the society's connection with the recent exhibitions, and indeed with South Kensington generally, has been gravely disadvantageous to it in the prosecution of its legitimate work—the promotion of scientific and practical horticulture—it is obvious that the society could not establish itself in a new home adequate to its requirements without undertaking a very serious expenditure, for which funds would have to be provided. The council have therefore entered into preliminary negotiations with the Royal Albert Hall Corporation, and they are prepared to recommend to the Fellows that they should be empowered to enter into an agreement with that body on the following terms—terms which the council believe will leave the society practically independent, while providing sufficient accommodation for its wants. The Royal Albert Hall Corporation agree to give the Royal Horticultural Society—

- (a) The use of the conservatory for fortnightly and other shows.
- (b) Accommodation for the Lindley library and the meetings of the scientific, fruit, floral, and other committees.
- (c) Accommodation for the society's office and staff.
- (d) Admission to the Royal Horticultural Gardens every day, and to the Royal Albert Hall (unreserved seat) whenever open to the public.

The Royal Horticultural Society undertake the horticultural (but not the structural) maintenance of the conservatory, and of such limited portions of the gardens as may be occupied by the Royal Albert Hall Corporation, and to contribute an amount to be agreed upon towards the heating of the conservatory. It is distinctly understood that the Royal Horticultural Society will enter into any agreement it may make as an independent body, and that the society will have no connection whatever with the musical or other entertainments contemplated by the Royal Albert Hall Corporation. The latter body have intimated that at present they are not prepared to give the Fellows of the Royal Horticultural Society transferable tickets.

The auditors report as follows: "We much regret that two great disturbing influences have had a serious and depressing effect on the finances of the society in 1886; the first being the taking away the privilege of transferable tickets of admission and making them personal, which resulted in the resignation of a large number of Fellows, causing a reduction in the receipts of this most important part of the revenues to the amount of £850; secondly, the failure of the Liverpool Exhibition, which shows a deficiency over the receipts of £740, and, added to the loss from subscriptions, makes a total loss under these two heads of £1590, against which there is the asset of £300 for overdue subscriptions."

NATIONAL CHRYSANTHEMUM SOCIETY.

ON Monday evening last the annual general meeting of this society took place; the balance sheet and report were received and adopted. It was announced that for the first time in the history of the society three shows of Chrysanthemums had been held in one season, that the September and November shows were very successful, and that at the mid-winter exhibition of late varieties in January exhibits had been sent from all parts of the country. It was resolved that during the ensuing season three similar shows should be held. After the election of fifteen new members, applications were read from four provincial societies to become affiliated. The election of officers and general committeemen was then proceeded with, and upon the motion of Mr. Holmes it was resolved

that in future one-third of the members of that committee do retire annually in rotation. Arrangements have been completed with the Royal Aquarium Company to hold the exhibitions of the society there as hitherto, and the company have offered the following sums to be distributed in prize money, viz., £50 for the September show, £100 10s. for the one in November, and £50 for the show in January, 1888. The names of donors of special prizes and contributions to the prize fund were next announced. The classes in which the six Veitch Memorial medals are to be offered will be specified in the society's schedule. It was resolved that the preparation of the schedule for the current year be referred to a special sub-committee. The meeting was brought to a close after various suggestions as to alterations and emendations in the schedule had been made.

GARDEN DESTROYERS.

Destroying ants.—M. Dybowski states, in the journal of the French National Horticultural Society, that he has found sulpho carbonate of potassium a sure means of destroying ants when they are working among the roots of plants. A quart of this dissolved to ten quarts of pure water is found to kill them. If one watering is not effectual, two will be found a sure remedy. An important point in connection with the use of this chemical is, that it does not injure the most tender root. Ants being fond of making their runs in Box edgings and among the roots of hardy plants generally, where the use of boiling water is inadmissible, this recipe for their extirpation will be welcome to many. M. Dybowski also states that in glass houses they are most easily trapped by means of sugar-water, to which a little rum or brandy is added. They are so fond of this, that where they are at all numerous, the vessel containing the mixture becomes in a short time a mass of dead ants. They become stupefied by the alcohol, fall in, and cannot extricate themselves.—J. C. B.

Woodlice.—I find these to be destructive to Ferns; they hide in the crevices of the rockwork, commit depredations at night, and anyone not conversant with their habits might attribute the ragged look of his plants to other causes than the right one. The tissues of some of the leaves are eaten away until only the midribs are left, while other kinds seem to be unmolessted. When these troublesome pests get established in rockwork it is a tedious process to eradicate them. But in ordinary plant houses they may be readily destroyed by laying flat pieces of board or slate on the borders with Potato peelings placed under them. Under these boards they congregate, and may be destroyed by boiling water, or flower-pots with some hay in them and baited with a few pieces of Potato make good traps. In this way their numbers may soon be reduced. But, as in the case of all greenhouse Ferns, young fronds are now pushing up, it is of the utmost importance to keep these from injury; when young and tender, woodlice soon play sad havoc with them. A few choice specimens might be kept safe by setting them on inverted flower pots in pans of water. But where large numbers have to be dealt with, the only plan is to trap them, and when cleaning the houses in spring, a plentiful supply of boiling water should be poured into their hiding-places.—J. G., *Hants*.

The Eucharis mite. This mite does not confine its depredations to the Eucharis, but also causes the loss of many other bulbous plants, including Vallotas, Anemones, and Pansies. A very fine collection of these has had to be destroyed on account of being affected by this pest.

Names of plants.—*H. D.* 1. *Illecebra Brocklehurstiana*, *Chionodoxa pauciflora*.—*B. Kald.* The ordinary form of *Labisia* (moss).—*H. M.* *Agrostis* (moss).—*H. Names of fruits.—*F. D. (Horseshoe Heath)*.—Small Pear, Bishop's Thumb; Apple, Winter Pearmain; Large Pear Vicar of Winkfield.

WOODS & FORESTS.

YORKSHIREMAN.

FENCES.

If our forestry management is to be cheapened in the future we must begin with the fences, which are such a considerable item in forming new plantations, and the old quick hedge will have to go, being perhaps the most expensive to rear and keep in good order. Wherever one goes in England you find the hedges planted round plantations neglected and decayed, in many parts extensive gaps made up with stakes and bindings, the original hedge having entirely disappeared, while in other places it has never grown, owing to the trees growing over and smothering it. The worst place for a hedge is next to a plantation, unless you place it further off than you can afford to do considering the value of the land. Timber or iron supply the material for the plantation fences of the future, and the simpler and stronger these are the better. Unless we keep down the cost we shall have no fences at all nor woods either. On large estates a few men can get and rive as many stout Oak fencing stakes of any size necessary as will supply not only the estate annually, but the tenants at a cheap price. These, if driven in thickly enough with a rail on the top and stayed, will make a fence good enough to keep cattle out, and if the stakes are driven in thinner and wattled with bindings of Thorn, Hazel, Willows, or other underwood, they will answer better still. Such fences are not ornamental, but are rustic enough looking, and are as good as any fence needs to be between farm lands and the plantations. Dry stone walls are substantial, but expensive, and are the reverse of ornamental. Where stone is scarce they are out of the question. In these times when timber yields such a small return per acre fine fences cannot be afforded, nor have they ever been at any time necessary. I should not advise live fences, nor any other that cannot be easily and quickly put up with the timber of the estate or wire. A common piling of posts and rails—the latter nailed on—is perhaps one of the cheapest kinds of fence, that stands well and can be soon mended when it fails. It is a mistake to suppose that plantation fences require to be very high or very strong. Young and unbroken horses are perhaps the worst to fend against, but my experience of even these in large numbers in the parks where there are miles of slim fences round the woods is that a very insignificant barrier turns them unless they are being driven or frightened. It is a most uncommon thing to find either cattle or horses breaking through fences of any kind unless it be at a gap.

— In Northern England, at least one half of the live fences are, pure and simple, but a waste of valuable ground, a harbour for vermin to prey on the farm crops, and utterly useless for the purpose intended. It is no uncommon thing to see what are classed as fences, but which in reality are but a combination of stones, bushes, and neglected Thorns, taking up as much as 12 feet in width of the field in which they occur. A great mound of earth was thrown up, a few Quicks, Elders, Ashes, Willows, and whatever else of the nature of a hedge plant could be obtained planted on its summit, and the whole left for Nature to have her own way. Rabbits burrowed into the cosy earth mound and injured the roots, while gaps made by the farm stock were filled up by dragging a dead branch into them or placing a few stones on top of each other, and thus the fence was treated, until in the end it was neither a live nor dead one, but a combination of the two, and worse than useless for the purpose intended. I have seen and measured 9 acres of a farm that contained fences occupying fully one third of the total area, and had they been fences in the true sense of the word, less complaint might be made, but they were little else than field divisions, and expensive ones too. A well-managed and, of course, properly formed hedge should not occupy of itself more than

30 inches in width, and I am well acquainted with miles and miles of such fences that give but little trouble and are quite proof against the incursions of farm stock. Of course, in such cases as those just cited an annual trimming and cleaning of the fences is engaged in, while gaps or holes are filled up at once by driving a couple or so of posts into each and planting stout, well-rooted Quicks in the openings. Planting live fences on mounds is objectionable, unless, indeed, the soil is extremely damp, and even in such cases it is preferable to use some plants suitable for such situations and have the hedge on the level, for even with great care and attention the ridge or mound gets broken down and causes endless expense in repairs.

A. D. W.

PRICES OF FIREWOOD.

THIS is a factor affecting the use of wood as fuel. From what I have heard lately, wood must be cheaper than coal in some places, but here it is not, and I do not see how, in prosperous times when trade is brisk, wood can be cheaper than coal anywhere, except in remote districts. In this part of Yorkshire the cheapest firewood is small ramil, which is practically unsaleable, but on most estates it is prepared for lighting the fires in the house, and delivered at 3s. per hundred kids or small bundles, the labour only being charged. The next cheapest is cordwood, which is saleable for charcoal-making, and which cannot be collected and delivered for less than 14s. per ton; hence it is dearer than coal in a colliery district, and does not go nearly so far. Next to cordwood comes dead and sap rotten timber, which is also saleable, according to the length of time it has been dead and felled. As firewood, split and delivered, this costs between 20s. and 25s. per ton, and where the labour only is charged, it costs about 18s. per ton. Good Ash, Beech, and Oak would cost nearly £3 per ton delivered, and inferior woods a little less. Ash at the present low prices fetches from 30s. to fully 40s. per ton in the wood standing, large Oak more, and middle-sized and poles about 35s. per ton. Birch and the like a little less. These prices are for poles or small trees; for large planking Ash and large Sycamore the price is much higher. These prices are, however, sufficient to show that we here could not burn timber without gross extravagance: and, of course, where coal is dear, firewood will rate proportionately. Still it appears that a considerable quantity of timber is burnt in private houses where one would not expect it. I am informed by our steward that in some mansions so near the main railways as Huntingdonshire timber is burnt both in the kitchen and rooms for economy's sake. What kind of timber it is I do not know, but I am curious to learn under what circumstances it can be cheaper to use timber in preference to coal, unless it is wholly waste, and fires cannot be kept of such materials. With regard to the prices of timber above quoted, it must not be imagined that they are particularly remunerative prices. Some years ago prices were at least half as much more, but when the quantity of the timber sold from an ordinary estate in one year is considered, it may happen that the return per acre may be very small indeed. Indeed, as things stand at present and have stood for years, it takes good management to get 5s. per acre of clear profit from woodlands in England, but it is the fault of our forestry, and not our timber or our markets that it is so. S.

Tinning for shelter.—This is an anomalous proceeding, as described by "H." in his paper on shelter-planting. According to him, shelter belts that are not thinned soon come to an end, being swept away by the wind, as, according to "H.'s" reasoning, the thicker the trees are grown together and the fewer the branches they have, the more liable they are to be blown over. In the same way we suppose a ship under bare poles would be most likely to lose its masts in a gale of wind. This will not hold water. The stiffest of all tree belts are those that are left pretty crowded, especially on the windy side, and this

fact is so apparent everywhere, that one wonders to see the opposite opinion recorded. Recent storms of wind have shown it. On some of the best thinned estates in the south of Scotland, where all the Spruce trees are furnished to the ground with branches, owing to their having room, and which "arrest the progress of the wind," according to "H.," more trees have been blown down than anywhere else in these islands. I knew one belt in particular, consisting mostly of Spruces, in which not one tree was left standing. The reason of this is, that in thin belts every well-branched tree is exposed to the fury of the gale, and if the force of the wind is greater than the root-hold, over it goes. Only the crowded belts stand the storm. If the outside is pretty thick, it breaks the force of the wind, which goes over the top of the plantation or whistles through between the crowded, but bare trunks. "H.'s" theories are not derived from observation. We have a fine example here on an exposed ledge where the gales are fierce enough to prevent a horse and cart venturing at times. The belt is a mile long, and has never been thinned severely. Outside on the windy side the trees are more branched and stunted, but inside they are less so, and grow taller and taller till the other side of the belt is reached, owing to the increasing shelter and warmth. It is rarely a tree is blown over here, and the same thing is observable in all such cases.—Y.

HEDGEROW TREES.

THE two main qualities required in a hedgerow tree are, first, that the habit of growth be somewhat fastigate, and, second, that the roots have a downward tendency or are not inclined to run along the surface, and so impoverish the upper stratum of earth. Few trees, it must be admitted, possess these qualities in conjunction to any great extent, and I know of no one that does more so than the Cornish Elm (*Ulmus cornubiensis*). The branches of this tree are fastigate to almost as great an extent as the Lombardy Poplar, while the roots incline more downwards than to run along the surface, and are consequently not so impoverishing to the ground in the immediate vicinity of the tree. Other good qualities to be found in the Cornish Elm are its ornamental appearance and value of the timber it produces. It bears pruning well, and may be trained with a clean stem for, say, 12 feet from the ground without in any way detracting from its ornamental appearance, while to the fence on which it is planted such a method of culture is highly beneficial. Other valuable hedgerow trees will be found in the Plane, Sycamore, Black Italian Poplar, Birch, English Elm, Spanish Chestnut, Lombardy Poplar, Norway Maple, and Larch. The Sycamore is a valuable field or hedgerow tree, inasmuch as it does not occasion too great a shade when well managed, is not impoverishing to the ground in its immediate vicinity, produces valuable timber, and for ornamental appearance is well fitted to hold its own with any other tree cultivated in this country. Were it not for the almost valueless timber it produces, the Lombardy Poplar might be considered as an A 1 hedgerow tree, for barring this one fault it possesses every other quality that is necessary for a tree in such a situation. The Maples are valuable and should be used largely, while the English Oak, if a little care has been expended on its nursery management, more particularly in the way of pruning, must not be despised, which may also be said of the various other trees above mentioned.

A. D. WEBSTER.

Timber in Scotland.—The statement of "H." (p. 87), who seems to speak for the whole of "the south of Scotland," that "the reason you always get" for the thinning of young plantations being neglected is that "the trees are of no use as wood," and are only fit for shelter. "H." says there are not ten plantations in the south of Scotland that are properly thinned, and their prospective worthlessness as timber is the reason. Is this true? we ask foresters in Scotland, because if it be they have had more to do with it than anyone else. If it is not true, "H." had no busi-

less to say so, I do not myself believe the statement, unless the trees are of the wrong sort, and that is probable enough. So long, however, as it will pay to import timber from almost every part of the world to this country, it will pay to grow it at home; and where it does not do so, it is the fault of our system of planting for game, planting the wrong kinds of trees, and the extravagant management generally.—J.

Appearance of good timber.—It may interest "A. N." (p. 112) to learn that the best of theory and the Admiralty tests are at direct variance with his assertion to the effect that timber which "has grown the slowest, as shown by the narrowness of the annual rings, is the strongest." Our typical trees, Oak and Ash, for example, resist the greatest tension and impact when grown fast, in consequence of the fibre being longer and stronger. Timber dealers are familiar with this fact, especially in the case of the Ash, and will always give a higher price for clean quick-grown trees. It was a common opinion once that slow-grown timber was the best till the Government tests proved the contrary, and Lindley altered the theory to correspond many years ago.—S.

Age at which young trees transplant best.—It is necessary on some lands to plant tall-growing plants, but the general impression seems to be that the smaller the tree the better the chances of success. Some species will break from the base, and make a better trunk therefrom than from a stem to begin with 4 feet or 5 feet high. In the case of Firs, there can be no doubt about the advantages of planting very young trees, and the only objection to doing so is the nature of the undergrowth they have to contend with. Where Bracken abounds, as it does in vast tracts in some parts, there is no chance for small trees unless the Bracken is kept down, and to do that means doubling the cost of planting, or more; therefore, planting trees tall enough to get their tops above the Bracken becomes a matter of importance.—Y.

Thinning forest trees.—Thinning trees, like every other part of practical forestry, is good or bad according to the manner in which it is done. One class of foresters would help Nature to develop her productions, while another would leave her to develop them as best she can. Now there can only exist a definite number of trees on any given area; therefore, to prevent overcrowding, thinning becomes a necessity. Nature unaided has certainly yielded some grand productions in the way of trees; but is it not just possible that if man had assisted Nature to distribute her power, that these trees would have been still as great, that there would have been more of them, and that they would have been of more uniform growth? Indeed, there is the best evidence to show that such would have been the case. It will not do to pin one's faith upon that magnificent trunk just recently arrived from a natural forest abroad. Such examples teach us nothing as to what is best to be done in regard to home forest management; and to copy Nature (as has been suggested) in her plan of thinning would result in disaster and ruin as regards our woods. Moreover, we have an object in view in thinning, namely, the yield of the greatest amount of useful wood or trees on any given space. Therefore, it is my opinion that those who thin their woods, &c., carefully and regularly will best realise a maximum of profit.—J. F.

Preservation of timber.—Amongst the most efficient means of preserving timber are good seasoning and the free circulation of air. Protection against moisture is afforded by oil paint, provided that the timber is perfectly dry when first painted, and that the paint is renewed from time to time. A coating of pitch or tar may be used for the same purpose. Protection against dry rot may be obtained by saturating the timber with solutions of particular metallic salts. For this purpose Chapman employed copperas (sulphate of iron); Kyan, corrosive sublimate (bichloride of mercury); Sir William Burnett, chloride of zinc. All these salts preserve timber so long as they remain in its pores; but it would seem that they are gradually removed by the long continued action of water. Dr. Boncherie employed a solution of sulphate of copper in about one hundred times its weight of water. The solution was contained in a tank about 30 feet or 40 feet above the level of the log, through the tubes

of the vascular tissue of which it was forced by the pressure of the column of fluid driving out the sap before it at the other end of the log, until the tubes were cleared of sap and filled with the solution instead. Timber is protected not only against wet rot and dry rot, but also against white ants and saw-arms, by Bethell's process of saturation with creosote, a kind of pitch oil. This is effected first by exhausting the air and moisture from the pores of the timber in an air-tight chamber, in which a partial vacuum is kept up for a few hours, and then forcing the creosote into these pores by a pressure of about 150 lbs. on the square inch, kept up for some days. The timber absorbs from a ninth to a twelfth of its weight of the oil in this process.—A. N.

PLANTS FOR RAILWAY HEDGES.

In many districts of England railway hedges seem to receive much greater attention than many of those planted for the intersectional fencing of land. The plant generally employed for railway fences is the White Thorn, and a useful plant it is for such purposes, and now contracted for as regularly as the rails themselves. On some of the newly formed lines the varieties of Evergreen Hollies ought to be tried, particularly on those portions of a line running through extensive and well-regulated policies in sight of the mansion. In some cases the proprietors may be induced to pay the extra difference of the plants, while the after-keeping will be much the same as the ordinary Thorn hedge. In all peaty districts the Spruce Fir will make an excellent Evergreen fence. It will cover more ground than the Holly; but in mossy situations this extra land will be found of less value. In sandy places, and particularly those near the seashore, the Sea Buckthorn (*Hippophae rhamnoides*) will be found an admirable substitute for Thorns to form hedges. If it should ever be required to make at once an impenetrable live fence, the Hornbeam (*Carpinus Betulus*) will be found the most suitable, and for this purpose clean grown sapling plants, 6 feet or 7 feet in length, ought to be procured. After the ground has been properly trenched and prepared, the plants should be put in, two together, at every 10 inches or 12 inches, according to the thickness or length of the saplings employed, giving one an inclination to the right and the other to the left. After being trodden in firmly, commence to plait all together, taking one set of the plants the one way, and the other set contrary, interlacing them at an angle of 45°. It will be necessary to tie them at top with a piece of wire or rope yarn, and also at several points near the bottom, to keep them in position till they adhere to each other. To facilitate the union, although not absolutely necessary, it will be desirable to take a thin cutting off the bark of several, particularly where they approximate. Shortly afterwards they will grow together, and form an impenetrable net-looking fence. From the pressure caused by the plaiting, they will throw out numerous shoots along the stems, which will continue to work in and fill up the interstices. In time the whole length will become an impenetrable mass, all engrafted together, and will bear cutting in like any other hedge. Numerous other plants will be found in nursery establishments suitable for such purposes, as the Hazel, Elm, Ash, Beech, Laburnum, &c. Such hedges can be made of any height, depending entirely on the length of the saplings employed. When not in leaf, they will be found extremely ornamental and agreeable to look on, and therefore worthy of encouragement, particularly when standing on a level with the rails. If it should ever be wanted to plant such hedges so as to render them useful as well as ornamental, particularly on lands slightly elevated above a damp surface, in such places Willows could be profitably employed, and the annual cuttings taken from them would yield a considerable revenue. Besides, when such plaited hedges are cut for profit, they are more likely to be kept in order than Thorn hedges, particularly when they run through lands which would be profitably employed for the growth of Willows. When planting Willows for such purposes, they could be inserted either as growing plants or cuttings—the latter will be preferable, provided the strip of ground has been properly prepared for them. They should be placed 12 inches apart, and

during the first thinning the strongest shoots should be left for plaiting. After the plaiting has been successfully accomplished, all after shoots could be removed for basket-making purposes. N.

TREES OUT OF PLACE.

How often do we observe trees planted in situations that would almost cause one to imagine that little thought or consideration had been previously given as to the amount of space they would require for extending their growth, or the size which they would ultimately attain. Everywhere do we find fine old Cedars, Larches, Cypresses, evergreen Oaks, and even Poplars, Yews, Horse Chestnuts, Elms, and other large and ornamental trees planted closely to old castles, mansions, halls, &c.; and still such misplacement is continued. Neither is this always the planter's fault, for a lady or gentleman may purchase in a pot a plant of some newly introduced tree, and, without consulting anybody, choose some conspicuous spot for the reception and future development of their little favourite. The planter is then informed of their decision, and although he may remonstrate, his endeavours to frustrate their purpose often fail. This, therefore, is frequently the reason why we find stately and handsome trees planted so near mansion houses. During their infancy all goes on well; but as they grow older, they increase in stature, as a matter of course; and, if not removed, they ultimately attain dimensions which quite unfit them for the situations they occupy, sometimes darkening the house, and at others obstructing a free view of the distant landscape. Where it is desired to have choice trees grown to advantage, a piece of deep, well-prepared ground should be selected purposely for them, in what may be termed an arboretum, where, when once planted, they should be allowed to remain uninterfered with.

When the *Sequoia* (*Wellingtonia*) *gigantea* was first introduced into this country, numbers of it were placed under my charge, and, with careful treatment and with regular and large shifts, to my great satisfaction, they soon made fine luxuriant plants. Proud of my success, I wished to provide them with a permanent situation where they would be well sheltered, have plenty of room, and enjoy a considerable depth of good soil, and with that object in view I consulted my employer about them, when I learned with astonishment that the place fixed upon for their future development was where they now stand, viz., in a situation exposed to the sea, on the poorest ground on the estate—a solid bed of gravel! I determined, however, to make the best of such adverse circumstances; I gave each tree a space of 60 feet, trenched the station on which it was to stand 10 feet in diameter, and enriched it with surface soil and whatever other suitable material I could obtain, thoroughly incorporating the whole and fashioning it into a gradually sloping mound 5 feet high in the middle. At the time of planting, a railway was to have been made through an adjoining field, the turfy surface of which I intended to secure for the purpose of filling up the hollows between the trees to a height of 6 feet or 8 feet, thus converting their present mounds into little valleys; but in this I was afterwards disappointed. In planting, the centre of each mound was cast out and a load of good open healthy soil was introduced, in which the plants were inserted. They were then mulched, and the operation was finished by placing a rustic cage 6 feet in diameter around each young tree. In the arboretum one tree was planted and did remarkably well, when, owing to an addition of 7 acres or 8 acres of new ground being made, it, together with others, had to be removed. I then planted it on a spot filled up with many hundreds of cartloads of healthy old bank soil mixed with turf, thus forming a depth of 8 feet of excellent soil, in which it will find room to grow and luxuriate for the next five hundred years at least. There it remains still, a noble example of what may be expected of this tree when planted under favourable circumstances.

T. B.

The three undermentioned pieces of timber were measured by the slide-rule:—

No. 1,	14 feet long,	104 inches round
No. 2,	10½ "	80 "
No. 3,	12 "	78 "

These measurements were taken round the middle of the tree.—T. Y.

No. 795. SATURDAY, Feb. 12, 1887. Vol. XXXI.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—Shakespeare.

ROSE GARDEN.

T. W. GIRDLESTONE.

WHAT IS A GARDEN ROSE?

OF all the myriad times the term garden Rose is used in speaking and writing of Roses, or in Rose books and catalogues, in how many instances has the expression a definite or at all exact meaning? and were any two persons ever known to employ the term in a precisely similar sense? One grower talks of garden Roses as if they were things unknown to the wicked exhibitor; another proclaims the best exhibition Roses (deplorable term!) as being also the best garden Roses. One man will allude, with that half-pity born of contempt, to an exhibition Rose as a thing to be inspected only under canvas or set up in a green box, and not to be conceived as growing in the garden; and his neighbour will always be recommending for garden decoration the varieties with which he has won most prizes. And while, from the tone of the first, it might be inferred that raisers of Roses have produced nothing to beautify our gardens for the last thirty years, the latter would give the impression that it is only during this period that Roses worthy of a garden have been raised and distributed. That there is something in this diversity of conception is evident from the fact that the National Rose Society, in offering prizes for garden Roses, does not define the term, but evades the difficulty by merely excluding from the class all varieties enumerated in a certain arbitrary list of so-called exhibition Roses. This term is itself an unfortunate one; for either any Rose that is ever exhibited is an exhibition Rose, or it is not; if it is, then a large proportion of what are commonly called garden Roses are really exhibition Roses; if it is not, then its availability for exhibition does not constitute an exhibition Rose!

It has been suggested as a definition that a garden Rose is one which can endure without serious injury somewhat excessive drought and cold, and which will flourish with little or no special culture in a variety of soils and for a considerable term of years. But this sounds like the definition of a Rose for a wilderness rather than for a garden, and though we may well be thankful that there are Roses that will grow themselves, yet it is the ambition of everyone who gardens to bring to perfection things which, if left to themselves or not carefully tended, are liable soon to lose their attractiveness. Assuming, therefore, that a moderate amount of pains and care will not be grudged by those who are desirous of enjoying the beauty of the queen of flowers in their gardens, there is no imaginable reason for making the definition of a garden Rose such as to exclude the best of the varieties most commonly exhibited, and if these are admitted, the value of the expressions "exhibition" and "garden" Rose as distinctive terms is not obvious. Take, for instance, the two varieties La France and Madame Gabriel Luizet; both are hardy and vigorous. With a certain amount of skill and care both will make large plants and produce an abundance of beautiful flowers in a variety of soils and situations. The one is well known to be, and the other now seems likely to prove, a thoroughly autumnal bloomer, and therefore both might be considered essentially desirable

garden Roses. But, on the other hand, it would probably be safe to say that throughout the season there is hardly a Rose show at which these two varieties are not conspicuous, and they are undoubtedly both among the twelve best exhibition Roses.

It is obvious, therefore, that the definition of a garden Rose cannot be made to exclude exhibition Roses, and if it include them, it is no longer a distinctive term. An expression which means so much means nothing; and if both terms could be entirely abolished, a great amount of misapprehension would in all probability be avoided. No doubt a good many people who do not care to exhibit, but merely want Rose trees that will make attractive objects in the garden, are deterred by the term "show" Roses from employing some of the most beautiful and valuable varieties under the mistaken impression that these are of no use except to the exhibitor; and, again, some persons regard the epithet "garden" Rose as a positive stigma on a variety, instead of as the highest distinction.

It is not easy to see that there is any essential qualification for a garden Rose further than that it should have sufficient constitution to be able to form either singly or in a group an attractive object in the garden. The more freely and frequently it flowers, of course, the better; and, except in the case of climbers, the flowers make a more brilliant and striking effect if carried upright on the plant rather than pendent. This would include varieties of all classes, and the less that is heard about exhibition Roses and garden Roses as such the better. If writers and catalogue makers would make a point of not employing either term, they would both soon drop out of use, and with them perhaps the absurd notion still sometimes entertained that Roses which produce flowers sufficiently perfect to win prizes at exhibitions are thereby unfitted for making a display in the garden. Anyway, if the term "garden" Rose is to be retained, there is undoubtedly wanted a definition.

PRUNING INDOOR ROSES.

ACCORDING to my experience, indoor Roses are rarely pruned properly, the operator being too much afraid of overdoing it. The Teas are most neglected, or, if I may so put it, are the worst used in this respect. Only last week I saw two houses in different gardens nearly filled with Tea Roses in pots that evidently had not been pruned at all, those in charge preferring to let them break naturally. In both cases the plants were old and fairly strong, and doubtless will produce abundance of bloom, but this will be small, while the plants will be getting still weaker. I hold that all should be pruned, the spray being cut hard back, or to the first joint, and the remainder to the second, third, or fourth joint, according to their vigour. Spray is quite useless, but this and the other weak growth will break more strongly if hard pruned, and, other conditions being favourable, the plants will improve instead of gradually becoming rubbishy and worthless. Whoever saw young shoots on Teas too strong to flower properly? It is the weakly growth that refuses to flower, not the strong shoots, as these if too rank to produce a single bloom will branch and yield several. A Tea Rose, to remain in a profitable state, ought to be constantly pushing up suckers from the buried stem, and, unless pruning is resorted to, these will not often be forthcoming. It must be understood I am thinking about and treating upon own-root plants, these only, in my estimation, being suitable for pot culture. We certainly frequently have a few worked pot plants which are pruned similarly to the others, but they are bought in for the purpose of affording cuttings early in the spring, after which they are turned

out. Pot plants usually give a succession of blooms, being encouraged to break afresh two or three times in the spring, and they frequently endeavour to flower again in the summer. We are not constantly pruning the plants, cutting the buds or blooms being all that is necessary after the early winter shortening back. It is then when we cut back to near where they were last pruned, there usually being several back buds that did not push out below where the first bloom was cut. Thus pruned and otherwise well attended to, the plants can long be kept to a useful size. The youngest plants, or those struck in the previous spring, require little or no pruning, and these we find the best for flowering in heat during the winter. Those trained on the roof, with the exception of *Maréchal Niel*, also require to be pruned early in the year, or they soon become crowded and dirty. We thin ours out freely, and shorten back all the young growths, much as advised in the case of pot plants, and I may safely say no one has much better crops of *Homère*, *Safrano*, *Comtesse de Nadaillac*, and *Devoniensis* than we have. These are all on the Brier stock, are planted outside, and brought inside through the roof. They bloom during at least nine months in the year, and every season we use the knife freely, or rather scissors, for these are the best for pruning Roses. All useless spray on the *Maréchal Niel* should be cut away, the medium-sized and strong growths being laid in to their full length, good blooms being forthcoming from nearly every joint. When the plants give signs of being somewhat exhausted, or when no strong shoots are pushed out from different parts of the leading branches, hard pruning must be resorted to directly after the flowering period. If all the flowering branches are cut hard back, the plant should form another lot equally strong, or perhaps stronger, than these, and which will flower the following season. It is the neglect of this precaution that sometimes leads to an early break-down, but in all fairness I must add no amount of pruning or any other renovating measure will long save those with badly cankered stems. Hybrid Perpetuals in pots ought to be pruned exactly the same as those growing in the open air. All spray should be cut hard back, medium-sized shoots to the second joint, and the largest, say about the size of a lead pencil, to the third or fourth joint. This ensures a fairly strong, floriferous break, also plenty of back-growths constantly pushing out, and which tend to keep the plants dwarf and well furnished. W. I.

Planting Roses.—On this subject Mr. George Baker, of Reigate, a skilful Rose grower, writes as follows: A few general directions should in all cases be observed. It will become your first duty to see that your ground is in a proper state to receive your plants. The soil should be neither wet nor dry, and the earth should divide well, and intermingle with the fibres of the roots readily. We must be careful in treading in the plants; it is evidently injudicious to plant on a retentive soil at a time of rain, though on lighter grounds the work may be done safely, even though you have gentle showers. I question whether sufficient care and time are given to the mode of planting and arranging the roots in the ground; this is often carried out in too hurried a manner. Before placing the plants in their position, they should be carefully handled, and the roots well looked over, and all broken or injured portions removed; then spread out in a radiating direction, as far as possible, so that the rootlets may take up the aqueous and other fluids readily. It must be remembered that it is not the thick substances of the roots that gather up the food for the support of plant life—they serve an important end in firmly fixing the tree in the soil—but it is the minute root fibres to which the plant owes its nourishment. The roots, therefore, should be well spread out, and never packed up together, and planted down in a straight direction. Caution must be further observed that you do not plant too deeply in the soil. I suspect mistakes of this kind often occur. Mr. G. Prince, of Oxford, I remember once found fault with me in this re-

spect, and advised on the seedling Brier, that the union should be just above the ground line, but he emphatically called our attention to regard the same depth at which the plants had been previously grown. This latter part of his advice is in like manner urged by most of our practical nurserymen, though some of them are in favour of placing the points of junction beneath the soil, which they think will give the plants a double chance. No doubt, with the Manetti stock, you may plant deeper than with others.

Rosa polyantha grandiflora (Bernaix).—A new variety of this charming species is now being sent out by M. Bernaix, similar to, but with rather larger flowers than the type. In France, however, where *R. polyantha* is highly prized as a stock, especially in the seedling form, the great merit of this variety *grandiflora* is held to be its freedom in producing seed, the type not being a very prolific seed-bearer. It is stated also that the seed germinates very rapidly, and if sown on a hotbed in March, the seedling plants may be grafted the same autumn.

SHORT NOTES—ROSES.

Rosa pisocarpa.—This is a valuable and pretty Californian Rose and one that, judging from what we saw at Kew, is particularly well adapted for planting on rockwork. The flowers are of a desirable rose colour, and succeeded by bright red fruits; while the whole plant is of low straggling growth with dark green, evenly crested leaves.—A. D. W.

Old double yellow Rose. I should feel most grateful to anyone who could tell me where to procure the true *Rosa sulphurea*. I have written to all the leading Rose nurseries without success. I have even given a standing order in two cases of more than a year, and am now told it cannot be sent to me from them, although it is in their Rose catalogues.—F. W. Y.

PROPAGATING.

TUBEROUS BEGONIAS.—These are increased by two different methods—viz., seeds and cuttings. By this last mode alone can individual varieties be propagated, as seedlings will vary to a greater or less extent; yet a pinch of seed sown now, if it be saved from the best varieties, will give but little trouble, and yield a good display of bloom during the summer. All tubers that have been resting during the winter, and are now required for propagating from, should be shaken out of their old soil (if that has not been already done) and repotted in good open compost. Then, if placed in a gentle heat and under conditions favourable to growth, they soon push up shoots which are available for propagating purposes. In removing a shoot required for cuttings, it should not be pulled out at the base, but cut off with a sharp knife above the bottom joint, thus leaving a nucleus from which other shoots will in time be pushed forth and form the future plant. If started thus early in the season, there will be ample time to grow the parent plant into a specimen, even after it has yielded a crop of cuttings. Should, however, a few weak shoots be pushed up around the main stems, they may be separated quite close to the tuber, as they will not add to the effectiveness of the plant if allowed to remain. The separated shoots being now ready may be treated in the following manner: Cut them off clean at the bottom with a sharp knife, but it is not at all necessary to leave a joint at the base. Then insert the larger cuttings singly in small pots; the smaller ones may be put around the edge of a pot about 4 inches in diameter. A soil consisting of loam, leaf mould, and silver sand, the whole sifted fine, is very good for the reception of the cuttings. If they are kept fairly close, in a temperature of 65° to 75°, they soon root; but precautions will need to be taken against decay, as, from their soft and succulent nature, they are rather liable to damp off if kept too close or the soil is too moist. There is another way of increasing this class of Begonias, which can, however, only be followed in exceptional cases, and that is, some tubers assume a flattened shape, and shoots are borne from several different places on the surface thereof. When this happens, and the shoots are about an inch long, the tuber can with a

sharp knife be divided into as many pieces as there are stems, and if then potted they will grow away without any check. With regard to seed, it must be gathered just as the pods commence to open, and kept during the winter in a dry place. The seed may be sown in pots or pans, but whichever is employed must be perfectly clean and thoroughly drained. This done, they can be filled to within a quarter of an inch of the top with light vegetable soil, consisting of three parts well decayed leaf-mould, quite free from any signs of fungus, and one part loam, with a liberal admixture of silver sand. The compost must be sifted moderately fine, and pressed down perfectly level for the reception of the seeds. After the pots are filled with soil a thorough soaking of water through a very fine rosed water pot should be given, and while the surface is still moist the seed must be sown thereon. The principal thing to guard against in sowing such minute seed as this is to take care that it is not sown too thickly, for when on the surface of the soil it is scarcely possible to discern it, and if it has not sufficient space allowed it, many will soon after germination damp off. The seeds will adhere to the moistened surface of the soil and need no covering, except a pane of glass laid over the pot. When sown a good place for their reception is a shelf in not too dry or exposed a position in the stove, as germination then soon takes place, and directly the young plants make their appearance the glass must be removed. This practice of covering any seed pots that contain very minute seeds with a pane of glass is a beneficial one, as it prevents the surface becoming too dry, but in one respect great caution is necessary, for the sun must on no account be allowed to shine upon them, as the confined space will become very hot and the young plants be sometimes quite roasted up. A second point to which attention may be specially called is, that after the removal of the glass, cutting winds or draughts of all kinds must be especially guarded against. When the young plants begin to get crowded, or if any signs of decay make their appearance amongst them, they must be pricked off, using for that purpose the same kind of soil as that recommended for sowing the seed. The young plants are very fragile and by no means of rapid growth during their earlier stages, but afterwards they grow much more quickly.

CARPENTARIA CALIFORNICA.—This, the subject of a coloured plate in a recent number of THE GARDEN, is not difficult to propagate, yet at the same time one or two points require to be borne in mind when desirous of increasing this handsome shrub. As our plants are by no means large, I have not been able to try what measure of success would attend cuttings put in the open ground; but a little after midsummer I took some of the young shoots that were getting moderately firm at a length of 4 inches to 5 inches, and put them in a pot of light, sandy compost. They were placed in a frame fairly well protected from the sun's rays and the lights kept close, for it is used during the summer as a propagating case for all kinds of plants. As the leaves have not much substance the cuttings were, in addition, covered with a bell-glass, the result being a great success, but unfortunately, though they were potted off, several perished during the winter from damp, which is very liable to attack them when small, in the heavy atmosphere inseparable from a cold frame during some part of the winter. Since this I have wintered them for the first season in the drier air of the greenhouse, and by the second year they are quite safe, even if confined in pots and wintered in the frame.

AMONG THE DIFFERENT SPECIES OF ASPARAGUS now cultivated for the sake of their ornamental properties, by far the most popular is that known as *plumosus nanus*, the delicate flat, frond-like branchlets of which are admired by all. In the absence of seeds, which are rarely obtainable, the propagation of this plant is effected by division of the roots, and the present is a very suitable season for the purpose. The plants that are to be divided

must be turned out of their pots and the soil shaken from the roots. A very good way to clear the soil from the roots without injuring them is to wash away the ball of earth in a tub of water, as if carefully done, not even the slightest rootlet will be damaged. The plants may be divided into as many pieces as there are separate crowns, and in some cases it will be necessary to use the knife for that purpose, but in doing so care must be taken not to cut off any of the shoots, as the underground portion is not unfrequently much curved, and appears, unless very closely examined, to spring from a source other than it really does. After division the plants must be potted into small pots, and, if possible, plunged in a gentle bottom-heat and kept rather close till root action recommences.

OTHER KINDS OF ASPARAGUS may be increased in the same way, but in the case of the low-growing *A. decumbens*, the operation is best performed in the autumn before growth commences, as this species is not evergreen, but rests during the latter part of the summer, and recommences growing in the autumn. Some kinds of *Asparagus* again, notably *plumosus* and *tenuissimus*, will strike root readily from cuttings, notwithstanding the assertions that have been made to the contrary. The cuttings are simply formed of the young branchlets taken off at a length of about 4 inches, and dibbled into pots of sandy soil. They will have to be kept in a close propagating case, and so treated will soon form a base from which shoots will push up, and in time small tuber-like masses make their appearance. Though a very good time now for division of the roots to be carried out, cuttings will succeed better if put in about a couple of months later. In the case of seeds of any of these kinds being obtainable, they should be cleared from the pulpy matter surrounding them and sown without delay, for if kept out of the ground for a lengthened period, they often lie a long time before germination takes place. T.

Cucumbers and Tomatoes from cuttings.

—The rule is to raise Cucumbers and Tomatoes from seeds, and in the case of new varieties when a packet only contains a very few seeds, and some of these not perfectly sound, the plants secured are not numerous. In fact, I have seen and heard of only one plant being raised from a 1s., 2s., or 3s. packet of seed, and when this happens cultivators are apt to think that they have paid dearly for their stock, but if we can secure one plant of a new Cucumber or Tomato, I care but little for mere seedlings, as it is quite an easy matter to propagate them from cuttings. We have recourse to this plan in the case of all new varieties, and often also in that of many old ones, as I am of opinion that plants from cuttings fruit sooner and more freely than those from seeds do. Many seedlings of both sorts rush up with a long strong stem, and blossoms do not appear until a considerable amount of growth has been made; whereas, plants from cuttings are dwarf from the first, and generally fruit a few inches from the ground. We do not trust to reproducing a favourite variety of Tomato from seed; a few cuttings of it are rooted in autumn, and these serve as stock plants to supply dozens of cuttings in spring. This is an excellent way of getting up a quantity of robust and fertile Tomato plants, and if this plan was generally adopted it would be found to give satisfaction. We hardly ever sow seed of Cucumbers after the first few plants are raised, as when the shoots are being pinched back the points are stuck into the soil round the margin of the mound of soil in which the plant is growing, and in that way they root freely and can easily be transferred to other quarters. As to the process of rooting cuttings generally little need be said, as it is as easily and simply done as securing a root to any ordinary soft-wooded plant.—J. MUIR, *Morgan, South Wales.*

SHORT NOTE—PROPAGATING.

Bouvardias.—It may not be generally known that *Bouvardias* may be propagated from the old wood. In a case which came under our notice the other day, some pieces

last year's growth had been put in by way of experiment and treated in the same way as ordinary cuttings, the result being a very fine lot of young rooted plants.

Propagating in sawdust.—Cuttings of such plants as Crotons, Dracenas, Pandanus, &c., will root in nearly anything if kept close and warm; for instance, I placed some time ago in a propagating house a wood frame, filled it with sawdust to within 6 inches of the top, and as soon as it was warmed by the bottom heat, I inserted the cuttings in the sawdust, which was well watered. A sash was placed over them, so as to keep them perfectly close, and with a little attention as regards moisture and shading from the sun, they became rooted in the short period of ten days. They were then lifted and potted in 3-inch pots and plunged into bottom heat again. As the young roots are very tender and easily broken, great care must be taken when they are being lifted and potted. The soil in which they are to be placed should also be warmed to about the same temperature as that of the sawdust from which they were taken. As a rule, I have found this to be a surer and much quicker way of striking cuttings than that of putting them singly in 2½-inch pots, but even in that case a great advantage is gained by filling the pot with prepared soil, which should consist of good loam, leaf-mould, and sand. The hole for the cuttings should be entirely filled up with sand. When the cuttings are inserted, plunge them into a good bottom heat, where they will quickly root if kept moist and shaded.—C. COLLINS, *Howick, Leisby, Northumberland.*

FERNS.

W. H. GOWER.

TWINING FERNS.

PROMINENT amongst these are the Lygodiums, a class of Ferns that are both elegant and interesting on account of the variety of tints of green which their fronds assume. The latter continue to grow from year to year, and thus extend to an indefinite length, forming dense masses of desirable greenery when trained upon wires or upon pillars, whilst the fact of their withstanding exposure to full sunlight adds greatly to their value. They are not only effective, too, but extremely useful treated as rafter or roof plants, as they thus afford shelter for shade-loving kinds below them. Lygodiums are widely distributed throughout the Tropics, and their fronds vary considerably in form even upon the same plant, a circumstance which renders the task of defining a species extremely difficult. Ferns belonging to this genus have a robust constitution and are vigorous growers, thriving equally in a house in which there is a high temperature and in cooler situations; nor are they over-particular as to soil, succeeding either in peat, leaf-mould, or loam. An admixture of these in equal parts is, however, most likely to produce the best growth. Lygodium scandens, L. flexuosum, L. polystachyum, L. japonicum, and L. venustum are all handsome and distinct forms of climbing Ferns.

Davallia parvula.—This beautiful little Fern, perhaps the smallest of the genus, is a native of Singapore and Borneo, a full-sized frond and stipe being seldom more than 3 inches in height. Its rhizomes are about the size of ordinary whipcord, and are clothed profusely with short ferruginous hairs. The fertile fronds are much smaller in their divisions than the sterile, and when the plants are well grown, the colour of the fronds is a very dark green. In growth it is rather slow, taking some few years before a patch of about a foot in diameter can be obtained. To succeed in the cultivation of this species, it should be grown under a bell-glass. When the plant is in a thriving condition, it is better not to disturb the roots in repotting, but simply transfer it, together with its pot, into another pot or pan, filling this up to within an inch or two of the rim with broken

crocks and sandstone, placing above this a layer of fibrous peat mixed with some sand and pieces of the sandstone. Should vapour condense on the fronds, the bell-glass should be taken off for a hour or so. With this treatment, and placed in a temperature from 60° to 65°, success is certain.—W. H.

D. alpina is another Bornean plant, growing from 4 inches to 5 inches in height, and of a darker green. The fronds are deltoid in shape, belonging to that section with pinnatifid, barren fronds. It thrives under similar treatment to the above. The bell-glass should not rest close on the soil, but be raised a little all round the pot or pan.—W. H.

** We have also seen both these beautiful Ferns thriving admirably on the stems of Tree Ferns, and in such situations they are very effective.—ED.

HARDY FERNS.

THE Parsley Fern (*Allosorus*, or *Cryptogramma crispata*), undoubtedly one of the prettiest of all our native Ferns, is also one of the very few which retain their characters perfectly constant; notwithstanding the enormous quantities in cultivation, no deviation from the species worthy of record has yet been noticed. It remains as it was years ago, simply the Parsley Fern. The plant,

Parsley Fern.

which seldom exceeds 5 inches to 6 inches in height, appears particularly fond of a cold climate, and is found wild in the north and west of England, at Tenterfele, near Kendal, in Westmoreland, in Rutlandshire, and at Borrowdale, in Cumberland, also in Wales, on Cader Idris, in Merionethshire, and on Snowdon, in Carnarvonshire. It is equally plentiful in the Highlands of Scotland, grand masses of it having from time to time been gathered in an old quarry in Perthshire. It is essentially a deciduous kind, losing its fronds about the end of October, and starting into growth again about the beginning of May. There are two totally distinct kinds of fronds—one barren and the other fertile, both of which are abundantly produced from a short-tufted root or caudex, which lies horizontally just beneath the surface of the soil, and produces a great quantity of very minute fibrous rootlets. The fertile fronds are considerably taller than the others, which are very much appreciated for bouquet and button-hole making, and produced as a second crop of foliage later in the season. Their spores ripen and scatter themselves in their native state about September, after which the foliage begins to die down, the barren fronds remaining on the plants the longest. Although often found growing in exposed situations, it delights in a cool, moist, and shady spot, and is specially adapted for a quiet nook in some well-constructed

rockery; it should be planted in a mixture of loam and peat in about equal parts, with the addition of bricks broken into small pieces, but care should be taken at the same time that no lime enters the compost, as it, as well as smoke and gas, is highly injurious to it. It may be propagated by seedlings, but this is a slow and tedious process; the more so as it is readily increased by the division of the crowns in the spring months just before its growth commences. This little gem also grows luxuriantly in the greenhouse, under the shade of Vines, or in a cold pit. When planted in the rockery out of doors or in a border, a little protection in the shape of a handful of leaves or litter may with advantage be given to it. S. G.

CORBULARIAS AND THEIR DISTRIBUTION.*

CORBULARIAS of late years having become popular decorative plants, the whole of the known forms being now introduced to cultivation, I think that a few notes on their characters and geographical distribution, mainly derived from my own observations, may be acceptable. Although the greater number of the species of *Narcissus* have a wide geographical range, many of them spreading over the whole area occupied by the genus, the subsection *Corbularia* presents a contrast in the limited and compact area it occupies compared with the wide ranging of the entire genus *Narcissus*. The Spanish Peninsula is its metropolis, and beyond this its extension is very limited. It has a range of about 10 in latitude, from 35° to 45° north, and 12 in longitude, from 9° west to 3° east. Forms of *Corbularia* are to be found throughout almost the entire Spanish Peninsula, and they extend sparingly beyond the Spanish frontier into France, and along the North African coast from Tangier to the longitude of Algiers. The most northern recorded habitat is near Bordeaux, and the most south-eastern at Guet es Stel, 150 miles south of Algiers, where I gathered *Corbularia monophylla* in the spring of 1873. *Corbularias* do not occur in the Balearic Islands. The general impression left by the careful study of all the forms is that they are merely connecting links of one variable species which is undivisible by any well-marked boundary lines, and however different the extreme forms may appear, they are connected by insensible gradations, between which there is no definite demarcation.

FLOWER COLOURING.—Every form of *Corbularia* is self-coloured, and however much the forms and species vary in shade, the segments are invariably of the same colour as the corona, except that they are externally green, and the bicolor forms, such as occur in almost every other section of *Narcissus*, are never found in *Corbularia*. The filament is also invariably of the same colour as the corona and segments. We find, however, two or three distinct sets of colouring, viz., white, primrose-yellow, and orange. I say sets of colouring, because, excepting the white, the other two colourings, primrose-yellow and orange, run through, as it were, in duplicate the entire series of forms, however variable they may be in stature—*q.*, we have large primrose-yellow forms and large orange forms, small primrose-yellow forms and small orange forms, and in the same colour duplicates of every size. I have felt inclined to give the white *Corbularia monophylla* from North Africa a separate sort of specific rank from its invariable colouring of a kind that I was not aware occurred in any other form; but I have been somewhat shaken in this conviction by Mr. Tait's discovery near Oporto of a white form of *Corbularia nivalis*, the flowers of which are normally orange.

HABITATS, ALTITUDES, AND DISTRIBUTION.—The range in altitude is from near the sea-level to heights of from 6000 feet to 7000 feet, and my observations show that there are no strikingly prevalent highland or lowland forms, many of

* Notes on the geographical distribution of *Corbularias*. A paper read before the scientific committee of the Royal Horticultural Society on Feb. 8 by George Maw, F.L.S.

them having wide ranges in altitude. The habitats are generally moist boggy places. The forms are never intermixed, each occupying a distinct habitat; indeed, I have only met with one case in which two different forms grow in proximity, and in this instance they were not associated, but occupied separate portions of the mountain pasture. I shall perhaps be able to more clearly express the facts I have generalised by describing as an itinerary through Western France, Spain, Portugal, Morocco, and Algeria, mostly from my own observations, the successive forms of *Corbularia* that would be met with in such a tour. Commencing at Bordeaux; soon after leaving Bordeaux Station, the moist, healthy places in the Landes are at frequent intervals bespangled with the large sulphur-yellow form, which is also seen occasionally by the sides of the railway as Bayonne is approached, and the same large pale form is frequent near the sea level in the neighbourhood of Biarritz. The following localities in France on the borders of the Western Pyrenees may also be enumerated: Gradignan and Teste near Bordeaux, Agen, Dax, heathy places on Mount Olivet and the Palombiers above Bagnères de Bigorre, Tarbes, between Bagnères de Bigorre and Savoy; sandy places—Tiple near Fumel, Prades, Villefranche, Morlass, Pau, and between Biarritz and Cambo. It is also abundant on Monte de la Haya at altitudes of from 2000 feet to 2400 feet, and on other mountains on the Spanish frontier near Irun. A small, pale yellow form has recently been found near Biarritz. Passing into Spain, we find on the limestone hills of Pancorbo, at a height of 3000 ft., a form somewhat different to that prevailing in Western France, with small, bright yellow flowers on a long scape. Turning northwards towards Leon, the moist places within sight of the railway are golden yellow in April with a small orange form; and a still smaller orange form, approaching *nivalis* in character, is abundant near Busdongo, at an altitude of from 4000 feet to 5000 feet on the pass over the Asturias. Descending the north side of the Asturias, the same large pale yellow form which prevails on the north side of the Pyrenees in Western France again presents itself in moist meadows near Oviedo, near Lugones, and between Oviedo and Gijon; and in the immediate neighbourhood of Gijon a large orange form occurs sparingly. In passing by rail from Leon to Corunna, small orange *Corbularias* were abundant between Leon and Astorga; and west of Astorga the large orange form similar to that at Gijon occurred sparingly at intervals.

Passing southwards, two forms, *C. nivalis*, with small orange flowers, the smallest known form, and *C. Graellsii*, with pale primrose-yellow flowers, occur abundantly on the Sierra Guadarrama at altitudes of from 3000 feet to 5000 feet; in a meadow near the Naval Peral Station they were growing in proximity, though not intermixed; *nivalis* occurred in a boggy part of the field, and *Graellsii* on the dryer ground at an elevation of about 4000 feet. Descending the southern side of the Sierra towards the Escorial, *C. Graellsii* bespangled like Primroses the moist pastures with tens of thousands of its pretty pale yellow flowers. I gather from Mr. A. W. Tait's "Notes on the Narcissi of Portugal" that the same kinds of variations occur in the Portuguese as in the Spanish forms of *Corbularia*. The following particulars are mainly derived from Mr. Tait's notes, and partly from my own observations. In several parts of Portugal the form *obesa* occurs: it is of low stature, orange in colour, and departs somewhat in shape from the other forms in the corona, being inflated or balloon-shaped, with a convex instead of a concave outline. I found this in the neighbourhood of Cintra in 1871. It grows at Coimbra, intermixed with the ordinary *C. Bulbocodium*, and on the Berlengas Islands, off the coast of Portugal, all the *Corbularias* are of the *obesa* type. Mr. Tait's enumeration of the Portuguese *Corbularias* is as follows:—

No. 1.—With short-stemmed, bright orange flowers, produced in February and March; found in the neighbourhood of Oporto, within 100 feet of the sea level.

No. 2.—With a much longer scape and larger flower than

No. 1, and an exceptionally large bulb, from hot marshes near the sea, at Ovar, twenty miles south of Oporto, flowering in March and April.

No. 3.—Somewhat similar to No. 2, but of the *obesa* type, from Cantanhede, forty miles south of Oporto, flowering about the 18th of April at an elevation of 30 feet above the sea level.

No. 4.—*Corbularia nivalis*, the smallest known form, was found abundantly by Mr. Tait at elevations ranging from 1500 feet to 4600 feet on hills near Povoia de Lanhoso and on the Gerez Mountains, flowering from the beginning of March to the middle of May, according to elevation, but much paler in colour, varying to white, than the form I found in the Spanish Sierra de Guadarrama.

No. 5.—A double variety of a form resembling No. 1, found at Ovar, flowering on the 17th of April.

No. 6.—One of Mr. Tait's most interesting discoveries is a supposed hybrid between *Corbularia nivalis* and *Narcissus triandrus*, flowering from the end of April to the middle of May, at an elevation of about 3500 feet on the Gerez Mountains. The corona resembled that of *Corbularia nivalis*, but the segments were broader, and reflexed like those of *Narcissus triandrus*. The seven specimens obtained in the years 1885 and 1886 were growing intermixed with the supposed parents. This, I believe, is the only known hybrid *Corbularia*.

And now, crossing to North Africa, two West European forms occur on the Barbary coast, opposite the narrow Straits of Gibraltar, viz., the typical *C. Bulbocodium* and the inflated form, *C. obesa*, in the neighbourhood of Tangier, but how far these extend east in the direction of Algiers has not been ascertained. In the province of Oran, as at Beniza, near Sidi-bel-Abbès, at Saida and Djbel Santo, and other localities, the nearly white *Corbularia monophylla* takes their place, and there is no record of the occurrence of any orange *Corbularia* in Algeria. *C. monophylla* appears to extend as far to the east as the longitude of Algiers, or a little further east than the eastern limit of *Corbularias* in Europe. It grows abundantly near the Cedar forest at Teniet-el-Ahd, and in the spring of 1873 I observed it in flower at Boghar, 70 miles south of Algiers, and again at Guelt-es-Stel, 150 miles south of Algiers; but the last is the most south-eastern point from which it has been recorded, and is probably nearly the south-eastern limit of the range of the genus.

It will be gathered from these records that, with the exception of *C. monophylla*, there is no definite line of demarcation between the various forms of the genus, which pass into each other by insensible gradations, and that even in their geographical distribution they are scattered through the region they occupy in a very irregular way, both as regards altitude and locality.

NOTES OF THE WEEK.

Primula Magenta Queen—We have received from Mr. E. S. Williams, Victoria Nursery, Holloway, flowers of this new form of Chinese Primrose. They are large, of good substance, beautifully fringed, and of a rich, clear, deep magenta; a strikingly effective Primula.

Christmas Roses—Mr. G. F. Wilson has brought us some remarkably fine blooms of Christmas Roses sent to him by Mr. W. B. Hartland, of Cork. The finest of the collection was Mr. Poe's variety with pink stigma, apple-green stems, and very large blooms. The flowers are well above the foliage and very erect. A similar flower was more imbricated, free from pink stigma, and the foliage stems more pale in colour.

Snowdrops and other early flowers—I send you a few of our giant Welsh Snowdrops; later on, when fully developed, they will be much larger. We have also in flower *Galanthus plicatus*, G. Shylocki, G. pœniformis, G. latifolius, and the double flowered form of our Big Welshman. How pretty *Erica melanthera* and *E. carnea* are at present! and so useful as cut flowers, when save a stray *Crocus*, a few Primroses, or a lot of white Arabis, our other flowers are few indeed.—J. A. WEBSTER, *Llondegan, Bangor*.

Scarlet Musa—A bit of glowing red is effectively furnished just now by *Musa coccinea*, at present beautifully in flower in the Trinity College Botanic Gardens, Dublin, from which Mr. Burbidge sends us a brilliant example. With it also came blooms of Cornish Yellow Daffodil. It is a strong and quick grower, increasing rapidly, and forces well. The flowers received were stated to be from a greenhouse.

Chrysanthemum Golden Gem—As a further proof of the lateness of Golden Gem *Chrysanthemum*, I send you a head of bloom. I find this to be the best of all late *Chrysanthemums*. Every flower-bud expands, and under the worst of treatment. Cuttings struck in April in small 3 inch pots and potted on

into 5 inch and 6-inch pots, and stopped three times, the last time being about the first week in July. That is all the treatment, so far as making it late, they have ever received—in fact, all my stock of *Chrysanthemums* is treated alike.—ROBT. OWEN, *Floral Nursery, Castle Hill, Maidenhead*.

* * The flowers sent are golden yellow, and marvels of freshness, being as bright and clean-looking as *Chrysanthemums* could be in the early days of November; the foliage, too, is equally fresh and healthy. This variety is evidently an acquisition.—Ed.

A gardener's orphanage—Mr. Penny, Sandringham, suggests that as a house for the orphans of gardeners is badly wanted, such an institution would be a suitable gardeners' recognition of the Jubilee year. Attached to the orphanage he proposes to have a piece of land for cultivation, a school to hold fifty boys and girls, or more as the funds may allow. If every gardener would contribute 5s. and every journeyman 2s. 6d. annually, he thinks that sufficient funds might be raised for the purpose here indicated.

Callicarpa macrophylla—The common *Callicarpa* (*C. purpurea*), with its long branches clustered with bright purple berries, is a well-known shrub. *C. macrophylla* is somewhat like it, but instead of the berries being purple, they are pure white. The two shrubs should be grown together, and one can imagine the pretty effect of the white and purple-berried stems intermixed. *C. macrophylla* is now in berry in the Palm house at Kew.

OLD HOUSE AND SURROUNDINGS.

WE lately received from Mr. Fowler Jones, of Quarrybank, Malton, a number of photographs representing beautiful woodland scenery and country seats taken by him, chiefly in the midland and northern counties. From these we have selected one for illustration in THE GARDEN. It represents a beautiful old house surrounded by a garden of quite an unconventional type, and is the property of Sir George Wombwell. The building shows one part of the original hall inhabited by the Colvil family, who lived there at the time of the Norman survey. Such specimens of pure old English architecture are now so rare, that peculiar interest attaches to them apart from the historical associations that are generally connected with them. The quiet colour of the weather-beaten and lichen-stained old walls is enhanced by the luxuriant tree and shrub growth that reaches almost to the doors and windows, and this is one of the chief differences between old and modern country mansions. Old houses almost invariably nestle peacefully midst unrestricted tree-growth; new ones, as a rule, stand on a treeless level, often amid a maze of pattern beds and gravel, and are rarely unaccompanied by a raised terrace, with its excessive array of statuary and other formalities. We fear that architects, not landscape gardeners, are often responsible for this state of things. They seem to have an abhorrence of greenery of any sort approaching their handiwork. The prevalent practice among architects now seems to be that of raising the floor line of their houses seldom less than 2 feet above the natural ground level; consequently the surrounding soil has to be made up to it at great expense, or you get the alternative of the conventional terrace, with a more or less steep bank having no connection with the outlying ground. It is, therefore, a great pleasure to come upon such a house as that here represented after visiting those of the modern stamp. One can picture to themselves the charms which the old garden in connection with such a house must present at every season of the year. It would be brilliant with flowers in spring, shady in summer, glowing with the rich hues of the decaying leafage in autumn, and sheltered and snug-looking in winter. W. G.

STOVE AND GREENHOUSE.

T. BAINES.

STATICES AND THEIR CULTURE.

THE distinct appearance of these plants, the enduring character of their flowers and the freedom with which they are, as a rule, produced, are properties sufficiently desirable, one would suppose, to have caused their being more generally grown for greenhouse and conservatory decoration than they have hitherto been. The different species and varieties of *Statice* that require greenhouse treatment are not open to the objection often—though groundlessly—urged against the hard-wooded section of greenhouse plants—that of being unsuitable for general cultivation on account of their requiring more attention in stopping and training in the early stages of their growth, and more tying when they get older than the commoner kinds. It would be difficult to point to any plants that need so little training as *Statices*, either whilst young or when they have

on growing slowly in the winter, and in this they are unlike plants that remain all but at rest during the dormant season. In common with most plants, they need plenty of light, but in the spring and summer they should have a slight shade in the middle of the day; in the absence of this their leaves, even where the growth is strong, do not attain the size they otherwise would do. When a little protection is given, not only does the foliage get much larger in size, but it is fresher in appearance, and the growth made is double that which is forthcoming when the full force of the sun is allowed to reach the plants. This is particularly the case with *S. profusa*, a seedling variety which, taking all its qualities into account, may be said to be the best of the *Statices*. The leaves of the different kinds, though somewhat soft in texture, are of an enduring character when the plants are kept free from insects, particularly aphides and red spider, both of which attack them, and which, from the partially drooping habit of the leaves, are often present in quantity on their under-side without being detected by

markable for the freedom with which they make roots, and which penetrate the soil within the pots, so that the whole becomes a mass of fibres. This points to the necessity for giving more pot-room during the early stages of growth than would be required by things that make slower progress in this direction. When free-rooting plants like these are not allowed sufficient room in their early stages, they suffer in a way that can rarely afterwards be remedied, as when the roots get so packed together in the soil the plants languish for want of sustenance, getting into such a stunted state, that nothing that can then be done in the way of additional pot room has the desired effect.

Statices are frequently grown in peat, but good, rich, fibrous loam suits them best, as, like most things that will succeed in either of these materials, the leaves have more solidity and endurance in them when loam is used than peat. In localities where good peat can be obtained, and the loam is of an inferior description, I should give the former the preference. But whichever

View of old house and surroundings. Engraved for THE GARDEN from a photograph sent by Mr. G. F. Jones, of Malton.

attained specimen size, as even when they are large, nothing in the form of support is necessary beyond a few sticks to keep the branches sufficiently open. The colour of the flowers of the different sorts of *Statice* is likewise the least common amongst greenhouse plants that are of an enduring nature, and this also may be set down in their favour. The texture of the flowers is such as to enable them to retain a fresh appearance on the plants for months, whilst their form makes them distinct from all others.

There are one or two peculiarities in the cultivation of *Statices* that must not be lost sight of; yet, taking them altogether, they may be set down as amongst the easiest things to grow, and with fair treatment such plants will last from a dozen to a score of years. I have had *S. profusa* at the end of fifteen years as full of health and vigour as ever. All the kinds will succeed under ordinary cool greenhouse temperature, but in the winter months they like to be kept a little warmer than many plants need to be, as to do justice to them they require to keep

those who have not had much experience in their cultivation. When these pests become at all numerous, they do much injury, not alone by the dull, unsightly colour which the affected foliage assumes, but the vigour of the plants is proportionately reduced through the premature decay of the leaves that are thus affected. But if during spring and summer a little forethought is used in keeping a look-out for insects, and when they are discovered means are at once taken for their destruction, they will give little trouble. Plants of most kinds that are grown under glass are especially subject to the attacks of insects; and the want of exercising vigilance in their detection and destruction is the rock on which the expectations of not a few who attempt plant growing are wrecked.

Where attention is given to the matters above-mentioned, no one need feel doubtful of succeeding with these plants, which, as I have already intimated, will well repay the little care required to keep them in a thriving condition. When the foliage is clean and healthy, the plants are re-

is used, it should be of a nature that will admit of its lasting, as there must be no attempt at shaking out with the intention of renewing the material in after years. An addition of leaf-mould is sometimes advised for *Statices*, yet, though it gives an impetus to the growth for a time, it is better not to use it for these and other plants that do not like being periodically, all or partially, shaken out, as the material in question is deficient in the enduring properties that should be present in soil that the roots have permanently to remain in.

Those who prefer propagating the plants themselves will find no difficulty in striking cuttings. These should consist of shoots taken off in spring, severing them at a point where the wood is in a half solidified state. Some of the lower leaves will require removing, being careful in doing this not to injure or strip off the bark. The cuttings should be put singly into small pots partly filled with a mixture consisting of equal parts of sand and finely sifted loam, with sand alone on the top. Keep them moderately

moist and confined under a propagating glass, shading from the sun. They will not root so quickly as some things; consequently an intermediate heat will be safer for them than the high temperature that answers for plants that root quickly. After sufficient roots are present disperse with the glass, but keep the little plants on in a growing temperature through the summer, with shade in bright weather. They will require moving into larger pots before the season is too far advanced to admit of the roots getting well established in the soil. A temperature of 45° will suit them during winter, standing them where they will have plenty of light. So treated, they will keep on moving slowly. In spring cut out the points of the shoots. It is necessary to attend to this in good time, as if left to themselves the plants will not branch out low enough, the growth simply being confined to a single shoot until they are too tall and leggy. Plants of this character of any of these *Staticee* must be avoided, as they will never make well-furnished specimens; 6-inch pots will now be about the right shift to give them; this they should have early in spring. In the matters of air, light, and water, treatment such as is required by the generality of young hard-wooded greenhouse plants will answer, keeping a little more moisture in the atmosphere than is necessary for older stock, shading as before advised when the weather is bright and syringing freely when the house is closed in the afternoons until the end of summer, when more air and a drier condition of the atmosphere will be an advantage. All that will be needful this season in the way of stopping is to pinch out the flower shoots as they appear. So naturally inclined are most of the kinds to bloom, that they will produce flowers when the plants are quite small, yet it is much better not to allow them to do so until more size has been attained, as blooming at this stage will interfere with growth. Little, if any, shoot-stopping will now be necessary, as one peculiarity common to the different kinds of *Staticee* is that each flower-stem that appears divides at the extremity of the shoot from which it springs so as to form a second shoot, and in this way the plants continue to multiply their branches so long as they exist. As the branches get long enough to admit of their being tied out they should be secured with a few neat sticks and ties in a horizontal position, by which means the base of the specimens will be furnished, and overcrowding of the shoots in the centre of the plants will be avoided. After the second summer they may be allowed to bloom; some of the sorts, *S. profusa* in particular, will keep on pushing up flower-stems from early in spring to the end of summer, and these will open in succession, keeping the plants gay for half the year. After this larger shifts will be required at the annual potting, which, with these plants, is always best carried out early in spring. With a continuance of the treatment recommended they will attain a large size, ultimately needing pots 18 inches in diameter, or even larger, but when the specimens are in pots approaching these dimensions they must not be potted oftener than once in two years, assisting them during the growing season with manure water. *Staticee* are not so liable to die off suddenly in the way that some things do. I have had plants which, at the end of fourteen or fifteen years, were as vigorous and free in growth as when they were not more than as many months old. The best sort, *S. profusa*, is a small-leaved, bushy-habited kind, a good grower, and a free bloomer. *S. Butcheri* is a very fine variety, a strong, rapid grower; the flowers are produced freely, and are a fine deep shade of blue. *S. Holfordii* also is a strong, free-growing sort, with stout, many-branched flower-stems,

S. imbricata is a desirable kind that grows and flowers freely.

Asters in spring.—At a meeting of the French National Horticultural Society in April last some well-grown plants of *Asters* were exhibited in good bloom. It is not stated what particular variety they were, but they varied in colour, and it is certainly interesting to know that double *Asters* can be had in full flower in the spring months. The seeds were said to have been sown in summer, so that the plants just had time to make their growth. One would think that well-flowered pots of *Asters* would find a ready sale in Covent Garden in spring. It appears to be an easy matter to get them at that time of year.—BY FLEET.

Echeveria retusa.—This charming succulent blooms very freely, and is distinct in character from the general routine of winter-flowering plants. It is very compact in habit, bears beautiful red and yellow flowers, and may be easily propagated by means of the little off-shoots that are annually thrown up from the old stools. Great care must, however, be taken when the cuttings are put in that they are not over-watered, as being soft and fleshy they are very liable to damp off. A good plan is to lay them on a shelf for a few days to dry. They will do well if, after being established in pots, they are placed in a cool frame during the summer months, and in early autumn transferred to a moderately warm greenhouse.—T.

Roman Hyacinths.—The demand for white flowers at all seasons makes these *Hyacinths* doubly valuable, and the length of time during which they may be had in bloom is not the least of their recommendations. Other *Hyacinths* may be larger, but their size militates against their usefulness in a cut state. We do not force *Roman Hyacinths* into bloom nearly so early as might be done, because during autumn there is such a wealth of other white flowers, that they are really not wanted. Between December and April, however, they are most valuable, and, by having a succession of boxes in cool houses, and bringing them into gentle heat to open their flowers fully, a supply may be kept up, as they remain long in a half-open state in a cold house. Having quantities of bulbs that had been used in pots and boxes for one year, I have at various times planted them out, close to the foot of walls in various aspects, and they become useful for a late supply. The only attention they require is to put a little litter over them if very sharp frost sets in after they push through the soil, which they do before the ordinary Dutch kinds. Close to a wall, however, with a few glass lights or thatched hurdles put over them at night or during rough weather, they expand, fresh, fair, and fragrant, and, without any expensive appliances or scorching fire-heat, this lovely flower may be had nearly half the year.—J. GROOM.

Chinese Primroses.—Whilst a visit to Woodside, Farnham Royal, in a couple of months hence will be rewarded by the sight of some 2500 plants of Mr. James's best strain of *Cinerarias* in bloom, even now a visit is amply repaid in seeing the several hundreds of *Chinese Primroses* there which, in the clear light of that elevated rural district, exhibit the purest colours and the finest of culture. Better plants cannot be seen anywhere. All are sturdy, clean, and healthily luxuriant, both in foliage and in bloom. The old Market White, which always produces tinted flowers, is nevertheless a grand strain, the flowers of which are of wonderful size and substance, and make fine heads of bloom; constant selection has done this. The finest pure white is a light, Fern-leaved kind, that produces very large ivory-white flowers, borne in big trusses on stout stems, and presents one of the most perfect white *Primulas* yet seen. Another of great beauty has pure white flowers on reddish foliage; and yet another has mauve flushed flowers on dark red foliage. The lavender or marginate strain is wonderfully fine, and the flowers if anything over-large. The single red and single blue are of the best of their kinds, and a very pleasing form has reddish cerise flowers. The only semi-

double is one producing fine flowers of a magenta-red hue; this is a grand strain. All the plants are in perfect health, and when seen in masses of colours and sorts, command almost enthusiastic admiration, they are so exceedingly beautiful.—A. D.

STEPHANOTIS FLORIBUNDA FAILING.

It would be difficult to name a more popular plant than this, but although so well known, it is by no means generally to be seen in a flourishing or profitable condition. The reasons for this in some instances are not far to seek. No plant is more liable to be infested with mealy bug, or, during the period of active growth, more difficult to clean. A few years ago it was considered the best plan to take down the whole of a dirty plant and perhaps dip it in some bug-destroying solution, afterwards returning to the roof or trellis, as the case may be, only to find that the dose must be repeated several times before the bug is eradicated. I have frequently seen large plants of *Stephanotis* gradually taken down, the joints scrubbed with brushes, and the leaves sponged, some kind of insecticide being used at the time. The result of such a proceeding is a much-scratched and otherwise badly damaged plant, but no real clearance of the bug. The remedies are perseverance and petroleum, both being cheap, and altogether superior to the many nostrums, none of which, however, that I have tried, being really effective. There is no necessity to loosen the plants from the wires. After they have been duly pruned and thinned, and before active growth commences, the insect pests should be destroyed. Our remedy is two ounces or a wineglassful of petroleum (more commonly termed paraffin) to a gallon of soft water heated to about 120°. Some add a lump of soft soap about the size of an egg to every 3 gallons of water, but we have tried this repeatedly without discovering any advantage in its use. If two syringes are available, one is kept constantly forcibly discharged back into the can, and the other syringing the infested plants. When one syringe only is employed, every second discharge should be back into the can, as it is only by these means that the oil can be kept from floating on the surface. Merely damping the plant with the petroleum and water is not sufficient. It should be well driven into the clusters of bug, thus causing their rapid destruction. This must be persevered with, no one application being really effective, and if the later syringings have to be given during bright, sunny weather, a heavy shading overhead is necessary, otherwise the oil may cause the loss of a good many leaves. In hot weather it is also advisable to syringe with clear water soon after the oil has been used. Petroleum thus applied injures neither the foliage nor roots, and destroys scale as well as bug.

METHOD OF PRUNING.—This is sometimes answerable for a comparative failure of the *Stephanotis*. In many instances we see plenty of strong, healthy growth and few or no trusses of bloom. Very frequently the blame for this is attached to the variety, many holding, and it may be with some good ground, that there are forms in existence which flower anything but abundantly. Such was my conclusion at one time, but I have since considerably modified my opinion. We are supposed to have one of the best forms, and have raised plants for friends who covet them. Some of these flowered most satisfactorily and others quite the reverse. According to my experience, plenty of bloom in long succession, or say from the spring till the autumn, is best obtained by affording a limited root-run, a light position for the growths, a good rest in the winter, as well as a cautious use of the knife. One of the most floriferous plants I have yet seen, and which covered the roof of a small span-roofed stove, was growing undisturbed for three years in a 12 inch pot. It is almost needless to add that it was very carefully attended to, being watered during hot weather two or three times daily, a good top-dressing of old cow manure being given each spring, and frequent weak supplies of guano water

when in active growth. A careless cultivator would fail with a large plant in a comparatively small pot, and those who cannot attend closely to the wants of a large specimen will do well to plant it out in a loose brick pit situated somewhere near the pipes. Such a pit might be about 3 feet square and 2 feet in depth. A suitable compost would consist of two parts of turfy loam to one of good fibrous peat, both roughly broken up, and to this may be added a sprinkling of charcoal, mortar rubbish, and decayed manure, silver sand also being plentifully used. When the plants are breaking afresh is the time to turn them out of pots, and if the roots are carefully loosened from the old mass of soil, much of the latter being picked away, and well spread out in the new soil, they will soon take to their fresh quarters. In succeeding years it may be advisable to occasionally renew the soil in these pits. This, owing to the walls being formed with loose bricks, is a simple matter. The top-dressing given may consist of old cow manure, or, failing this, some fresh compost and a little bone meal may be added. While growing strongly abundance of water should be given, and those that are flowering freely also require frequent supplies of soot water, or some kind of artificial manure, always, however, in moderate quantities. Such treatment usually induces a healthy growth, and at the end of the season the plant will be well furnished with plenty of long and fairly strong growths. From September to the end of the year little or no bloom will open, and it is during that time that they ought to be rested. Only sufficient water should be given to keep the foliage from flagging and the roots from perishing, and this, coupled with a fairly dry atmosphere, ensures the ripening of the wood. Plenty succeed very well up to this point, but after well maturing these long growths they proceed in January or early in February to cut them hard back to near where they started from. The consequence is a vigorous break, and little or no bloom for some time or till the leading shoots are several feet in length. The proper course is to leave the greater portion of these well matured growths their full length, only cutting away any that may be weakly, or thinning out where they are at all crowded. Near the ends of many of these reserved growths there are frequently several embryo trusses formed late in the season, which increased heat, moisture, and sunshine quickly develop. This is a distinct gain, but compared with more important results following is trifling. Well matured growths will break at nearly every joint, and these young shoots are usually short-jointed as well as extremely floriferous, soon becoming literally clothed with fine trusses of flowers.

THE BEST POSITION for a *Stephanotis* is on wires fastened about 6 inches from the roof of an ordinary plant stove. Instead of training the growths in all directions, aiming only to cover the roof in any fashion, it will be found a far better practice to dispose the wires across the roof about 10 inches apart. Two or more growths may be trained along each wire, and the flowering shoots allowed to hang loose till such time as they become long or unsightly. Trained in this manner, the *Stephanotis* does not unduly shade any plants that are grown underneath, and may also be more easily kept clean. Frequent syringings serve to keep them clean, and are otherwise beneficial. They will stand any amount of heat, and, if healthy, plenty of sunshine also, but we shade lightly with blinds during the hottest part of the day—this in preference to any kind of fixed shading. Fine specimen plants seen at various flower shows are apt to mislead beginners. They are not supposed to know that these attractive specimens are not constantly trained over the formal balloon-shaped trellises on which they are flowering. Any novice, however, who attempts to both grow and flower their plant on a balloon trellis is liable to fail. During the greater part of the year all the leading growths should be thinly trained near the glass. A short time before they are wanted for exhibition they may be carefully

taken down and trained to the best advantage. We sometimes see the *Stephanotis* recommended for cultivation in conservatories, but in every case where I have known it tried, failure was the inevitable result. Conservatories, as a rule, are too heavily built, or else too cold to suit what I consider to be properly a stove plant. Even if the house is kept warm enough to induce free growth this rarely matures satisfactorily, and a flowerless *Stephanotis* is quite unattractive. Strong, well-ripened pot plants, or any which may be tubbed, will flower abundantly in a fairly warm greenhouse during the first season after removal from the stove; but I have observed that there is a great falling off indeed in the second, and failure eventually results. When at rest no harm will follow occasional low temperatures, but I would not winter a *Stephanotis* in a greenhouse. During the resting period the night temperature may safely range from 55° to 60°, and in the daytime 5° to 10° higher, but after active growth commences we like the temperatures to be respectively 60° to 65° and 65° to 75°, an occasional variation either way not much affecting the well-being of the occupants of the house. W. I.

ABUTILONS.

THESE NOW popular South American plants are very useful during the dull winter months, and also in early spring, as they yield their flowers in such close succession that one can always gather some from them. If kept in a moderate temperature they will keep on growing and flowering all the season. They are very easily raised from seed, which ripens well in the south of England. Some very beautiful varieties have been raised in this country, especially by Mr. George, of Putney, who some years ago made the raising of new varieties of *Abutilon* a special study. On the Continent, too, a double form has now been secured. It was raised from the now well known *A. Thompsoni*, and is its exact counterpart, except the flowers, which are decidedly double, but of really no beauty. *Abutilons* may be propagated easily from cuttings of the young wood, which strike freely in a bottom-heat of between 50° and 60°. Grown as pot plants, they are both useful and ornamental for the decoration of the conservatory. There may now be seen in the gardens of the Royal Horticultural Society in small pots a number of plants quite covered with beautiful flowers. As plants for pillars, too, *Abutilons* cannot be too highly recommended. When planted out in the greenhouse against a pillar, it is necessary to prepare soil for their reception. They thrive best in yellow loam, with an admixture of sand and rotten manure from an old Mushroom bed. *Abutilons* are gross feeders, and manure water may be administered to them with beneficial results. They may also be used with advantage in the sub-tropical garden, and none more so than the variegated form *niveum marmoratum*, which when pegged down makes a pretty edging to such plants as *Cannas*, *Solanum marginatum*, *Ricinus*, *Aralias*, &c. *Abutilons* also do well planted out during the summer months, more especially *Boule de Neige*, which during the season will produce its snow-white flowers in great abundance. In autumn on the appearance of frost those planted out may be lifted and potted in any ordinary soil, and kept in a warm house till they have become established; they may then be transferred to cooler quarters, and during the winter months kept rather drier. If cut down and put into heat in early spring they will yield cuttings in great profusion. All the varieties, with the exception of *insigne*, known now by the name of *igneum*, and *Sellowianum marmoratum*, are amenable to the greenhouse and summer treatment just described. The two last named varieties, however, require stove management.

The following is a list of varieties found to be the best, viz. :—

WHEELS.—*Boule de Neige*—Branching in habit and a very free flowerer; blooms of medium size, finely cupped, pure white. If the stamens are removed, the flowers of this sort

are very useful for any purpose for which white flowers are required. *Seraph*—Dwarf in habit, flowers white, more elongated than those of *Boule de Neige*.

LILACS.—*Anna Crozy*—Vigorous in habit, and a free flowerer late in the season; blooms large, with dark veenings; very pretty. *Louis Marignac*—Dwarf and compact in habit, free flowerer, and very showy.

YELLOWS.—*Lemoinei*. The counterpart of *Boule de Neige*, except in colour. *Reine d'Or*—Dwarf and compact in habit, flowers large, and of a beautiful bright yellow.

ROSE.—*Rosaeflorum*—Dwarf and compact in habit, a very free flowerer; the best of its colour. *Darwin robustum*—Strong in growth, rose, with a slight shade of red. *La Lorraine*—A very fine free-flowering variety.

PURPLE.—*Insigne* (syn. *igneum*) A tall grower; leaves large and rough; flowers, produced in clusters, of a medium size, broad, much reflexed, purple-crimson, with dark veins; a very useful and distinct variety, and one which ought to be in every collection. Figured in THE GARDEN, Vol. XVIII., p. 324.

VARIEGATED.—*Niveum imbricatum*—Leaves large, marbled pale green and yellow; valuable as a fine foliaged plant, and for bedding purposes. *Darwin tessellatum*—A beautifully variegated form, the leaves of which are prettily marbled with gold and yellow; flowers reddish, with distinct crimson veins; beautiful either in or out of flower. *Sellowianum marmoratum*—This, the handsomest of all the variegated section, requires stove treatment in order to develop its beautifully marbled foliage.

W. P. T.

Acacia longifolia.—With respect to the note on this excellent *Acacia* in THE GARDEN (p. 91), allow me to observe that there are two varieties of it—at least, there were some years ago, not differing perceptibly in growth and foliage, but remarkably so in floriferousness. I have known the shy-flowering variety to be grown for years without yielding a bloom. It may be that this has gone quite out of cultivation; if so, all the better, as it is a worthless thing; but if some of your readers have been unsuccessful in blooming this *Acacia*, they may conclude that they have the wrong kind, and may at once consign it to the rubbish-heap. The free-flowering variety is sure, under ordinarily good culture, to bloom well. —BYFLEET.

Brugmansia Waymanniana.—Mr. Gumbleton kindly sent me vol. iv. of Paxton's *Magazine of Botany*, and I see by it that my double *Brugmansia* is not *B. Waymanniana*, or at all like it. *B. Waymanniana* bears the same relation to a double one that a *Hose-in-hose* bears to a double *Polygonus*; that is to say, it is not double at all. Nevertheless, the peculiarity of shape and colour renders it a highly desirable plant. Paxton says that it was raised in a private garden from seed sent home from South America. It ought not to be beyond the powers of some of our enterprising nurserymen who have trade connections with that part of the world to re-introduce such a desirable plant if, as I suppose is the case, it has been lost to cultivation. Of course, if the plant that was raised in England was a chance sport and not typical, it is very unlikely that we shall ever look on it again.—FREDERICK TYMONS.

Gladiolus brenchleyensis in pots.—This is the brightest coloured of all the *Gladioli*, and it is the only one amongst the large-flowered section that blooms well in pots. Anyone who requires a quantity of bright flowers, either in pots or in a cut state, all through August cannot choose an easier subject to grow than this *Gladiolus*, or one that will prove more effective. The colour of the flowers is a fiery-red, and strong roots give such a grand spike of bloom, that for effectiveness there is nothing available for so many purposes to surpass them. If required, the bulbs can be potted in the sized pots that will be most suitable for particular purposes: but in general it is best to place six roots in an 8 inch pot, as the more soil the roots have the stronger will be the flower-spike. If there is no particular time at which they will be wanted in flower, they are best brought on in a cold frame; but it is a simple matter to retard them in June if needful to do so.—J. C. C.

SHORT NOTE.—STOVE AND GREENHOUSE.

Asparagus plumosus nanus. This graceful plant, which has hitherto, for the most part, been grown for the ornamentation of plant stoves or that of dinner tables, bids fair to supplant even the *Maendhair Fern* itself for such purposes. Its sprays when cut are also admirably adapted

for mixing, with cut flowers, in bouquets, and in the numberless other ways in which elegant greenery can be employed. This dwarf variety is largely and well grown by Mr. Luing at Forest Hill.

SEASONABLE WORK IN PLANT HOUSES.

STOVE.—The length of time during which a large well-grown specimen of *Stephanotis* will continue in bloom is such that where two or three plants are available, there is no difficulty in having a succession of its highly perfumed flowers during much of the spring and summer. The plant, even when required to cover a large space, does not need nearly so much root room as many things, or as is often given it. In common with most free-growing climbers, it thrives the fastest when planted out, but large specimens will continue for a number of years in a healthy condition when their roots have no more space than an 18-inch or 20-inch pot affords. And when thus grown there is the important advantage of being able to regulate the time of blooming by moving the plants to a warmer, or a cooler, structure at will; whereas when they are planted out in a bed their time of flowering is wholly dependent on the temperature that is kept up in the house where so located. Pot specimens that have been wintered in a temperature of about 55° should be moved to warmer quarters; 65° in the night will not be too hot for them. The roots will have been kept in a somewhat dry condition during the time the plants have been at rest, but the soil must now be well moistened. With the heat named, growth will commence at once, and if the last year's wood has been well ripened the young shoots will not extend far before they show flower from every joint. Except in the case of young examples that are required to be grown on, potting should not be attempted until after the plants have flowered.

COMBRETUM PURPUREUM.—Although much less useful for the production of cut flowers than some other stove plants, this is a fine plant for clothing a pillar or rafter, or for training over a path in the stove. Young plants that are required to fill more space should have enough root-room to support top growth, and unless the soil is not fully occupied by the roots, larger pots ought to be given now when the growth is beginning to move. In the case of full sized specimens some of the surface soil may be removed, replacing it with new; at the same time look to the drainage to see that it is in a condition that will enable the water to pass freely off. Being a slower grower, and also more limited in the extent of growth that it makes than many stove climbers, this *Combretum* requires proportionately smaller pots than the more vigorous occupants of the stove.

SARRACENIAS.—To grow these plants well there are several matters connected with their cultivation that need to be carried out to the letter, and without which their singular leaves will never attain anything like the size which they are capable of. The first essential is that the whole of the old material in which they are grown must be shaken away and replaced with new once a year. If this is not done, from the saturated condition it requires to be kept in, it is liable to get more or less too far decomposed for the roots to keep healthy in it. It is of equal importance that the shaking out and repotting is carried out before the roots have begun to move, otherwise the tender points of the young fibres are sure to get a check, the result of which is that the leaf growth that follows will be weakened. When the plants are wintered in a night temperature of about 48° or 50°, with a rise by day proportionate to the weather—which is better for all the species and varieties than if kept warmer—all the sorts except the different varieties of *S. Drummondii* will be in a condition to repot at once. The *Drummondii* varieties must be repotted in July, at which time their roots are usually quite at rest. The fibrous matter out of good Orchid peat with chopped Sphagnum, broken crocks, and a little sand, is the best material to grow them in. Give a good soaking with water as soon as the potting is com-

pleted. Stand them with their tops close to the glass in a light house, with no more shade than a thin piece of canvas over them whilst the sun is bright. Give an intermediate heat during spring and summer, with plenty of water once a day. Neither thrips nor greenfly must be allowed to have a lodgment on them, or the leaves will be disfigured. Treated in this way anyone may grow these interesting plants, the flowers of which are even more curious than the leaves, although it is better to pinch them out as soon as they appear until the plants get strong, as, in common with most things, blooming weakens *Sarracenas*.

DIPLODENIAS.—Where these plants were re-potted in the autumn, which time is the best where a warm stove temperature is maintained during the winter, they will now be in active growth. Regular attention will be needful to keep their twining shoots from getting entangled together. To do any good with these plants, the young shoots as they grow must be trained to wires or thin strings so placed that the extremities of the shoots as they extend are a little on the ascent. If allowed to hang down they will come weak and make little progress. Care must be taken not to over-water, as any excess of moisture in the soil is fatal to the roots. The white-flowered *D. belviensis* is the most useful of all for cutting, though the flowers individually are less conspicuous than those of the others. It does better planted out than the other kinds, either species or hybrids, do. So treated it will cover as much space under a roof as a *Stephanotis*; it will also succeed with less heat than the others. In stoves where the winter temperature is comparatively low, *Dipladenias* will now only be commencing to grow, in which case where the plants have attained full size they may be turned out of the pots, and the old soil shaken away, not disturbing the roots more than can be avoided, repotting in new material; good, turfy peat that is full of vegetable fibre, with a liberal addition of sand and some dry manure, such as is obtainable from an old Mushroom bed, is the best to grow them in.

IMPATIENS.—The merits of the ever-flowering *I. Sultani* are now so well known, that nothing requires to be said in its favour. Not the least of its valuable properties for ornamental purposes is that it will flower in even the smallest state. *I. Hawkeri* promises to be even better than the earlier introduced kind, the colour being more intense. Cuttings of these pretty Balsams should be put in; they will strike readily in a brisk heat. Young stock now propagated will begin to flower almost as soon as they get established in small pots, and will continue blooming as long in autumn as there is enough heat kept up to enable them to make growth. But, like other quick-growing plants that are soft in the texture of their shoots and leaves, if not stood close to the glass, they soon get so much drawn and puny as to have an indifferent appearance.

GREENHOUSE CLIMBERS.—Most of the kinds of climbing plants that are used for covering back walls, training round pillars, or draping the rafters require more or less cutting in once a year; but, in carrying out this work, it is necessary to take into account the more or less vigorous habit of the plants, shortening the branches proportionately according to the extent of top growth each particular species makes; and it is equally necessary that the time of pruning should be varied; species that flower from the current season's growth should be pruned at the present time before the plants begin to push their shoots. On the other hand, the various kinds that flower in spring from the growth made last summer must have whatever pruning they need deferred until after they have bloomed. In the case of such as are planted out in beds or borders, they should have assistance by top-dressing with new soil sufficiently enriched by the addition of manure. To make way for this, as much of the old exhausted material from the surface of the bed as can be got away without disturbing the roots should be removed. Inside borders wherein plants of the description under notice are grown are usually shallow, with drainage

material underneath, and, with the limited supply of water that is applied during the season of rest, it not unfrequently happens that the mass of soil gets so dry that it takes more water to moisten it through than is supposed, though the surface may appear wet enough. In such a condition it is scarcely necessary to say that healthy root growth is out of the question, the result being that the shoots come weak and the foliage gets infested with insects, which invariably seem to revel on plants that are wanting in healthy vigour. To avoid this, all beds and borders should now be examined to see that the soil is fairly moist all through. Roof climbers, if allowed to get infested with insects, naturally communicate them to everything that is grown underneath them; to prevent this, the whole should be gone over, giving them a thorough cleaning.

PLANTING CLIMBERS.—The present time, and a little later on, according to the earlier or later period of their growth commencing, is the best season for planting out greenhouse climbers. Success with plants of this character that are expected to go on for a number of years in a great measure depends on the preparation that is made for them. The soil, whether peat or loam, should be the best of its kind that can be obtained, containing enough vegetable fibre to enable it to keep in a sweet, healthy condition until the roots have had time to get well hold of the whole mass. In addition to this, sufficient sand, with broken crocks, crushed sandstone, or charcoal to keep it porous, should be added, and in all cases enough drainage ought to be placed in the bottom, with means for the water that percolates through the bed to pass off.

T. B.

FLOWER GARDEN.

CULTURE OF GLADIOLI.

A FRIEND writing to me the other day says, I do not think that there is any flower about whose culture there is so much difference of opinion as about the *Gladiolus*; and the columns of THE GARDEN fully bear this out. One week there appeared an article in which it was stated that there was no necessity to wait until the foliage had decayed before lifting the bulbs; while another writer stated that we should have to send the bulbs to Jamaica in order to get them thoroughly ripened. The same difference of opinion has been manifested in the matter of soils; some have contended that they ought to be grown in light soil; others, like myself and Mr. Burrell, of Cambridge, have maintained that heavy soil suits them best. Now, on both these points I wish to offer a bit of evidence. I have had lately the opportunity of seeing a number of the bulbs lifted by Mr. Burrell, and I say it advisedly, that after more than thirty years' knowledge of *Gladiolus* growing, and after having seen the bulbs of most growers both in France and this country, that they were a perfect revelation to me, for I have never seen such bulbs, so far as size is concerned, while in healthiness and freedom from any symptoms of disease, they could not be surpassed. Many of these bulbs measured 10 inches and 11 inches round, and that not merely such kinds as Shakespeare, which always is large, but other varieties, of which we have been contented to have small-sized bulbs, such as Baroness Burdett Coutts, Dalila, Mabel, &c., were of the same size; then they had that silvery appearance in the skin which always characterises the French sorts. Now there are other points connected with the culture of these roots: 1st, they were grown on stiff soil, of course well cultivated and drained; 2nd, they were not lifted until the first week in December; and 3rd, quite 80 per cent. of them had been produced from bulbs which had been cut in two before planting. The second point in this is to me a novelty. I have myself never deferred lifting my bulbs so late, but after what I have seen of these Cambridge bulbs, I shall most certainly defer the lifting of my small stock to a later period. It may be asked, Is there any ad-

vantage in having such large bulbs? Yes, unquestionably, if they are well ripened, more especially for northern and late districts, for these large bulbs always bloom earlier than the smaller ones; then you can cut them in halves, thus doubling your stock. Of course, if the bulbs are not well ripened, there is great danger in these large ones losing vigour, but with such ripened bulbs as these there can be no risk of that.

These bulbs, too, seem effectually to do away with the action of degeneration, so that when properly grown and in suitable soil, our English grown bulbs are superior to the French. Many of these bulbs are from some which were imported from France three years ago, and although the old bulbs decay every year, we may, in ordinary language, call them three-year-old English-grown bulbs, and I do not think, therefore, that it can be pretended that the losses which many of us suffer is to be attributed to degeneracy. Mr. Burrell suffers, so he tells me, very little from the disease to which they are subject, soil and climate both appearing to agree with them.

In looking through my own stock of bulbs, I find that they are keeping well. I have never found that bulbs which are healthy when lifted go off afterwards before planting time, while those which were unsound at that period become gradually worse, becoming black and shrivelled, and without any signs of life in them; but, strangely enough, when a diseased bulb is potted after lifting time, I find that it frequently throws up a shoot from what seemed only a mass of decay.

DELTA.

Tropæolum tuberosum.—Some complain that this is a shy flowerer; but with us it is annually a sheet of bloom during the greater part of the summer. A few years ago I put a few roots of it against a wall, and they grew so fast that they quickly covered the space allotted to them, and took possession of a Rose tree on the same wall. In short, they flowered and grew to such an extent, that they had to be constantly cut away to keep them within bounds. In another case a plant of this Tropæolum took possession of an Arbor-vitæ hedge 6 feet high, and literally covered it with growth long before the summer was over and flowered freely. In this district many plant it against their houses and form bowers with it, and no creeper is more effective. I find that a rich soil is not of so much importance as one of a lighter and more porous character. It is especially partial to lime rubble, and does not object to take to a gravel walk, which shows that warmth for the roots is as essential as good soil; being quite hardy, it may be planted at any time before it starts into growth.—J. C. C.

Paneratiums out of doors.—*P. maritimum* and *illyricum* do well in the open air in summer in some of the southern counties; but even under the best of climates they require a warm border and a rather dry soil. They are, however, so delightfully fragrant, that they are worth an effort if they can be induced to thrive. I find that when cultivated in the open, the flower-stem is stronger than in pots; consequently the heads of flowers are larger. Many might grow these Paneratiums in pots, and keep them under glass; where they have failed, it has been through giving them an insufficient quantity of soil to support vigorous growth. When thoroughly healthy, and surrounding conditions are favourable, they make a number of leaves and roots in proportion, which cannot be sustained if confined to small pots. There should now be no delay in getting the bulbs potted, and, as the strongest are rather large, each one should have a pot 7 inches in diameter. As regards compost, equal parts loam and leaf soil and a sprinkle of sand suit them admirably.—SOMERSET.

French Anemones.—These may be planted now, but in favourable situations it is best to plant them in November. Put in now, however, they will flower late in spring. The double varieties are grand flowers for a bed or for clumps in choice positions; the colours are so various and bright, that each individual blossom accompanied by two or three of its own leaves is a host in itself. The single varieties produce the greatest number of flowers, and, if possible, the colours are more diverse; but both are so beautiful and so easily grown, that there is no need to praise one at the expense of the other. What further enhances their value is the fact that, if required in a cut state, and they are taken just as they are about half expanded and placed in water, they will develop blossoms as well as if left on

the plant, and remain in good condition for a considerable time. As regards cultural details, it is necessary that they have the full benefit of the sun, and that the soil be rather light and friable, and kept well watered in dry weather. They are not averse to a heavier root medium, provided it is well drained and broken up into small particles before planting.—J. C. C.

New Violet.—The Messrs. Forgeot, of Paris, are distributing a Violet of their raising which promises to be a useful addition to kinds now in cultivation. It unites beauty of foliage with great precocity and continuity of bloom. The leaves are so distinctly marked with golden stripes as to render this Violet extremely ornamental when used as an edging. It commences to bloom in October, and sometimes as early as September. It is of seedling origin, and has retained its distinctive character over a period of more than seven years. It is called *Marie Guerin*.—J. CONSHILL.

CLEMATIS DAVIDIANA.

THIS useful Clematis is not cultivated as much as it deserves to be. Its large, deep green, Vine-like leaves and clusters of pale blue flowers, of a very rare and delicate quality of colour, entitle it to a place in the choicest collections. Probably it is only hardy in our southern counties,

Clematis Davidiana. Engraved for THE GARDEN from a photograph.

and even there likes a warm sheltered place and a little dry Fern for winter protection; but its distinct character and refined beauty well repay a little care and trouble. It forms a bushy plant about 2 feet high and flowers in July.

Primroses in the sunlight.—We are compelled to grow all our Primroses and Polyanthuses here in the full light of the sun, having no shade. Double Primroses will not stand it, but singles thrive admirably. The soil is very stiff and has a clay base, but none the less burns and bakes exceedingly under hot sunshine. The worst enemies of the plants are found in thrips in the summer, and excessive wet in the winter. Old plants are rarely worth retention after three seasons' blooming, although some will divide fairly well. Still, it is obvious that divided plants never seem to have that robustness which is found in seedlings. In raising a big batch of seedlings every year we are independent of old plants, and do not care to preserve them beyond the third year. I have often noted that even wild Primroses growing in shade and in cool, deep-soiled woods rarely show plants of great age; indeed, apparently seldom

beyond three years old. The inference seems to be that Nature reproduces by seed annually, and that old plants soon die out. I find the snow and frost have not appreciably injured Primroses or Polyanthuses, and where in frames the autumn-raised seedlings had become loosened somewhat, a heavy watering has rendered them firm. Because of the tendency of the soil to harden so much under the influence of heavy winter rains, I have of late refrained from planting the seedlings out in the early winter, but keep them in frames where they get strong, and go out admirably in fresh-dug soil in the spring. I have several thousands of Primroses and Polyanthuses thus to go out now, and I am assured that the plan is the best for still soil, and induces to after-endurance and robustness.—A. D.

DOT PLANTS IN FLOWER BEDS.

OF the newer departures in summer bedding none have a more pleasing effect, or are likely to last longer in public favour, than the employment of what are generally known as dot plants in a carpet either of flower or foliage, and as the season for thinking about the summer arrangement of the flower garden is approaching, let me put on record a few combinations which may be new to some of your readers. The system finds favour from its diversity of outline, and from the way in which it relieves all flat uniform surfaces, whether carpet beds, pure and simple, or blocks and masses of colour. Tuberous Begonias are very useful for this work, and have a more pleasing effect when thus employed than in masses. The large flowering varieties are admirably adapted for dot plants, and where named sorts are not at

hand, good seedlings of decided colours in scarlet, pink, and light shades should be selected, care being taken that they are free-flowering and of sturdy robust habit. The best carpet for scarlet Begonias is the *Mesembryanthemum*; a few dotted here and there in this groundwork, and far enough apart to show up the variegated foliage, with an occasional plant of *Acacia lophantha*, make a very pretty and effective bed, whilst for the lighter varieties a green carpet, as *Camomile*, *Mentha*, &c., or, better still, the blue *Viola*, may be used. A plant I can thoroughly recommend for dotting about amongst masses of blue *Viola* is *Sisyrinchium californicum*; its flag-like foliage and long spikes of creamy yellow flowers stand well up, and form an effective contrast to the blue carpet; the same *Viola* may also be used to advantage as a groundwork for large beds of scarlet and

pink Geraniums the best dot plants are white *Marguerites*; struck in spring and turned out of 3 inch pots, they make large bushes quickly, and the dense sheets of white rising out of the bright colours of the Geraniums have a very pretty effect. For smaller beds, *Eucalyptus* and the sweet-scented *Tobacco* may be used instead of *Marguerites*. Nice little plants of *Fuchsia*, with compact bushy heads, are also very useful, and can be worked in according to colour in beds of *Viola*, dwarf *Ageratum*, *Iresine*, *Heliotrope*, and the like. A pleasing combination for a large bed is a groundwork of dark purple *Petunia* interspersed with occasional plants of the large variegated *Abutilon*, and yet another is a carpet of dark *Heliotrope* dotted over with *Centaurea candidissima*. For green, feathery foliage, to be used where bright variegation predominates, nothing is better than *Acacia lophantha*. The above list might, of course, be largely extended, but the plants enumerated are within the reach of all who have a greenhouse, and wish to furnish some pleasing combinations for the summer decoration of the flower garden. E. B.

Violets after the snow.—Mr. Allan's account of the flourishing state of his Violets must refer to those that he manages so admirably under the

glass-lights which he places so prominently in the eye of the sun, at Gunton Park, throughout the winter and the early spring. Were it otherwise, then indeed must Gunton be a weather Paradise, free from the chilling snows and cutting frosts that have played such havoc with Violets in the open this winter. The three sorts of which Mr. Allan has sent you flowers are also those that have suffered most in the open this winter. Borders of Marie Louise, Neapolitan, and Comte Brazza, studded with bloom and well clothed with foliage before Christmas, are now flat with the ground and brown, as if boiling water had passed over them. Whatever may be said with truth of the snow keeping Roses warm and snug for a month or more at a stretch, it is abundantly proved by results that these best of all Violets have not yet learned the art of sleeping for the same period under the snow and reappearing as fresh and fragrant as before. On the contrary, they have resented the snow wrappings and all its chilling works of successional thawings and freezings. The Czar, as might be expected from its semi-Arctic name, and Queen Victoria, probably a close blood-relative of The Czar, as becomes it also, have borne their long period of hibernation with impunity, and come forth breaking into bloom—which, however, seems in no hurry to fully open.—D. T. F.

Double Primroses.—Of claret-hued kinds, other than the old double crimson I have grown one here, under the designation of Scotch red. Apparently, it is a robust sort in its northern home, but in the hot south it soon went the way of all double Primroses. The flowers were of a reddish chestnut hue. They opened at first small and single, but later became good doubles, though not large. There is also a variety variously known as the Scotch purple, crimson-purple, and purple, which has rather smooth leafage, and produces its blooms in clusters on semi-Polyanthus stalks. This is early and free, and one of the very best where it can be induced to thrive. The flowers are of a reddish purple, and might be by some termed claret, or port-wine coloured. The true double purple has distinctive flowers, each petal being marked with a tiny white spot; the foliage is long and fairly smooth. Compared with single Primroses now so fine, so varied in colour, so early in bloom, and withal so robust and free, it is very doubtful whether doubles, even of the most striking form, can hold their own now. The single kinds are also easily raised from seed, and hundreds of plants of them will involve less trouble and anxiety than will a dozen choice double Primroses in pots. My plants, in hundreds, after being half-drowned in snow water, are bursting into very early and beautiful bloom, such as no doubles could equal.—A. D.

SHORT NOTES.—FLOWER.

Saxifraga Burseriana.—This beautiful little Saxifrage is grown admirably at Chiswick, where large clumps of it in pots in cool pits may be seen now just coming into flower.

Crocus Imperati. This beautiful early Crocus may be seen at the present time in full flower on the rock-work in the Royal Horticultural Society's gardens at Chiswick.

Canna Gloire de Lyon.—This is at once the hardiest and darkest variety with which we are acquainted. In growth it is remarkably upright, the leaves erect and pointed, and of a beautiful deep red colour.

Cyclamen Coum vernum.—This pretty little gem with its reddish purple blossoms may now be seen flowering freely in a shaded nook in the gardens of the Royal Horticultural Society at Chiswick.

Canna Premiers de Nice.—Anyone desirous of procuring a yellow-flowered variety of Indian Shot cannot do better than procure this. In habit it is very dwarf and compact, and throws up its beautiful yellow flowers in great abundance.

Galanthus nivalis præcox.—A very pretty form of this popular spring flower is now to be seen in fine large clumps on the rock-work at Chiswick. It well merits its name, as it is much earlier than many other varieties growing in close proximity to it, and this character it has maintained for many seasons.

Lavatera arborea variegata.—We saw the other day at Chiswick some plants of this handsome Malvaceous plant that had been lifted from the open ground in the autumn. A peculiarity of this is that when planted out during the summer months, the foliage turns quite green and remains so. On being again lifted and potted, the variegation gradually returns and makes it a very effective plant for horse-decoration. It is easily raised from seed, which comes quite true

Iberis from the mountains of Greece.—This beautiful dwarf little Iberis is now in flower in one of the hardy pits in the Royal Horticultural Society's gardens at Chiswick. It is the earliest of all the family, but difficult to get a stock of, as it flowers so freely that no cuttings can be had, and we have never seen it ripen seed. Perhaps Mr. Maw could give us some information regarding it, as I think it was he who introduced it.

Globularia Alypum.—To the genus *Globularia* belong about seven European species or varieties, all of which, except *Alypum*, are dwarf evergreen alpine plants. Their flowers are of various shades of blue, and are borne on stems from 2 inches to 10 inches in height. *G. Alypum* is, however, an erect, evergreen, twiggy bush, from 1 foot to 3 feet in height, and frequently as much through. It has obovate, spatulate, glossy dark green leaves from half an inch to 1½ inches long, clothing the entire length of the woody stems. Its flowers, which are solitary and terminal, are about the size of a sixpence, and pale blue, shaded with deeper blue on the outer portion. This species is usually found in extremely narrow fissures of calcareous rocks bordering on the sea—so narrow, in fact, that it is almost impossible to get it extracted with roots sufficient to enable it to grow. On my last journey in South Europe I was, however, fortunate in meeting with a station where some were growing on a stony tract on a hillside. These have become nicely established, and are now flowering. It appears to grow well in peat, loam, and sand in about equal quantities, but it should be placed tightly between two pieces of limestone. It should also be in a warm, sunny position on rockwork or at the foot of a warm, sunny wall. The finest plants of it I ever remember to have seen were at Villefranche, on the borders of Spain. They were growing near the butresses, &c., of the fortifications—large bushes, bearing a profusion of lovely, delicate blue button-like flowers.—R. POTTER, York.

Violets.—Our treatment of this differs somewhat from that recorded by Mr. Uphill (p. 119). We find that they (especially Marie Louise) do not produce clumps sufficiently large either for sale or home work from cuttings the first year. Therefore, when the pits are cleared of them in spring we divide the plants into very small pieces, and select the best and freshest crowns for planting in open quarters. They are generally put on ground on which Cauliflowers grew, or such crops as had been fairly well manured the previous season. They also receive a dressing of some artificial manure when planted, repeating the dose twice or thrice during the growing season. In order to keep our stock from deteriorating through age, and to keep up the required number, we annually grow several thousands from cuttings. These are selected runners taken off when putting the plants under glass in October. They are laid in thickly in the open ground. By February they are rooted, and soon afterwards are planted out under Apple and Pear trees, where most of them remain until the following spring, when they are lifted, divided, and treated in every way the same as those that have been under glass, and where, as a matter of course, they will be placed in the autumn. Plants thus divided are our sheet anchor, and by these means we ensure extra strong clumps that afford us very large quantities of fine flowers nearly, if not quite, all the year round.—J. R.

Preservation of native plants.—In THE GARDEN (p. 101) Mr. Webster, author of an excellent book upon British Orchids, speaks about the protection of your native flora, and mentions the efforts that are being made in Geneva to protect wild plants. Let me add that our work extends beyond the limits of our own country, and that by means of our pamphlets, of the newspapers, of conferences, and of correspondence we have already directed the attention of many foreign naturalists to the importance of this question as it affects their own country. Since we founded our society we have had the pleasure of getting from many of the countries of Europe information, which shows us that this question has been brought to the front by our publications. Even in England, three years ago, we got from the Natural History Society of the Midlands an address of sympathy, which concluded with the

expression of the wish that some similar society should be established in England. We got once from some botanists in Brazil information about Orchid destroyers, who were sent from European horticulturists to report on some rare Orchids. We were told that some of them, in order to render the species rarer and dearer, destroyed all the plants which remained, and sent their examples to Europe as "the last" (similar occurrences have also taken place in Switzerland with alpine plants). We wrote immediately to Rio de Janeiro, and we had the pleasure of receiving an answer to the effect that something would be done to prevent such vandalism. I am glad to hear that Mr. Webster is of our opinion, and I hope he will become a member of our society, which wants the names of those who protest against the destruction of natural objects. But I feel the necessity of further aid, and of asking in THE GARDEN if there are not in England native lovers enough to form an English association for the preservation of plants. I have for a long time heard complaints of the destruction of plants in England as in Switzerland. Many of your greatest botanical and horticultural authorities have said to me, "We want here in England such a society as yours." We had, I can assure you, great trouble here to found the society, because we had to deal with people that are not very enthusiastic in regard to plants. But in England—I do not believe that anywhere in the world could there be found a people more enthusiastic in regard to plants and flowers than the English are, and I can say that we found greater success for our ideas of protection in England than in any other country. I hope the time will come, and soon, when our Association for the Protection of Plants will have a sister to fraternise with in England. All those who are interested in these questions can get our reports gratis at my office.—H. COLEMAN, Geneva.

FRUIT GARDEN.

W. COLEMAN.

DUCK'S-BILL APPLE.

IN THE GARDEN (p. 99) "J. C. C." has done good service to orchardists in drawing attention to this valuable late variety. With us it is grown extensively as the Winter Pearmain, in Sussex as the Duck's-bill or Sussex Scarlet Pearmain, and although some confusion exists, it is just questionable if this is not the oldest Apple on record, consequently the original of all the Pearmains, a numerous and most excellent family. Indeed, were I confined to one section for my yearly supply of fruit, I have often thought I should plant in duplicate all the best varieties, commencing with the old Summer and Worcester Pearmains and winding up with the Herefordshire and Mannington's. All the varieties, especially the old ones, are very hardy, moderate but good growers, and generally carry good crops of fruit, a large tree of the Duck's-bill with me, probably sixty years of age, having borne more or less heavily each season since the year 1860. "J. C. C." is quite correct in saying the sample sent to him is still sound and looks like keeping till April; nay, more, if placed in a cool even temperature he will find it plump enough in May, if not later, for only last season I placed two of the most beautiful samples I ever saw in a desk in my room, where, in the dark, they laid on their rich crimson streaks and spots and kept sound till June. I then took them out, and not only was their flavour of the highest quality, but the aroma they left behind in the desk remained for months afterwards. I have been looking over my stock, of which I have several bushels from my old standard, and find they are just changing from dull green to pale yellow, and the rich stripes and sunny cheeks

will soon become bright crimson, when the fruit will be delicious and an ornament on the best appointed table.

For the guidance of planters who do not know the Apple I will quote a description of it from our great authority, Dr. Bull, who says:—

The fruit is 3½ inches wide, the same in height, of a true Pearmain shape, somewhat five-sided towards the crown. Skin smooth, greenish yellow, marked with streaks of dull red on the shaded side, deep red next the sun, and strewed with russety dots. Eye large and open, with short segments set in a deep basin. Stalk a quarter of an inch long, inserted in a deep funnel-shaped cavity lined with russet. Flesh yellowish, firm, crisp, juicy and sugary, brisk, piquant, and pleasant. Quality highly esteemed for culinary purposes, but may be placed on the dessert table with credit. A very handsome fruit, and always fetches a high price in the market. Season from December to May.

When I state that the writer of this description did not care for sensational examples, but gave preference to good average fruit, readers will gather that this old variety is worth looking after, not only by private consumers, but also by growers for market. At the present time there is a strong feeling in favour of the fine samples imported from the colonies, and, strange as it may appear, leading dealers and salesmen are prejudiced in their notions of good Apples and their proper season, particularly those of home growth. This prejudice must be got over, and it is needless to say the task rests with growers, who must devote their attention to a few of the best sorts which do well in their own localities, and are acknowledged by the middlemen. Of these they must produce quantities, and send none but picked samples to market. I do not wish to prevent them from buying and planting new and mid-season sorts, but if they would redeem the ground already lost, they must cultivate acres of the best early and late varieties which have quality as well as good looks to recommend them. The Pearmains for culinary or dessert purposes span the whole Apple season, and being with few exceptions such good croppers and so thoroughly hardy, it is hardly possible for anyone to make a bad selection from the score or more varieties now met with in good fruit catalogues. First on the list in point of earliness come the handsome Worcester and Scarlet Pearmains, fit for use in September and October, and always likely to command a good price, as they can be rushed into the market before the colonial fruit reaches our shores. Then follow a few delicious mid-season sorts, and last, but not least, we have Adam's Pearmain, from December to May; Baxter's Pearmain, from November to March; Claygate Pearmain, equal to the Ribston Pippin, from Christmas through March and April; Lamb Abbey Pearmain, from January to April; Bolehin's Pearmain, which keeps well till May; the Golden Winter Pearmain, quite distinct from King of the Pippins and the Winter Pearmain of the Horticultural Society; the old Herefordshire Pearmain, a valuable Apple, sometimes called Royal Pearmain, in use from December to March; and, as a matter of course, the Duck's-bill mentioned by Blomefield in his "History of Norfolk," as being the variety which furnished 200 Pearmains and four hogsheads of cider of Pearmains to the exchequer for use at the feast of St. Michael's yearly.

SHORT NOTES.—FRUIT.

Pear Fortunee Boisselot—This when well ripened is a most useful variety for dessert during this month. It is of large size, flesh white and melting, very juicy, and possessing a pleasant aroma.

Apple-tree flower-buds are so stout and abundant even now that it will be well to prune liberally to enable the trees to carry the forthcoming crop. Tree heads fill so

quickly when doing well, that it is wiser to err in the direction of free thinning than to spare the saw; indeed, to spare the saw is to spoil the tree. A. D.

Apple the Sandringham.—This very fine new variety is now in good condition. It is of large size, light green, flushed on the sunny side, keeps well until March, and is well worthy the attention of fruit growers at the present time.

Filberts.—I observe trees of these in abundant bloom already (Feb. 4). Should this free blooming be indicative of a large crop of Filberts and other small nuts, the indication is welcome. It would be interesting to learn how the Filbert bushes look in Kent.—A. D.

RENEWING VINE RODS.

Those who have but little room for Grape growing, and who like to grow as many varieties as possible, may, by adopting the following system of management, gain results equal to those secured by the extension system of training, and still confine each Vine to the limits usually assigned to it when grown on the single-rod principle. The advantage of the extension system is that the wood from which the fruiting laterals spring is young and vigorous, and the buds stronger than those produced by old, spur-pruned rods. What we have to do, therefore, is to keep up a succession of young rods, and still get a full crop of fruit every year. By a little management this is easily done. If the Vines are about 4 feet apart a succession of rods can be brought on, each of which will in its turn bear fruit of the best quality for three or four years. In the first year of bearing, which should be the fourth year of growth, these young rods should only be allowed to bear half a crop, but this will not lessen the average crop, as the top half of the old rod on the same Vine should be allowed to bear fruit for that year. Of course, all buds should be rubbed from the lower half of this old rod to give room for the fruiting laterals of the young one, and at pruning time it should be cut out entirely. In the following spring a new one should be started from the strongest, well-placed bud that can be found. It may be thought that too much room is required for working this plan, but that is not the case; the young rods take very little room till they begin to bear fruit, as their laterals may be frequently stopped. Some years ago I worked three vineries in this way, and was well satisfied with the result; the Vines so treated bore larger bunches and berries, and heavier and better finished crops than the old rods had borne for many years. I gradually removed the old rods, and now there is not one in these houses which is more than seven years old, though the stools must be over twenty. If any of your readers, who are now depending on the produce of old rods that seem to have lost vigour, will adopt this system, they will soon see a great improvement in the quality and quantity of the fruit obtained. T.

APPLES FOR SMALL ORCHARDS.

ALTHOUGH not so enthusiastic in the matter of Blenheim's (p. 74) as to wish for an orchard composed entirely of that variety, I am inclined to think that, in the matter of Apples, as with other fruits, plants, and vegetables, we are rather overburdened with varieties, and that a certain restriction in this direction at planting time would be beneficial. In large places where space is no object it is very well to have a large collection to compare notes, and to be ready with a few extra-sized fruit on an emergency; but in the majority of cases the planting an endless number of varieties brings neither pleasure to the gardener nor profit to the employer. With respect to the particular kind of tree to be used, there is certainly nothing like good standards where the filling up of the fruit room is a consideration and where Apples are largely used, and I do not think either bushes or pyramids will ever hold their own against them, for there are few places so small

that cannot find room at any rate for a small orchard, and the trees might be planted well enough to admit of the spaces between them being utilised for bush fruits. In planting a small orchard, I should confine myself to ten varieties—five dessert and five culinary—viz., Devonshire Quarrenden, King of the Pippins, Cox's Orange Pippin, Claygate Pearmain, and Cackle's Pippin for dessert; and Lord Sutherland, Warner's King, Blenheim Orange, Hambleton Deux Ans, and Norfolk Beaufin for kitchen work. To the planter in doubt for some extra trees to fill up a corner, I would say plant more Blenheim Oranges and King of the Pippins. This latter variety was subjected to a considerable share of hostile criticism at the time of the Apple congress, owing to the high position then assigned it, and unjustly, I think, for in very many places it is deservedly at the very top of the tree. With a little extra attention at root and branch it produces very handsome fruit, a little over medium size, and is in good condition for dessert nearly three months. The tree is healthy and vigorous, and a great and constant bearer. Taken on the whole, I think the ten varieties named will be found to possess all the necessary qualifications in their respective seasons, either for dessert or kitchen purposes, and in addition they are all handsome in appearance and capital croppers. Where space is a consideration, and only a limited area can be devoted to the orchard proper, some of them, notably Cackle Pippin, Blenheim Orange, and Hambleton Deux Ans might with advantage be planted on the lawn or in open spots in the shrubbery, as, in addition to other good qualities, they possess the merit of growing into very handsome trees. E. B.

SEASONABLE WORK AMONG FRUITS.

VINES.

THE work in this important department is now increasing rapidly, and an effort must be made to keep every detail well in hand, for, next to the performance of every minor matter in a sharp, business-like way, we must not overlook the fact that the proper time is a factor which often makes or mars an otherwise good system at the end of the season. Just now Vines in the early houses are not only gaining strength under a few hours' genial sunshine, but they are making rapid headway, and a fine month will redeem much of the time lost during the trying month of January. Here, then, timely help must be given first of all by giving the chink of morning air to let out vitiated moisture, by gradually increasing it, and, finally, by closing very early with sun-heat to secure quick growth during the afternoon. Fire, of which we have had more than enough, by this means may be economised, and yet the temperature being high, the syringe may be freely used to break up young colonies of pests which its baneful influence has brought into existence. Many people never wet their Vines after all the buds have started; but this has been an exceptional season, and each man must solve for himself the problem as to whether he will stand firm to his crotchet or stoop to conquer that inveterate enemy, red spider, by an occasional bath quite up to the flowering stage. Pure soft water judiciously applied is an invaluable element, and when it is just tinged by the little bag of soot lying at the bottom of the cistern, it becomes a gentle tonic and a mild insecticide. If water has not been given to internal borders since the Vines broke, a quantity equal to a rainfall of 3 inches, provided they are well drained, will tell beneficially in a few hours, and most likely help the Vines over the setting process. This, as a matter of course, should be equal to the maximum temperature of the house, otherwise it may not produce the desired effect upon the hitherto dormant roots, as it is a well-known fact that vigorous root action invariably ensures a good set of fruit. If external borders have been well covered with dry, warm leaves, which in their turn have been protected from the elements, they will take no harm, as the

roots are now only just beginning to move; whilst those inside, which are more advanced, may be drawn to the surface by spreading down the old fermenting material immediately after the borders are watered.

Disbudding, stopping, and tying down also require timely attention, otherwise a march may easily be lost and never regained. The first operation should be performed piecemeal as soon as the best shows can be discerned; the second, when the shoots have attained their proper length, when pinching out a point not larger than a pin's head will produce the desired effect without robbing the Vines of an ounce of vital force. This term may not be quite correct, but it answers my purpose, as I wish to see an end put to the unwise system of allowing the shoots to run to waste, and afterwards weakened by cutting back to an ugly stump, followed by bleeding. Once stopped at the second or third leaf beyond the bunch, the first set of point laterals may be allowed to extend until every bit of trellis in due course will be furnished with foliage. Here again some judgment must be brought to bear, as it will be necessary to allow for the full development of this lateral foliage without becoming crowded, and so impeding the free circulation of air. Tying down and the removal of superfluous or inferior bunches generally go hand in hand. A bright afternoon, when the shoots are slightly limp, is the best time to draw them downwards, and then the pressure should be very slight—so slight, indeed, at first, that the ties should little more than prevent them from ascending to the glass.

Fertilisation.—Hamburgs do not often receive this attention, but mixed sorts, notably the Sweetwaters, Foster's Seedling, and the Frontignans, should not be neglected. Hamburg pollen is always preferred, and the act of collecting it is often advantageous to the pollen parent, which does not always set so freely as one could wish, otherwise so many stoneless berries would not be met with at the final thinning. If Hamburg pollen is brushed into a small box and kept dry and airtight, it is often found useful in the early Muscat house, when artificial fertilisation of this fine Grape is of the greatest importance.

Succession vineries.—The Vines in these will now be on the move and in many places disbudded. General rules observed in the management of early houses apply to these in almost every particular, the only difference being a somewhat higher temperature, which the advanced period will now justify. When fairly on the move, 60° at night and 70° by day will be quite high enough for ordinary varieties, and these figures may be increased to 65° as the minimum by the time the bunches come into flower. As this stage is approached and the bunches begin to elongate, advantage must be taken of every bright and sunny day for running up the temperature to 75° or 80°, when the framework of larger clusters will result, and the progress made will not only justify, but necessitate moderate firing through the night.

Pot Vines.—If these are intended to produce not only the first ripe Grapes, but also to save the first set of established Vines, the Grapes should now be ready for thinning. Quality taking precedence of quantity, the bunches in the first place should be reduced to six, possibly to eight, according to the strength of the rods and the condition of the roots, for, unless these are in every way satisfactory, the attempt to obtain a heavy crop of black Grapes will be followed by disappointment. Of the two I should give preference to the smaller number of bunches, and then, provided the Vines are up to their work, not only will the weight in the aggregate be equal to that obtained from the eight, but the berries will be larger and the colour better. The thinning of Grapes is an operation which every grower, particularly of pot Vines, must manage in his own way. Hamburgs, which form the staple of the crop, vary more than any other family of Grapes. Some form close, compact clusters, and swell their berries to the largest size; others are loose in the bunch, and the berries, as a rule, are oval. The first, compara-

tively speaking, require heavy thinning; the second, possibly hardly any thinning at all. To lay down rules for the manipulation of these might mislead; therefore, knowing the character of his Grapes, every man should be the best judge of his own work when the time arrives for thinning. When a bunch is properly thinned, it should be free from small or stoneless berries, and those left should be sufficiently numerous to form a perfect cluster, free from spot or blemish, which will retain its form when cut and placed upon the dish. When the Grapes are thinned, lateral growths may be tied out and pinched to secure an even spread of foliage over every part of the trellis, and the richest food at command may be used as a top dressing for the roots. This should be applied little and often, and, as a matter of course, washed in with copious supplies of warm water or diluted liquid, always, be it understood, weaker than the roots of healthy Vines will bear. Stimulating liquid in moderation is a most excellent aid to progress, but when, in addition to the rich top-dressing and the ammonia rising from the bed, it is used too strong, the most valuable roots perish or become paralysed, the foliage flags under bright sun, and the Grapes, as a natural consequence, never colour. Vines in pots being subject to red spider, the syringe from this time forward should be freely used for moistening the walls, the stems, and foliage with pure, soft water; and time being an object, the temperature may range from 65° to 70° at night, from 75° to 80° by day, and a few degrees higher after closing with sun heat. Air in proportion to these figures being imperative and the weather fickle, the fermenting material surrounding the pedestals on which the pots are placed should be renovated at short intervals, not only for the benefit of the roots, but also to favour a free circulation without reducing the heat to an injurious extent.

Cut-back Vines intended for next year's fruiting should be shaken out as soon as the buds have started, and repotted in 7-inch pots for growing on. The compost for these should be good sound turf, bones, or old lime rubble, three substances that will form a substantial nucleus and remain sweet until the Grapes are cut eighteen months hence. Peat, leaf-mould, rotten manure, and other perishable substances are often used to give the roots a start, but they soon become light, spongy, and sour, and for this reason should be avoided. When repotted the pots should be plunged to their rims in a snug pit, and not too far from the glass, where they can have a steady bottom heat ranging from 75° to 80°. An early and quick growth being important, a corresponding degree of top heat and plenty of atmospheric moisture must also be supplied, but the roots having been so recently disturbed very little water must be given until new ones have taken full possession of the soil, for much as Vines in full growth rejoice in an occasional deluge, they soon lose the few roots they have when as pot subjects in a comparatively dormant state they are over-watered. If two shoots have started from the crown of the old eye, the retention of both for a time favours root action, but the weakest of the two must be checked and entirely removed before the time arrives for the first shift forward.

Vine eyes put into small pots or inserted in squares of turf last month may now be plunged in a steady bottom heat of 80° in a moist-growing pit, where dewing with the syringe will keep them wet enough for the present. Vines may be struck in a much lower temperature, but much work having to be performed in a short time, propagators always prefer stealing a march in the spring, and so successful are some, that they invariably succeed in producing fruiting canes from eyes of the current year. The great secret of success in large manufacturing establishments is bound up in ripe wood, an early start, and a steady bottom-heat, which never varies. Private growers of a score or two of eyes can always secure the first and second, and start with the third at high pressure. All goes well until the stored-up sap is exhausted and young roots are forming, when, owing to the fleeting nature of their fermenting materials, the heat

suddenly declines, and nine-tenths of the pseudo-Vines are lost. This is the stumbling-block with many small growers, who should either provide two plunging beds for alternate renovation or start at moderate speed, which they can retain until the young Vines are well furnished with roots and leaves. Cut-and-dry calendar writers of the past have been too fond of cooking and hashing, and telling people what to eat and drink, but they have not told them what to avoid. Half the young gardeners in the kingdom can repeat the contents of old-style papers by heart, but it is questionable if lists of failures, causes of failure, or how not to do it might not form a very useful negative guide. The black bit to be avoided by the amateur propagator of Vines is the sudden drop from tropical to temperate heat just when the road to success turns in the opposite direction.

The latest Vines pruned, cleansed, and resting must be kept as quiet as possible for some time yet. It is not difficult to excite late varieties from which the Grapes were cut at Christmas, but a short rest means a weak and uneven break; consequently it is best to keep them quite cool until the buds begin to swell, when, like giants refreshed, they will break freely and make vigorous progress. Meantime, in the event of internal borders requiring renovation, preparations may be made for the performance of the work as soon as the sap is again on the move. Early and mid-season borders can be turned out as soon as the Grapes are cut and whilst the foliage is fresh, but late ones cannot be disturbed before the leaves fall, and then it is best to defer the lifting and re-laying of the roots until returning spring starts them into new life. If fresh turfy loam, bones, and other ingredients can be chopped up and thrown into a heap to ferment, a very important point will be gained, as the newly-laid roots, washed home with water at a temperature of 90°, will have the benefit and healing influence of a mild hotbed.

GARDEN FLORA.

PLATE 583.

ONCIDIUM JONESIANUM.*

THIS distinct and handsome *Oncidium* belongs to a section which contains but a few species, characterised by short pseudo-bulbs and Rush-like leaves. *O. Jonesianum* was discovered by M. Louis de St. Leger on Monte Grasso, Paraguay. It was distributed by Messrs. Horsman & Co., of Colchester, and named by Prof. Reichenbach after the Rev. Morgan Jones. Its pseudo-bulbs are small, and its leaves, which taper to a long sharp point, are deep green, and from 3 inches to 9 inches in length. Until quite recently this species had only produced simple drooping racemes of bloom, but during the last few months we have received long branched spikes of it bearing nearly forty flowers, a condition in which it is strikingly attractive. The individual blooms measure about 2½ inches across; the sepals and petals, which are waved at the edges, are large, creamy white, blotched and spotted with red or reddish brown. The lip is large, broad, and flat, the front lobe being wholly pure white in some varieties, in others spotted and dotted with reddish brown. The small side lobes of the lip are bright yellow dotted with red. Its blooming season is usually from June to November. The majority of terete-leaved *Oncidiums* are small-flowered and by no means showy; therefore few of them have been preserved. *O. Coboleti*, with light canary-coloured lip, and *O. juncifolium* and *O. brachyphyllum*, both natives of Mexico, are about all that are in cultivation in this country at present. *Oncidiums* are for the most part easily grown, and *O. Jonesianum* forms no ex-

* Drawn for THE GARDEN by H. G. Moon, in Mr. R. J. Measures's garden at Camberwell, on July 20, 1886, and printed by G. Severeys.

THE ART. ILLUSTRATION

ception to the rule. It thrives best and displays its beauties to the greatest advantage when grown upon a block or in a basket suspended head downwards from the roof of the Cattleya house. It should be well exposed to sun and light, and should be treated to an abundant supply of water during the growing season. W. H. G.

KITCHEN GARDEN.

W. WILDSMITH.

KITCHEN GARDENING.

OF late years increased interest is evidently being taken in regard to kitchen gardening. Young men who at one time were anxious to get "under glass," begin to think that after all kitchen gardening is not so despicable a thing as they once thought it. The fact is, their eyes are beginning to be opened, and though still in a little uncertainty as to whether or not it is dignified labour to plant a Cabbage, they have a strong inclination to try their hand at such work, and I for one applaud their resolution; I also sometimes think that we are ourselves to blame for the lack of interest that young gardeners take in the vegetable department. As a matter of course, in all large gardens young men must live on the place, and the houses must be attended to by regular hands, but it does not of necessity follow that they could not have a day occasionally in the vegetable or other departments. My rule is to let them have a turn at every description of work in the garden, and as they are engaged on these conditions, there is no bother about the matter; in fact, they enjoy the change. It is not to be expected that the would-be-thought-clever young fellow, who has gained admission into the fold by means of a premium, would agree with one of the articles of my creed, namely, that it is just as creditable to grow a good Tomato or a Cauliflower as it is to grow a fine bunch of Grapes or an Orchid, but it is true nevertheless, and he will soon have to recognise the fact by practical experience, or else seek some other calling, as gardening, like many other professions, has grown to be more of a pounds, shillings, and pence matter than it used to be. The artistic and ornamental branches of it were never in greater request, but there must be plenty for the money, and in the near future it will be only "all-round men" who will stand the least chance of rising to the highest positions. To young gardeners I would say, never think that your dignity suffers by digging a few rods of ground. Devote the same pains to thinning out Carrots, Parsnips, Onions, and the like as you would to thinning out the seeds of Mignonette in pots, disbudbing show Chrysanthemums, or thinning Grapes. Plant out Cabbages, Cauliflowers, Lettuces, and any other vegetable with the same amount of care as you would pot the choicest plants. Above all, get thoroughly rid of the notion that you are above doing what in gardening parlance is called "labourer's work;" then, as a set-off to what you may at present sometimes consider to be hard work, or such as you ought not to be called upon to do, you may with good reason hope one day to attain a position in the gardening world worthy of your devotedness to every branch of your calling.

Wintering Beet.—A considerable stock of Beetroot has wintered remarkably well so far laid in beneath trees in light loose soil. This is a good plan where it is specially desired to keep the roots fresh and plump, and when carefully lifted from the kitchen garden and so laid in, the shoulders being well covered with soil, and the tops in hard weather with leaves, it is remarkable how little the roots feel the lifting. Carrots and Parsnips also

keep well in the same way; frost, severe out in the open, is often comparatively light under overhanging trees.—A. D.

CULTURE OF SEAKALE.

WHERE a constant supply of this vegetable has to be maintained from the middle of November up to the same time in April, some forethought is required to prepare sufficient plants of quality good enough to keep up the supply to meet the demand of such a long season. Where recourse cannot be had to buying a stock of plants yearly prepared for forcing, a supply can easily be raised if the following details are carried out: Seakale delights in a strong moisture-holding soil approaching clay. In such a soil, if manure be freely applied, the plants grow freely, producing large leaves, which in turn develop good crowns for the following season's use. An easy, cheap way to procure a stock of plants is by growing them from seed, which should be sown the first week in April on land that has been previously deeply dug or trenched and manured the winter previous. Roughly rake over the ground, and with the corner of a hoe draw drills 2 inches deep and 15 inches apart; in these sow the seed thinly, and cover it by filling the soil into the drills, rake the whole over again to remove loose stones and make all neat; the seed will quickly germinate and grow; as soon as the plants can be handled thin them out to about 6 inches apart in the rows; better not allow them to be crowded; rather grow fewer in number. After this nothing beyond hoeing between the drills to keep down weeds will be required the first summer. Any time during February the following year the plants should be dug up and replanted, preserving the roots in good condition. Manure the ground freely, and dig deeply or trench as before. If this be done in the autumn or winter so much the better, and at planting time it will simply require forking over as planting proceeds; the rows should be 18 inches apart, and the plants at least 1 foot from each other. Previous to planting, the roots should be selected according to their size, retaining the largest in one batch, while the small ones should go together and can occupy rather less space. The reason for thus selecting the roots in this manner is that some of the largest after this season's growth will be ready for forcing, while the smallest will not be strong enough for another year, and if all are mixed more labour is entailed in digging them up and sorting; whereas if they are classed according to their sizes no trouble need be found in taking them up. The best plan is to dig the space required, then stretch a line, and with a spade chop out the space for each plant in a perpendicular manner; the roots should be buried under the soil at least an inch or two, the crown or growth shoot having been first cut off. This operation is to prevent the growth of bloom shoots being developed. If this takes place instead of leaf growth only the plants are spoilt for the next year's expectations of forcing. Certainly the cutting off of the crown should be done, say, half-an-inch under the point where the succeeding growth springs from. Plants so treated will make leaf growth only, and many will be of sufficient strength to force the following season. If not commencing too early with them it is always best to have some extra strong to depend upon for the earliest supplies. The smaller roots need not be taken up this season for replanting if time or space is an object, but the crowns should be all cut over before growth starts to prevent them blooming, and by the end of the next autumn a good stock of plants will be available, and can be kept up from this time onwards if properly attended to. After being forced, such treatment should be as follows: Any time after the Kale has been cut from them, they may be replanted at similar distances and in the same manner as described before, thoroughly well manuring the ground; if the roots are extra thick, they may be split down the middle, and if a larger stock is required, they should be cut into lengths of from 9 inches to a

foot; any pieces of the roots 3 inches long will grow, and in time will make nice plants if necessary to use them; but once a sufficient stock is secured, it can generally be maintained without using up all the root pieces.

Many are the methods adopted to force Seakale. In very few instances is the old-fashioned plan of making huge heaps of manure and leaves resorted to. No doubt the produce of such a method is of capital quality, but where time is an object of some importance, this system is not economical; besides, the appearance of such materials on the ground is not altogether good, but where no other convenience for the purpose is available, such a method must be practised. For the earliest supplies some roots may be placed in 10-inch or 12-inch pots with pots of the same size turned over them; these can be placed by the hot-water pipes in the plant stove or any house where a good heat is available. For a succession to be maintained until April there is no better place than the Mushroom house, where such structure can be partly devoted to the growth of Seakale. The time to renew the supply of roots must be guided by the demand. For a fair production, about once a fortnight is suitable, taking up the roots so that as little damage as possible may happen to them. We find the lighter the character of the soil the more tender is the Kale, and not so liable to that strong taste which sometimes is found in this vegetable. We therefore use rotted leaves entirely, and over each crown we place an inverted pot, which more thoroughly excludes the light. Some cover the roots entirely with fresh leaves, which answers very well; but there is more labour entailed in this way than by using pots. When the roots are all cut over once they should be removed, and laid in until a favourable opportunity presents itself to plant them in their summer quarters.

Some persons allow the roots to make a second growth, but, except the stock is small, it is not wise to allow second growths to form, as this weakens the roots. The latest supplies can be had from roots outside which have not been lifted. As soon as they show signs of growth in the spring cover the crowns with coal ashes of sufficient height to thoroughly exclude light. Over this turn an empty flower-pot. Capital late supplies may be had by such means. E. M.

MAIN-CROP PEAS.

THE rows should be isolated, and be ranged north and south, so that the sun may shine on both sides, as in our climate we never have too much sunshine for Peas if the roots are well placed; and in the cultivating operations now being carried on it is a good plan to set out the places for the rows of Peas and give the land a special preparation. In some gardens this may be unnecessary, the ordinary soil and the ordinary culture being of the best kind. Still, in difficult seasons it is as well not to leave anything to chance. What Peas require to enable them to stand against a dry, hot time is depth of soil of a mellow, genial character. Manure, even when used liberally on the land, will not compensate for loss of depth in the soil, and I think Peas dislike too much manure, especially if fresh or inclining to rankness. I have generally succeeded better by the use of composts, of which manure, blended with earth and the refuse matter from the rubbish-heap, formed the chief constituents. This compost, freely worked into the trench where it is intended to sow the Peas, never fails to produce satisfactory results.

Thick sowing is an evil always, as it prevents the plants, even when the rows are placed at wide intervals, from doing their best. I know of no better plan than drawing a drill with a 6-inch-bladed hoe from 2 inches to 3 inches deep, varying the depth between the figures given according to the season and the soil. Thus, say in March, if the soil is cold, draw the drills only 2 inches deep, and cover with mellow surface soil. Later in the season, when the soil is warm, draw the drills the full 3 inches deep, to give the roots a chance of getting down a little earlier to the cool, moist compost below. Of course in hot weather mulching with long littery manure is

a most useful, and in some soils an indispensable, expedient. It is also very important that all Peas should be gathered as soon as they become fit for use. Leaving the pods on the plants to get old takes the stamina out of the land, and the plants also, in a very expeditious manner. If the land be properly prepared now and the rows of Peas mulched at the beginning of the dry season, watering will not, as a rule, be necessary, so that in preparing the site now much heavy dragging of water is obviated in future.

As regards varieties, I have nothing to say beyond this, that anyone who casts aside a well-tried old variety to make room for something new or novel at a considerably enhanced price will probably regret it. *Huntingdonian*, an improved *Champion* of England, *Veitch's Perfection*, *No Plus Ultra*, and *British Queen* are excellent main-crop Peas, which may be bought at a reasonable price per peck or quart, and for the supply of a family they are thoroughly reliable.

E. HODGAY.

EARLY FORCED POTATOES.

The early Potato is one of the most useful vegetables which can be grown, for it is an everyday requisite in all families, always sure to be appreciated. In gardens where forcing is carried on during the spring months early crops may be grown at a trifling cost, and only a small amount of labour is required to grow a crop either in pits or flower-pots, provided a suitable temperature can be procured. Tubers may be had for use from the end of February or beginning of March, and from that time onwards during the spring until the earliest outdoor crop is ready to dig. Forced Potatoes usually take from fourteen to sixteen weeks from the time of planting until the tubers are large enough for use. The sorts of Potatoes to be grown should be the first thing which should be taken into consideration, some sorts being more suitable than others to grow under glass, both as regards earliness of varieties and quality of tubers. That which I consider to be a suitable Potato for forcing is one which grows dwarf, and produces a good crop of even tubers in proportion to its haulm. The pit which is to be used for growing forced Potatoes requires to be of medium depth, for it is useless trying to grow Potatoes in a shallow pit and not allowing sufficient head-room for the haulm, for as soon as the haulm reaches the glass the crop will be destroyed, especially in frosty weather. The plants should be grown as near the glass as possible, which will have a tendency to make the haulm grow stocky and firm, but at the same time, taking into consideration the height of the haulm, several sorts may be grown which will be found suitable for forcing. The varieties most suitable for forcing are the earliest kidney ones. The kinds which I have found to produce the best and earliest crops are *Early Bird* and *Rivers' Ashleaf*. The old *Myatt's Ashleaf* is one of the best for frame work. For late forcing *Covent Garden Perfection* will be found one of the most suitable varieties. Several different structures may be used for growing forced Potatoes. The most convenient pit is one in which chambers are constructed, so that fresh linings can be added at intervals to keep up the desired temperature, which should be as near 55° as possible. When pits are not at command good crops of early Potatoes can be grown in frames, the sides of which must be deep enough to hold 12 inches to 15 inches of soil, and allow 2 feet for the haulm. When the Potatoes are to be grown in frames, a good heap of fermenting material must be got together before making the bed. This should consist of fresh manure from the stable and about one-third of fresh leaves, which must be well shaken together, leaving them in a heap until they get what is termed well sweetened. Before forming the bed it is well to make a foundation of rough wood about 12 inches in depth, covering the same with small branches. When making the bed, which should be 3 feet to 5 feet high at back and 1 foot in front, tread it firmly. After treading the whole firmly and level place the frame upon the bed, and cover with 12 inches of rich soil. As soon as the temperature

declines to about 60° the Potatoes may be planted, a lining of hot manure being added to keep up the proper temperature. By carefully attending to the hot linings the heat can be maintained until the crop is fit to dig. It is well to plant the sets in boxes covered with light soil or sifted leaf-mould, and placed in a warm pit or house until they have sprouted an inch or two in length, when they will be ready to plant in the pit. The sets of the *Ashleaf* sorts may be planted 15 inches from set to set. Be careful not to break the young growths, covering the sets to the depth of 3 inches. Admit air upon all favourable occasions as soon as the plants commence to grow, to prevent the haulm from drawing up weakly, increasing the air as the plants grow stronger. When the tubers commence to form put a little soil round each stem to prevent the Potatoes becoming green. Cover up the frames at night to keep an even temperature. Early Potatoes may be grown in flower-pots with advantage, and especially where pits and frames are not at command, as the pots can be placed in forcing pits used for growing other crops, or in a vinery or Peach house, or any structure which is heated. Several sized pots may be used for the growth of forced Potatoes, but the most convenient size is a 10-inch one. The number of pots to be planted must depend upon the room at disposal; from three dozen to four dozen pots of that size planted at one time will produce a quantity of useful tubers. For potting materials mix loam, rotten stable manure, and a sprinkling of sifted leaf-mould, the whole to be well mixed together before filling the pots. Place a few pieces of broken crocks in the bottom of each pot, covering them over with a handful of dry leaves. Fill the pots half full of the soil, placing one Potato in the centre of each pot, covering it over with 2 inches of soil. Place the pots in some warm structure as near the glass as possible to keep the plants from drawing up weakly, and in a temperature ranging from 55° to 60°. When the haulm gets strong enough, additional soil is to be placed in the pots as an earthing up. Water should be sparingly given until the plants are strong and growing freely. When the crop is ripe and properly matured, the soil can be turned out of the pots and the tubers separated from it. Crops of forced Potatoes can be grown in deep boxes if pots cannot be had, treating the tubers the same as those grown in pots.

Horticultural.

Celery under the snow.—This in many cases has suffered severely, the centre—that is, almost the only valuable part—being rotted out, leaving the older leaves fairly intact. Our land is rather heavy, but the Celery was well earthed up and left in a sharp, narrow ridge, over which a thin layer of litter was strewn before the severe frosts. Thus the usual modes and means to ensure safe and sound keeping were adopted, but the results have by no means equalled the average, but so much to the contrary, that hardly one stick in ten is found safe and sound. It would be some consolation in misfortune to learn if others have suffered in a similar way, or have found any more safe and sound mode of keeping their Celery. I attribute its loss to its long period of hibernation under the snow, also to the amount of snow—fully 2 feet within a month—and the frequent thaws which took place during that period. The snow-water, as it is called, probably first utterly chilled, and then rotted out the hearts. Anyhow, they are gone, and will be much missed during the coming spring.—HORTUS.

Advantages of hoeing.—Too many persons who use the hoe suppose that the chief benefit derived from it is to kill the weeds. That certainly is an important work, and one greatly neglected. Weeds are not only in the way of cultivating the crops which we plant, but they rob them of much of the nutriment which they need. Hoeing, then, is an essential service in respect to destroying the weeds. There are other advantages, however, which are commonly overlooked. Let us see: 1. The loosening of the soil in the operation of hoeing is beneficial to the plants, as

much as the destruction of the weeds or more so. 2. Moisture abounds in the atmosphere during the hottest months, and is absorbed and retained most abundantly by a soil which is in the most friable state. 3. Then, again, pulverising soil enables it better to retain the moisture absorbed. 4. The soil, in order to be healthy and active, must have air. A light, porous soil admits air, and thus it is invigorated. 5. The sun's rays heat a hard soil much more quickly than a loose one, and the hotter the soil is, so much greater will be the evaporation from it. So that the hard soil is deprived of its moisture much sooner than one of a loose texture. 6. The soil that has been kept loose near the surface by the action of the hoe will receive and hold the rain-water that falls, while a hard soil will allow most of it to run off.—N.

PEA AMERICAN WONDER IN POTS.

Most gardeners have at some time in their career attempted the culture of Peas in pots, but unless an early gathering is wanted for some special purpose, they rarely repeat the experiment. Peas in pots do not pay for the trouble necessarily taken with them. However, if any reader is still disposed to test the truth of my assertion, or is undeterred by the experience of older men, he cannot do better than grow the *American Wonder*. They cannot be forced similar to *Kidney Beans*, but they may be forwarded considerably on shelves or front stages in late vineries, on the border of a light Peach or orchard house, or in any cool house, pit, or frame. Seed sown at once thinly in 9-inch pots, filled with rich loamy soil, will quickly germinate, and if well attended to in the shape of waterings, varied with frequent supplies of liquid manure, will yield one or two good pickings about a fortnight in advance of the earliest outside. Not less than twenty-five pots should be grown in a batch, or otherwise the dishes available at one time will be very small indeed. For frame culture the *American Wonder* is simply invaluable. Any rough pit or frame can be utilised for this crop, only a slight protection serving to ripen the crops from a week to a fortnight earlier, according to the season, than those outside. A very slight hotbed of leaves and stable manure may be used with advantage, placing on this about 9 in. of good loamy soil. If this cannot be carried out early in February, it is advisable to sow sufficient seed either in boxes of light soil or in small pots, placing these in any cool house or frame, or in gentle heat if need be. When about 3 inches high, they ought to be planted out. Shaking the plants clear of the soil does not appear to injure or check them to any appreciable extent—in fact, we prefer this plan to putting out root-bound patches from pots. Narrow deep drills are cut out with a spade, and each holds a good and fairly thick row of plants, the roots of which soon spread into the fresh soil that has been carefully disposed about them. Our rows are usually 15 inches apart, or three to each light, and between each line we grow *Early Paris Market Cabbage Lettuce*. These are dibbled in about 6 inches apart in the rows, and alone well repay the trouble taken, being more appreciated than any Lettuce we send to the table during the rest of the year. The Peas are supported with short spray rather more than 12 inches in height, and eventually with good cultivation present a very pleasing appearance. Being a *Marrow Pea* and very tender, it quite spoils the palate for any of the round-seeded sorts that may be grown for the earliest supply outside. The seed now being fairly plentiful and cheap, there is no reason why this variety should not be grown in any early warm border. W. GOULDEN.

SHORT NOTES.—KITCHEN.

Covent Garden Beet—This is a really first-class kind. It is handsome and tapering in form, of a deep crimson hue, and the flesh is soft and pleasantly flavoured. It is an old kind which has undergone careful selection, and is now found to be the best extant for market purposes. It is of a well selection, but is quite distinct.—A. D.

Snowball Cauliflower.—Seed of this early Cauliflower sown in a cold greenhouse has germinated freely in a fortnight, and will furnish strong plants ready to dibble out into frames by the end of March. After a month in frames, they will transplant with good balls of soil into a warm south border in cool soil, and then will turn in rapidly a few weeks later. This is really the whitest, earliest, and most

solid of all the Cauliflowers. I have grown it for fifteen years.—A. D.

Chairman Potato.—A quantity of this Potato, a seedling from *Magnum Bonum* and *Beauty of Hebron*, which had been put out in the field, and only just got into the store, has not only kept wonderfully well, but boils finely. No Regent can exceed it for quality or flavour. Chairman is a white, flattish round kind, somewhat resembling the Victoria in form and general appearance.—A. D.

TREATMENT OF SEED POTATOES.

I do not think many who fail to grow good crops of Potatoes are inclined to attribute this to their treatment of the seed tubers, but in my opinion more failures occur through badly treated seed than careless culture. Judging by the samples often seen planted, many must think that any kind of tuber will do for a seed Potato, as the smallest and most deformed tubers are frequently planted with the object of securing a good crop, but I cannot understand how this can be expected under the circumstances. Potatoes rejected for cooking should never be considered good enough for seed, as remunerative crops will never result from planting trash. Many of the seed firms, too, are not free from fostering this practice, as, in buying some of those new varieties so beautifully pictured in books, the seed is no more like the illustration than a Kidney Bean is like a Pea, and in opening the seed-bag, one cannot help wondering what can have become of all the large well-formed tubers. I can safely say I have received samples of new kinds of seed Potatoes which were greatly inferior in appearance to the refuse of ordinary kinds which were given to the pigs, and it tests one's faith severely to connect them with seductive illustrations. True, the small tubers of new and valuable kind may all be required to meet the demand for them, but I hold that the system of sending out inferior samples of seed of new Potatoes should not be encouraged; and if they were refused, probably many kinds which now fail to give satisfaction might prove to deserve the recommendation given to them by their raisers. I am sure, if other vegetable seeds were as badly proportioned as seed Potatoes generally are, they would be refused everywhere, and if we were more particular with our Potato seeds or sets, the results could not fail to be more satisfactory. So much for seed; now for its treatment. In this, I believe, mistakes are very frequently made, as in many cases seed tubers are never prepared for planting, but are put into the ground direct from the heap. When seed Potatoes are allowed to rest on the top of each other at this season and during the spring months, the young growths are encouraged to grow very long, and they frequently interlace the whole mass. Before planting can be done, they must all be moved, and in doing this the most of these growths are broken off, and those which remain are of no use, as a sprout on a Potato from 3 inches to 1 foot in length cannot be planted with advantage to the tuber at first or to the crop afterwards. The fact is, those elongated growths should never be allowed to form, and the seed tubers would be in a vastly superior condition if the shoots were only half an inch or so in length at planting time, and very robust in character. The tubers can then be moved without disturbing the growths, and they may be handled and planted with them on, when they prove a real advantage to the sure and early starting of the crop. I have tried a quarter with the abused sets, and another with those I mentioned last, and the crop was not only finer from these, but it also developed and retained a superior stamp of foliage, and all who wish to have good and paying crops of Potatoes must give attention to preparing the sets. It may be thought, if the growths become long and lanky now, they can be broken off and fresh ones of a more substantial description will form before they are planted or after they are in the ground, but the first growths are invariably the best, and these should be preserved and retained with the greatest care. The only way to secure robust growths is to spread the seed-tubers out in a single layer, and keep them cool and in

the light; so long as they are free from frost a low temperature will not check them, and they may be spread out in cool frames or any kind of house or shed. Early Potatoes should be taken in hand at once, and as these are planted they will make room for fresh batches of later sorts.

There is much satisfaction in planting plump, medium sized tubers bearing stumpy shoots which begin to grow freely and strongly as soon as they are put under the soil; but it is labour in vain to follow the rules of careful cultivation when the seed used is unworthy of the name. Those who have one or more acres to plant may think it would be a difficult matter to find room to make a layer of the seed; but those with acres of land to plant are generally pretty well provided with means of dealing with their seed-tubers properly, and where it is neglected it is not so much from a want of accommodation to spread out the tubers as a disinclination to do this, or an impression that it does not matter how the seed is treated, which is altogether a mistake. J. MURK.

KITCHEN GARDEN NOTES.

HERBS.—These should be well provided, for even if some are not asked for, the space which they take up is but little, and a well-arranged herb garden is always interesting. If possible, have all the kinds of herbs arranged together, and for convenience of gathering they should be near the vegetable shed. Now is a good time to overhaul the perennial kinds, and by division of roots increase the same, and throw away old roots of any kinds that are not needed. It is always desirable to have two small plots of Mint and Tarragon, the roots of one lot to be reserved for forcing in pots or boxes in the quantity required. A small box, 2 feet by 18 inches, will hold sufficient roots to produce a supply of Tarragon for the largest establishment, but several boxes of Mint, from four to six will not be too much, and the roots should be lifted at various times, say at intervals of three weeks or a month. The permanent small (very small of Tarragon) plots should now be freed of weeds and decayed stems, and afterwards a top-dressing of fine soil and manure about 3 inches thick be spread over the whole. When it is necessary to increase or renew the stock of either, prepare the soil by deep digging and manuring, and afterwards dibble in small portions of healthy roots about 4 inches apart over the entire space. Thyme, common, is in daily request, and should therefore be grown in quantity. If not too old, the roots will split up moderately well, but seedlings a year old are much to be preferred for renewal of plots. The plan we like best is to sow a pan, and raise the seeds in a cold frame, prick out in the open border about the middle of May, and from this stock our plot is now being renewed. The roots are planted at a foot by 18 inches apart. It is necessary to pinch out the points of the longest growths to induce a bushy, spreading growth. To have Lemon Thyme perfectly true, it must be increased either by division or cuttings. If more than three years old, the old roots do not split up nicely, and cuttings are much to be preferred. These we strike in sandy soil under hand-lights, arranged in any dry, sheltered corner. If put in about the end of September, the plants, as a rule, are ready to plant out now, though, if at all weakly, the planting had best be deferred till April, but the ground should be marked out whilst overhauling the others, so as to have all the varieties in one compact arrangement. Sage.—This is a non-essential, I know, but in all things, provided utility is not lessened, I like to study appearances, and therefore I go in for handsome bushes of Sage rather than lanky stems with only a few leaves at the top. To have such plants, seeds must be sown or cuttings put in at least once in two years. Seedlings give the least trouble, and we raise them the same as Thyme. Provided such a relay of plants is not at command, head back the old plants to within a few inches of the ground, point the ground between the roots and apply a rich top-dressing.

Of course, to maintain a present supply, part of the old plants must not be cut back till the others have made new shoots, then cut over the remainder, which operation may be done at any season. Balm, Hyssop, Angelica, and Pennyroyal are seldom required, except in very small quantities, and half a dozen roots of each are generally sufficient. Still, to prevent their extinction, it is necessary to occasionally lift and re-plant the healthiest offsets, and the present is a good time to do this. The foregoing are the whole of the kinds that I class, or advise, should be grown as perennials and in herb bed order, that is, in a plot by themselves. Of the annual section, Marjoram and Sweet Basil are the only kinds that are best sown under glass and planted out in May; Borage, Chervil, Dill, and Marigold should be sown in drills on a warm sunny border during the month of April; seed is cheap, therefore sow thick to ensure a plant, and thin out before the plants get crowded together.

JERUSALEM ARTICHOKE.—During the recent severe weather, when Broccoli, Brussels Sprouts, and other green vegetables could not be got, the great value of this excellent became conspicuous and was fully appreciated, being pronounced extra good. Though I venture no opinion as to whether they were or not, there is a double reason why such may have been the fact, the first being that the ground was better than we usually set apart for this good-natured tuber, and the next is they were dug up fresh as required for use, the ground being well protected with Bracken, not to mention the snow, of which we had sufficient to make us contented if we do not have any more for years. Generally we have lifted the crop in November or early in December and stored the same as Potatoes, but being so much hardier there is no doubt but that the right course to pursue is to leave them in the ground till there is danger of the tubers growing out. That time has now arrived, and we hope to be able to dig them up within the next few days, and having no other ground but that which they now occupy, we shall well manure and double dig it and replant with medium sized tubers. The rows will be 4 feet apart and the sets 2 feet apart in the row. We drill them in the same as Potatoes, and cover them with at least 6 inches of soil. The tubers for use will be stored in the Potato cellar and be covered over with straw to keep them from shrivelling.

CAULIFLOWERS.—Plants in handlights now have the fullest amount of air, the covers being left off altogether, except at night, when there are indications of frost. Those manifesting a tendency to button we have pulled out, and cleared decayed leaves from all; some required more space, therefore the spare plants have been lifted with all the soil adhering that it was possible to get without mutilating the roots of those that remain, which latter were at once earthed up with the siftings of the refuse soil from the potting-shed, and over this was spread a thick coating of soot. From plants wintered in frames the lights are now left entirely off, except during frost, and the Moss formed on the surface of the soil we have had scraped off with the fingers and the soil stirred with a pointed stick. We shall plant out in permanent position, at three different times, at intervals of about ten days, by way of getting successional supplies, and the first planting will be done about the middle of the present month. The plants from seeds sown in warmth a month ago are ready to prick out in frames, and this will be done at first opportunity. We have just made our first sowing in the open air on a warm sunny border, the sorts being Walcheren and Autumn Giant; the last-mentioned variety, though named Autumn, is about the best of summer Cauliflowers. By three sowings made from the present time to the beginning of April, a regular supply may be kept up, if the weather be open, well nigh till Christmas.

ASPARAGUS.—It is important that as soon as possible the plots should have whatever top dressing of soil or manure it is intended to apply, that the mixture may have time to get fully absorbed

in the soil before the roots start into active growth, at which period it is of greatest value. We use a mixture of soil, well-rotted manure, soot, and the ashes from the "smother" made by burning fruit-tree prunings, clippings from hedges, and the scraps of sticks raked up on the lawn and park; and over this is given a thick sprinkling of salt, which destroys grubs, prevents the growth of weeds, and is an excellent manure to boot. The old plan of ridging up the beds by digging out the soil from alleys is a senseless practice, exposing, as it does, a great portion of roots near the edges of the beds, and hinders the rainfall from being of most service to the roots by the ridged beds throwing it off into the alleys.

FORCING ASPARAGUS.—Given a good supply of roots and plenty of frames, leaves, and litter, there will be no difficulty in keeping up a constant supply of this delicious vegetable. We have all these except frames, and so we have to make shift as best we can. For the time being the floor of an early vinery is a most excellent substitute. The forcing bed is formed with hurdles, and good tree leaves is the heating medium. The plants are packed closely together in fine soil, the same as is done in frames, and the end of the matter is excellent produce, with, rather than otherwise, benefit to the Vines, as the moist heat generated by the leaves is most helpful to the expansion of the Vine buds, and the labour of syringing is not required; the humidity from the leaves and the occasional watering required by the Asparagus give off ample moisture. As the Vines advance to the flowering stage a fresh forcing bed will be formed by making up an ordinary hotbed, over which we shall erect a framework with hooped sticks, so as to tie over tarpauling, canvas, or mats as protection from bad weather. Our frames are all now in use for Potatoes, and the next planting of these will have to be made under temporary coverings in the same way. We have quite discontinued the unwieldy plan of forcing Seakale and Rhubarb on the ground where they have grown, as it is far more economical to lift the roots, and force them either in the Mushroom shed or in any other dark place. We put in roots in quantity desired at intervals of a week in respect of Seakale; but once in three weeks is sufficient for Rhubarb. Though it can hardly be called forcing, some may consider it so; therefore it is necessary for me to say that, for the very latest supply of Seakale, we cover the crowns over on the ground by heaping over them fine cinder ashes, and in this way get a supply a fortnight or more later than from the roots forced in pots or planted in the Mushroom shed.

GARDEN IN THE HOUSE.

PLANTS IN ROOMS.

THE following precautions should be observed, in order to prevent, as much as possible, any injury to large plants when removed from the plant house into the dwelling house: 1. Do not select any specimens in a growing condition, but choose those which have made their full growth, or such as are only commencing to push. The younger and more recently formed the leaves are, so much the more susceptible are they of being spoiled by being introduced into the atmosphere of a room. 2. Choose, if possible, the summer for introducing the specimens from the plant house into the dwelling house, as, the air being admitted into both these places at that season, the difference in the moisture of their respective atmospheres is not so considerable. 3. In removing plants into a warm room for the winter, do not select any which are growing in a low, moist plant house, but such as have been already hardened in the drier air of a high and dryish house. Care should be taken in this respect, not only with plants which are intended for permanent culture in the dwelling house, but also with those which are only placed there for temporary decoration. 4. Plants when first introduced into a room should be placed as near as possible to the window, with some shading from the direct rays of the sun in spring and summer. This protec-

tion will only be necessary for a short time after the introduction of the plants. 5. Plants removed from a moist plant house should be sprinkled with water every morning and evening for the first week, which will prevent the injury which would result from the excessive evaporation from the leaves. Anyone following these rules carefully will scarcely fail to successfully grow such plants as are commonly to be found in windows.

From some Cordylines which had been grown for years in a room, a selection was made of those kinds which are well known to be capable of enduring the open air in summer. These were placed in a glass-roofed balcony with open sides. Here, very soon indeed, they put forth a new and a stronger growth than they had made in the room. A specimen of *C. australis*, which had been already cultivated in the room for two years, and was covered with a mass of handsome overhanging leaves, especially distinguished itself by the development of leaves much larger, broader, and of a deeper green, just such as this species only produces when placed in the open air in summer. In the midst of this growth, these experiment plants were taken back into the room in autumn; but the results of moving them were very unfavourable. In the course of the following winter, *C. australis* lost all its old leaves and a portion of the new ones as well, and continued in a very sickly condition all through the winter, so that this fine specimen, which had kept its leaves for three years, was quite ruined by the experiment. *C. stricta*, which is one of the most durable plants for room-culture, and which, to be sure, on this account had, when brought back to the room, been placed in a rather dark part at a distance from the windows, gradually lost all its leaves and soon died.

That these injuries, which all the other plants which were thus experimented on likewise suffered in the loss of all their old leaves and a portion of the new ones, could only be attributed to their having been shifted from the room to the open air, was manifest enough from the fact that all the other specimens which passed the summer in the room continued to grow away uninjured, as in former years. The falling off of the old leaves were in this case entirely the result of the reaction of a summer's growth made under different conditions and influences, and which cost the plants the loss of the advantages of several years' acclimatization in the room. The partial loss of the leaves of the new growth resulted from this circumstance, that that growth was not quite completed when the plants were brought back into the room, where the higher temperature stimulated them to a further growth in the course of the winter. This part of the injury might have been prevented by removing the plants back to the room somewhat earlier in the season.

It is to be understood that all the preceding remarks on the acclimatization of plants in rooms are applicable only to the more important evergreen ornamental plants, whether intended for the temporary or permanent decoration of apartments. For the management of plants flowering in winter and spring, the rules just given will be useful, but for summer-flowering plants, such as Pelargoniums, the room is merely a winter shelter. What has been said respecting ornamental plants will apply equally to all flowering plants with evergreen foliage, which are wintered in ordinary dwelling-rooms with a temperature of from 45° to 60°. Such are Camellias, Indian Azaleas, and Ficuses, of which many amateurs purchase very handsome specimens at high prices. The buds with which these specimens are thickly covered excite lively expectations of future flowers. But it happens otherwise. In spite of the greatest care one bud after another drops off without opening, and with them all hope of flowers fall equally to the ground. Even when Camellias are grown in a plant-house, a change of position usually proves highly detrimental to the development of bloom. In a much greater degree is this the case when a Camellia, raised in a plant-house and covered with buds, is transferred to the dry air of a dwelling room. But the amateur who wishes to succeed with these plants should not allow himself to be discouraged by the unfavourable results which always follow for the first year after their removal, but should rather continue

his care of them. His perseverance will be rewarded by the success of growing Camellias in a dwelling-room to as fine specimens and as well furnished with flowers as it is possible to do in any plant-house. These plants, like the Evergreens, should make a new growth in the apartment to which they are removed, and, like them, should not be afterwards shifted to the open air.—H.

TREES AND SHRUBS.

W. GOLDRING.

THE SUGAR PINE.

(PINUS LAMBERTIANA)

IN California, that wonderland of trees, the vast forests of the Sierras consist mostly of Conifers of gigantic growth, and among these the Sugar Pine is one of the most remarkable. It holds the undisputed name of King of the Pines, for it is larger than any of its associates, towering

Full-sized scale and seeds of Sugar Pine.

above them all, and only excelled in height by those mighty giants, the Wellingtonia and the Redwood (*S. sempervirens*). The grandeur of the Conifers in Californian forests makes an impression on all travellers, and none more so than *P. Lambertiana*. In some localities Lambert's Pine may be seen upon every ridge and cañon of the Sierra Nevada, and it is the more

Cone and branch of *Pinus Lambertiana* (reduced).

noticeable because it is not found in large forests, like most of the others, but in scattered masses, the finest trees of it often standing out separated from all others (as shown in the accompanying woodcut), where it occupies an exposed ridge

along with a few saplings of Redwood. Some of these trees measure as much as 230 feet in height, and their ponderous boles are often 12 feet in diameter. These trees, thus exposed, have in many cases withstood the storms of centuries, and have thereby been rendered extremely picturesque. But it is its value for English gardens and plantations that we have now to consider; for, however noble a tree may be in its wild state, it is of little value here if not able to withstand our climate, or is not ornamental or good for timber. Writers on Conifers have been somewhat scant in their praise of the Sugar

and it is dense because the leaf-tufts feather all the branches, and so heavy are these tassels of foliage, that they droop somewhat after the manner of the Morinda Spruce. The colour of the foliage is a subdued bluish green, while the smooth bark of the stem and branches is of a rich cinnamon-brown. In the various arboretums where I have found large specimens, I could single them out from all the other Pines at a distance simply by the foliage, colour, and the singular drooping leaf tassels. The best trees I know are grown in a light soil with a gravelly subsoil, and in a position sheltered from cold

arranged in dense tassels, and of a glaucous grey tinge, particularly in their young state. The cones are of an enormous size, larger in fact than those of any other Pine. They commonly measure a foot in length, but often they are as much as 18 inches long by about 4 inches in diameter. When young they are of a deep green colour, purplish on the exposed side. They are produced singly at the slender pendent branches, and as they dangle at every breath of wind, they have a singular appearance. When ripe in autumn they are of a yellowish brown, the scales open and the winged seeds take flight, but the cones themselves remain on the tree till blown down by wind. These great cones have therefore two or three distinct phases of beauty—the green stage, the close stage, and the stage when the seeds have escaped and the cone scales reflex. Mr. Boverton Redwood, who has just returned from a visit to the Yosemite Valley, tells me that the singular appearance of these great cones on the old Sugar Pines is scarcely less impressive than their grandeur. He says that the ground beneath them is strewn with cones, one of which he brought me home. It measures just 17 inches in length by 5 inches in diameter. Every scale is empty, and as it is now hanging in a dry room the scales are beginning to reflex, which increases the diameter of the cone. Mr. Redwood says that the Sugar Pines were even more wonderful than the Sequoias, and no description can give an idea of their majestic size. *P. Lambertiana* was discovered in 1825 by Douglas, who introduced it to this country about the year 1827. It was named in compliment to the author of that noble work, the "Genus Pinus," and such a noble tree could not have been named after a worthier botanist. The range of the Sugar Pine extends throughout California and Oregon. It grows at elevations from 5000 feet to 7000 feet, but grows finest at about 5000 feet above sea level. Douglas stated that this Pine grows sparingly on low hills where the soil consists of pure sand. It covers wide areas about 100 miles from the ocean, and occurs most plentifully between the forty-third parallel on the north to as far south as the fortieth parallel.

Cone of Sugar Pine (*Pinus Lambertiana*) in sections (natural size).

Pine, but that it possesses great merit as an ornamental tree no one can deny who has seen a vigorous tree of it over 50 feet in height. I look upon it as a very fine Pine, distinct in growth from that of any other and different in colour. It grows rapidly, keeps perfectly erect, and retains its lower branches, which, together with all the others, have a downward tendency; on this account it is distinct from other Pines; even in youth the branches spring out quite horizontally, and as they acquire weight they begin to bend downwards. It is not a spreading tree at any period of growth,

winds, though there is nothing to fear in respect to its hardiness. Some, I know, think it too much like the common Weymouth Pine (*P. Strobus*) to render it of much value in ornamental planting, but this is a mistake, for though there is a resemblance, the Sugar Pine is a much denser tree and deeper in colour, besides the horizontal or downward tendency of branching is rarely seen in *P. Strobus*.

Lambert's Pine belongs to the *Strobus* or Weymouth Pine section, the species comprising which have five leaves in a sheath. The leaves are very slender, from 3 inches to 5 inches long,

***Pinus ponderosa*.**—The small number of specimens of this Pine that one meets with is surprising, for when from 30 feet to 50 feet in height there are few more imposing trees. The largest specimen of it with which I am acquainted is at Beaupart, near Hastings. When I saw it last it seemed to me to be one of the most distinct of all Conifers. As trees of it get old they unfortunately lose that dignified character which makes them so striking when younger; the branches become loose, and then they get wrenched off by wind and snow. It is not remarkable for great height, and if its name implies anything, it should be a useful timber tree.—J. C. C.

The Japanese Wych Hazel (*Hamamelis arborea*).—One of the first harbingers of spring flowers is this charming shrub, which opened its first blooms in Kew Gardens on the last day of January. A more beautiful winter shrub than this does not exist in gardens, and when seen in full splendor in the sunshine of a February day it may be described as a clod of gold. It is a singular-looking shrub, possessing at flowering time not a vestige of foliage, but each branch and twig is wreathed with golden blossoms. These are very curious and unflower-like. The petals are narrow and twisted about in an octopus-like way, while the centre is a deep red, so that each flower looks like a ruby set in shreds of gold. The growth of this shrub, or rather small tree, is erect and twiggy, and in summer is not remarkable for beauty, but for its winter bloom it is most precious. One can imagine the effect of a few specimens of it rising from a low mass of some Evergreen, and with an Evergreen background. It should always be planted in a get-at-able spot, so that its blossoms may

be seen and enjoyed. The North American Wych Hazel is not to be compared with this Japanese species for beauty.

BUTCHER'S BROOM.

ANYONE who has seen Butcher's Broom in a really happy condition, as, for instance, clothing the hillsides above Porto Fino, and to the south of Monte Telegrapho beyond Genoa, may well have wished to establish such an exquisitely lovely plant here at home. It is reckoned as a native British plant, but I only know one spot in England where it really fruits, and even there it is as different as possible in appearance from the glorious glossy green foliage sprinkled all over with lovely crimson-like berries the size of the biggest Marrow-fat Peas. Here in England it assumes a much closer habit, the leaflets are more crowded, and altogether it is of a much darker, gloomier hue; it always looks as if it felt the cold and had huddled itself together to keep warm, and even an undersized, stunted berry is indeed a *rara avis*. I have endeavoured to establish it under trees in my light, dry, sandy soil, but with very indifferent success. It lives, and that is all I can say for it. I lately noticed it growing very strongly into dense, thick, low bushes in the heavy clay of the weald of Kent, but so grown it is of forbidding aspect. I wonder if anyone has ever tried it planted out in a large conservatory or winter garden? It might do itself justice there. I have often seen it covered with berries for sale in the best flower shops in Paris, and two or three shoots of it mingled with a handful of *Laurus tinus* make a charming and lasting winter bouquet. From observing it both at home and abroad, I am convinced that though it is hardy here, and will struggle bravely against drought, it loves warmth and water and dislikes too heavy a shade. The only things I find to grow even tolerably under heavy shade, as of Oaks and Beeches, Scotch Firs and Ilexes, are *Rhododendron ponticum*, Box, and Holly. Even these will always under such conditions look enervated, but they do grow and cover the ground with greenery. —W. WILKES, *Shirley Vicarage*.

We have a large quantity of Butcher's Broom planted here (Northumberland) under an avenue of Lime trees, but it does not grow well, and never bears berries. All the points of the shoots die off, and even the tips of the leaves turn white. It is planted in a damp heavy soil. It is my opinion that it succeeds best in a dry position, for I have never seen it grow so well as it does in the south of Hampshire, where on a hot gravelly soil it grows wild and in enormous quantities, intermixed with common Furze and covered with bright red berries. —C. COLLINS.

The Water Oak (*Quercus aquatica*) is conspicuous among the Oaks in the Kew arboretum, as it is one of the few that have not shed their leaves; but it is not a good Evergreen, because the leaves get a rusty look by midwinter—at least in the neighbourhood of London. I should like to know if any readers in Devonshire or other warm parts of the coast could tell us if the Water Oak is a good Evergreen there. It is, no doubt, perfectly hardy, but unless it retains green foliage in winter, it is not of much value as an ornamental tree. —W. G.

The Pontic Daphne.—The beauty and value of this low spreading evergreen shrub is not recognised in lawn planting. A mass of it has, however, a grand effect; its foliage being of a much paler green than that of the turf, shows itself well at a distance. This Daphne is always dwarf and neat, and has an inclination to spread in all directions, so that if a dozen are planted in a mass, say about 10 feet or 12 feet across, a dense group will soon be the result. It is a good deal like the common Spurge or Wood Laurel, but the leaves are shorter and more oval in outline. The flowers produced in spring are also different, for while those of *D. Laureola* are borne in clusters of five, those of *D. pontica* are borne in pairs, are more yellow, and more sweetly-scented. There is a variety (*nubra*) with red flowers and another

with variegated leaves, but neither of these are common. The Pontic Daphne is a native of Asia Minor and Siberia, where it generally forms a dense undergrowth in woods, and rarely grows more than 5 feet high. It thrives in any soil, from almost a clay to an American peat bed. I saw and admired a most luxuriant mass of it the other day in a garden in the weald of Sussex, where the soil is very heavy, while on the poor, hungry soil at Kew it is quite as luxuriant. —W. G.

PINUS CEMBRA.

ALLOW me to add a few words to the excellent article which appeared in THE GARDEN (p. 104) upon our Swiss Pine. Even if that tree could at one time have been described as Swiss, and as being the prevailing tree in our Alps, such a description would now be quite incorrect. Our old books upon the Alps and Swiss history mention the fact that two or three centuries ago that tree was found everywhere upon the highest Alps. It was, above all others, the mountain tree, coming from the large plains of Siberia, and extending over all the mountains of Central Asia, the Alps, &c. The central parts of the Alps were covered with it, and it formed large and useful forests. Dr. Chust, in his "*Flora de la Suisse et ses Origines*," tells us that its numbers are now so much reduced, that the time can be foreseen when the glorious tree of our Alps will be a thing of the past. In the year 1822, Kasthofer wrote: "Still rarer than Larch-tree forests are Arolla forests; without the forester's help that tree can no more be preserved in our country, and it will soon be extinct in our populated valleys."

The Arole or Arolla has so many enemies, that it cannot survive if the foresters do not protect it. Human beings, birds of many kinds, squirrels, mice, and other animals are very fond of its seeds. Sheep and goats are fond of the young trees; but the most dangerous of all its enemies is man—man, the perfection of all the creatures in creation, who has the greatest interest in protecting the young trees, and in helping them to develop their branches; man, who is protected by the forests, and for whom these trees are treasures! During the past half-century the limits of the forests have decreased rapidly. It is sad indeed to think of the enormous diminution of our forests in all the Alpine regions lately. The shepherds for their milk industries, and the communes to extend their pasturages, cut down all these trees, which Nature has placed there to protect their districts. Large forests have been destroyed in order to get pasturages, and the wealth of the valley is gone with the woods. Arole trees can seldom be seen in forests; it is even rare to see pretty individual trees, and to see them in quantity it is necessary to go into districts like Arola, in the Val d'Arola, Valais, Hotel Weis-horn, in the Val d'Anniviers, over St. Luc, Valais, on the Riffel by Zermatt, in Grubben Thal, Valais, in the Engadine. Elsewhere they are rare and small. The tree grows very slowly. In a few minutes the woodcutter can undo the work that Nature took 1000 years to accomplish. I have seen in the Vallée de Nenday (Valais), in Civiez, large specimens of that tree cut down and rotting on the soil, the object of the destruction being the extension of the pasturages. And because our trees are becoming so rare, and our forests are disappearing rapidly, in spite of the excellent forest laws which Switzerland possesses, the Association pour la Protection des Plantes has added to her work "Protection of Forests," and has begun to cry as loudly as it can, "Our trees and forests in the highest regions are sacred; do not cut them down!" H. CORREVOX.

Guerra.

The Amur Ivy (*Hedera amurensis*).—This Ivy, to which an allusion was made the other day, has been grown at Kew for about four years. A large plant of it is growing on an open stump in the Ivy collection, and judging from its present appearance it is as hardy as any. The leaves are large and bold,

mostly heart-shaped, and are beautifully stained with brownish purple and overlaid by a network of green veins. It is to all appearance a first rate Ivy, distinct from all the rest, a fast grower, and perfectly hardy. —W. G.

Pinus flexilis.—This Rocky Mountain Pine is one of those scrubby-looking Pines about which I wrote the other day, but at the time I forgot to mention it. It is a distinct-looking little Pine in growth, much resembling others of the Scotch Fir race, but much darker in tint, and what is most remarkable, its branches are completely covered with needles, bottle-brush fashion. It is a fine little lawn tree, and I should always place it so that it would appear to be an off-shoot from a main mass of bigger Pines, or in a recess, either singly or a group of three or four plants placed within a few feet of each other. It is a native of the Sierra Nevada, and is one of the alpine trees of the Rocky Mountain region, where it grows to a large tree in some parts.

Magnolia Halleana.—This Magnolia is not so rare as some seem to imagine, but, pretty though it be, it certainly cannot claim to be the "finest of its tribe." It forms a low, much-branched shrub, and belongs to that section of the genus which blossoms before the leaves appear. The flowers, which are borne singly on the points of the shoots, measure from 3 inches to 4 inches in diameter, and are composed of a number of narrow strap-like petals, which, after being open for a short time, gradually reflex. They are pure white, but when in the bud-state the exterior is slightly suffused with pink. *Halleana* flowers about the same time, or a little later, than the Yulan (*M. conspicua*). Its leaves, which after a time make their appearance, are about 4 inches or 5 inches in length, and of rather a pale green hue. It is thoroughly hardy, at all events around London, as plants of it at Coombe Wood testify, yet it is not seen at its best except in some sheltered spot; where exposed the blooms are often injured by spring frosts. There is, however, one purpose for which this Magnolia when in blossom is well suited, and that is for the embellishment of the greenhouse or conservatory. It is very amenable to pot culture, and when protected by glass the blossoms are seen to advantage. It is now some half-dozen years since I first saw it in the temperate house at Kew, and I was then so struck with its beauty that I have since grown it under glass, and thus treated the delicious fragrance of its blossoms is more pronounced than in the open air. After blooming, we remove our plants to a frame, where they are gradually hardened off, and after a time plunged in the open ground. Under this treatment they set their blooms freely, and on the approach of winter they are replaced in the frame and in spring taken into the greenhouse. This Magnolia, like other members of the genus, is not an easy plant to propagate, for, though layers will strike root, their slow growth prevents such a mode of increase being extensively followed. It is generally grafted on *M. obovata*, which is mostly used as a stock for this section. *M. Halleana* is sometimes met with under the name of *M. stellata*.—T.

SHORT NOTES.—TREES AND SHRUBS.

Ivies.—Anyone interested in Ivies will be well repaid by a visit to the Royal Horticultural Society's gardens at Chiswick, where Mr. Barron has got together a very extensive collection of the different varieties, which, as the season advances, will be very interesting.

Picea bracteata.—This is perhaps less known than most Conifers, a circumstance to be regretted, as it is very distinct in appearance, and a capital subject for choice positions. Its appearance is lighter than that of many of the family to which it belongs, and if planted in good soil it should grow rapidly and attain a good height; seeing that it comes from California, it should, I think, prove hardy. —C. C.

Cotoneasters. *C. microphylla* allowed to trail freely over rockwork at Chiswick is now very conspicuous, being laden with beautiful coral berries. *Cotoneaster Hooker* growing in close proximity is bearing no fruit at all, and seems to have suffered very much from the late severe weather, the foliage looking as if it had been scorched.

Picea cephalonica.—This is not so extensively planted in parks and pleasure grounds as it deserves to be. It is a wonderfully fast-growing tree, and makes invariably a handsome specimen. Even in a young state the branches are so regularly set, that the contour of the tree is always pleasing. As a park tree it is of great value. Cattle do not like to touch it

on account of its sharp spines. Nevertheless, young specimens should not be left altogether unprotected.—J. C. C.

FRENCH GARDENING TOOLS.

A young English gardener, well up in short Grass mowing—a qualification, by the way, rather rare in the present age of mowing machines—would be considerably taken aback if required to make a clean-shaven lawn with the implement that is familiar to his French colleagues. To the eyes of an English gardener there can be nothing more awkward-looking than the French scythe. The blade, it is true, offers a tolerably close resemblance to that of English make, but here the similarity ends, for the handle is as straight as that of a prong, and there is but one grasp, which is placed about halfway down the handle. This is, of course, for the left hand; the right claps the upper portion of the handle just in the same way that one would take hold of a pitchfork or any similar straight-handled implement. To those used to the curved handle of our own scythe it would seem almost impossible to make good work with an implement of this description. It does do short Grass-mowing, however, very well indeed, and I am inclined to think that it has one advantage over scythes in use with us. The blade is very thin, and, contrary to what is the rule with French cutting implements, the scateur excepted, well tempered. In the hands of a good workman it will cut almost like a razor. In the matter of sharpening, however, the Frenchman goes to work in a manner that differs as much from that practised by us as the two implements vary in form. His first proceeding is to fix a piece of iron firmly in the ground, the top of which is wedge-shaped. He seats himself before this, and, laying the edge of the blade on the blunt edge of the iron, with a hammer taps it smartly from one end to the other; then, reversing the blade, he completes the first stage of sharpening. The second consists, as with us, in passing a "rubber" along both edges, but with this important difference that his rubber is flat-sided instead of being round, and that he never by any chance uses it dry. The rubber is kept in a horn containing water slung at the back of the workman, so that it is kept in a wet condition. It is easy to understand that in this way a finer edge can be obtained, for everyone knows that if we want to put a keen edge on a pruning knife we always sharpen on a moist stone. I should explain that the beating of the edge of the scythe is rendered imperative by the thinness of the material, which turns a little after being used some time. If a man is mowing all day long he will need to beat the edge of his scythe about twice. It will doubtless appear strange that such thin material should be employed in the manufacture of scythes, but there is good reason for this. Without a very keen cutting implement you cannot mow short Grass in France in the summer time. Owing to the great amount of dry heat, the Grass is so tough that I doubt if the most expert of English mowers could do much with it with our ordinary scythe. There is an almost entire absence of those heavy night dews that so frequently accompany very hot summer days in this country, and to which we owe much of our verdant freshness at that time of year, so that there is but little chance of taking advantage in the early morning of a moist condition of the Grass for mowing, as used to be done in English gardens before the mowing machine supplanted the scythe. Even at the present time the greater portion of the Grass in French provincial gardens is mowed, mowing machines being not nearly so much used as with us.

The French spade differs quite as much from the implement used in this country as the two scythes do. It has a long, straight handle like a prong, with no grasp at the end, and the blade, instead of being straight, is much wider at the top than at the bottom. It is certainly, to unaccustomed eyes, an awkward-looking tool, and a man using it has, at a little distance off, the appearance of pitch-forking the ground over. It does very well on light soils, but on heavy land I do

not see how it can do its work efficiently. The workman certainly has not the same power over it as with one of our make. The shovel has a handle of the same description, only not so long, but in factories and places where much fuel is burned the English shovel has for the most part taken the place of the French tool. There is one thing that would strike an English gardener as curious in French gardens, *i. e.*, the absence of the common hoe. If he were to ask for a hoe, he would be brought a ponderous-looking tool much resembling a mattock, only larger. This is a serviceable enough implement in its way, especially on heavy lands which become burnt and baked in summer, and on which in a dry time our common light hoe makes but little impression. Its principal use is to break up the surface to a depth of 2 inches or 3 inches, and it has its equivalent with us in the cultivator, which many English gardeners find under some circumstances a satisfactory substitute for the spade. The hoe proper of French gardens is the Dutch hoe, and for most kinds of light hoeing operations this is decidedly the best tool that could be used. I have often thought that the Dutch hoe is not so much used as it should be with us. In most large gardens it is valued, but in small ones one seldom sees it. It must be owned, however, that it is a tool for the thrifty gardener only. He who allows weeds to grow till they almost seed will want something different, but where the stich-in-time principle is in vogue, the Dutch hoe for all ordinary purposes is the best, and as regards expenditure of labour the most economical. With it a brisk workman will go over a lot of ground in a day, and working backwards, as one has to do, none of the weeds are trodden in to take a fresh lease of life, as is often the case with ordinary hoeing, and the whole surface soil operated on is left loose and friable.

With respect to watering pots, they are, as a friend of mine once said, "a caution." In form they are elegant, very much like some of the old-fashioned china jugs, but they are made of copper, and the opening at top, already small, is further diminished by a rim of from 1 inch to 2 inches in width, thus rendering the dipping of the water about as little easy as possible. The rose is not over large, and in a general way is not even made to be taken off. It forms an irremovable portion of the pot, which has the merit of simplicity, but which, when time is scarce and water is not so free from impurities as it should be, is apt, by being continually in a semi-choked condition, to cause much vexation. A more inconvenient garden implement I never used. The handle is of rolled copper, and runs from the rim of the can to about two-thirds of the way down, and from the opposite edge a bar connects it with the spout. One could understand that such an antiquated affair might linger in out-of-the-way country gardens, but it is difficult to understand that even in the Paris market gardens it should be about the only kind of watering-can in use. It would naturally be thought that to a quick-witted race of cultivators, such as the Paris market gardeners as a body are, the palpable defect of such a watering-can would many years ago have caused its total abolition where water-carrying forms the chief item in gardening work for a considerable portion of the year. It is probable, however, that some change has taken place in this respect within the last few years in the better ordered of the Paris market gardens. I know that a watering-can was invented by a Paris manufacturer which was specially designed for use in market gardens, and which it was thought would facilitate watering considerably. This was made in form between round and oval, with the opening placed as is the case with our own cans, but the handle, which was of rolled zinc, curves over the top of the can from the spout to about half-way down the back of it. In form this can certainly offers a contrast to, and has great advantages over, the old kind, the peculiar position of the handle being supposed to be the happy hit in its construction. This will be understood when I explain how much of the watering is done in French market gardens. Space there is very valuable, so that the alleys be-

tween the beds are of the narrowest, and on this account, and because work there is done at high pressure, the workman cannot make the ordinary double movement of setting down the can and then grasping it by the handle before using its contents. The cans are grasped, one in each hand, by the piece that connects the can with the spout, and being filled, they are carried in this way to where the watering is to be done. Then comes a bit of sleight-of-hand that requires considerable practice to become master of. As before mentioned, the cans are not set down, but the workman gives a short outward jerk of the wrist, which turns the can and brings the handle towards him. This he grasps, and goes to work at once, doing the same with the other can in its turn. This is termed by the French jumping the cans. It will readily be conceived that work of this description carried on for days together under a scorching sun is terribly exhausting. It will also be easily understood that the can above described would considerably reduce the toilsome character of the work, as, owing to the handle running from the spout to the back of the can, the hand has only to be slid backwards a little to bring the can into the right position for watering.

I may mention that a can identical with this was sent out some years ago by Messrs. Boulton & Paul under the name of the Battlesden can, but there has never been sufficient demand for it to warrant them keeping it in stock. I omitted to mention that an important feature of this can is that instead of the ordinary rose it is fitted with a long spout with a small opening, to which is affixed a contrivance for distributing the water in a thin wave-like spray. This spout gives the can a rather awkward-looking appearance, but having used it for a good many years, I am able to assert that it is very useful. With it one can cast a spray over a bed 6 feet wide, and it is not liable to choke up as the ordinary rose does. I have several of these cans in use, and would not like to be without them. With respect to pruning and budding knives, the French gardener has to put up with a very inferior article. It does not seem possible to get a good knife in France, and you can scarcely give a French gardener greater pleasure than in presenting him with one of real English make. What seems so strange is that the scateur is really an admirably tempered implement, and one would naturally think that there should be no more difficulty in making a good pruning-knife.

JOHN CORNHILL.

ORCHIDS.

W. H. GOWER.

HOULLETIAS.

THESE belong to a small family of distinct and handsome Orchids, which when not in flower much resemble some species of Stanhopea. The first-known kind was discovered on the Organ Mountains, near Rio Janeiro, but all the others are natives of the mountain forests of Columbia and New Grenada. Their flowers are doubly interesting on account of the peculiar structure of the lip and the pleasant aromatic fragrance which they emit. Houlettias grow best in pots, and just now is a good time to repot, or renew the soil about their roots. They thrive well side by side with *Odontoglossum crispum*, and require about the same treatment as that lovely cool Orchid. Houlettias produce their flowers in bold racemes, which are strikingly effective when contrasted with the snowy white blossoms of Princess of Wales *Odontoglossum*. Hitherto, however, from some unexplained reason, they have found more favour with Orchid growers on the other side of the Channel than with us. *H. Brocklehurstiana*, the species of Houlettia first grown in this country, has conical, strongly ribbed pseudo-bulbs, which bear a broad plaited deep green leaf; the scape, which is erect, bears

from six to twelve thick, fleshy flowers, each measuring some $3\frac{1}{2}$ inches across; their sepals and petals are deep rich brown, profusely spotted and transversely streaked with purplish brown. The ground colour of the lip is yellow, but it is almost hidden by lines and spots of brownish purple; the flowers are produced during winter, and have a delightful aromatic fragrance. *H. tigrina* has larger flowers than those of the species just described. The sepals and petals in this case are pale yellow, profusely mottled and variegated with rosy red. The lip, which is flat and spade-shaped in front, is white, freely dotted all over with rosy crimson, while the narrow stalk-like base is transversely streaked with red, and ornamented at each side with an erect, sickle-shaped horn, which is white, tipped with purple; and the large, arching column is white. It comes from Ocaña, and is usually found growing on the ground in forests there. *H. picta* is a native of the same country and is a similar plant, but the leaves have a longer stem; the scape, which is erect, like that of others, rises from the base of the mature pseudo-bulbs when the young growths push up; the flowers measure between 3 inches and 4 inches across; their sepals and petals, which are narrowest at the base, are rich brown, the basal half being yellow, chequered with transverse, oblong spots of cinnamon; the lip, which has a hastate lobe in front, is yellow or white, heavily streaked and spotted with blackish purple. *H. odoratissima*, which comes from Columbia, is somewhat less robust in habit of growth; the scape is about six-flowered; the sepals and petals are narrow, and dull red; the lip is white, with a curious, halberd-shaped middle lobe and a large, falcate, red, tooth-like process on each side; the column is large and white. The flowers of this species emit an agreeable odour, something like that of Violets. *H. antiocquensis* is considered to be a variety of the preceding, but differs from it in colour; the sepals and petals are broader, and rich reddish crimson in colour, but dull brown on the outside. *H. chrysantha*, which comes from New Grenada, has flowers of a rich golden yellow colour; the sepals and petals on the inside are profusely spotted with rich bright brown, and the lip is deep yellow, dotted with chocolate or crimson.

Lælia Turneri.—This is undoubtedly the richest and most deeply coloured form of all the varieties of *L. elegans*. It is both an autumn and winter bloomer, and is thus doubly valuable; although it has now been in cultivation some years, it would appear to be still scarce, judging from the fact that the "reserve price" of a moderate-sized plant in bloom is a hundred guineas. The flowers measure upwards of 6 inches across; the sepals and petals are deep purple tinged with rose; the lip is broad, spoon-shaped, and intense purplish magenta.

Odontoglossum Sanderianum.—This beautiful and distinct plant has vastly improved under cultivation, and may now be seen in bloom in abundance. On its first introduction it was supposed to be a natural hybrid between *O. nevadense* and *O. nevium*, a supposition which does not appear to be borne out by facts. The raceme is erect, dense, and many-flowered, and the individual flowers measure upwards of 2 inches across. The sepals and petals are yellow, streaked and spotted with crimson; the lip is white and the crest yellow, with a large triangular spot of velvety crimson in front, the middle lobe being pointed in front. It is an attractive winter-flowering plant.

Saccolabium cœleste.—Lovers of Orchids will be glad to know that Mr. Shuttleworth, of Clapham, has recently received a consignment of this rare and beautiful plant. It appears from these imported plants that it flowers and seeds most freely in its native country. It has somewhat the habit of *S. curvifolium*, but the leaves are broader, nor are they of that yellowish hue which is so marked a feature in

that species, but rich deep green. The raceme is erect, nearly a foot long, and densely flowered. We believe it has as yet only been flowered in this country by Sir Trevor Lawrence. The lip is amethyst, the sepals and petals being also tipped with the same colour. The rarity of such colours amongst Orchids must assuredly render this plant popular.

ORCHID CULTURE.

"W." puts the question, "Does Orchid growing pay?" And then, after drawing a gloomy picture of the plants and the meagreness of their flowering, arrives at the conclusion that not only does the cultivation of Orchids not pay, but that they are not desirable plants to grow. Now, taking all that may be fairly urged in their favour, including the singularity and

Sugar Pine on an exposed ridge. (See p. 152.)

elegance of their flowers, their chaste and beautiful colours and enduring properties, there is not likely to be any falling off in the estimation in which Orchids are held by any but a few who are prejudiced against them. As to whether their cultivation in private establishments pays or not, according to the ordinary acceptance of the term, there can be no question that when well selected the balance will be much in their favour as compared with most other plants. And this I hold to be the only way in which the question can be put. What of the soft-wooded quick-growing plants that now principally fill the cool and warm plant houses of the present day—the Begonias,

Pelargoniums, Chrysanthemums, Cinerarias, Cyclamens, Fuchsias, Ferns, fine-leaved and flowering stove plants? Do growers of these expect to get anything worth naming for them if they should happen to give up their cultivation? If they do, they will find out their mistake. Yet the plants in question cost as much for house room, fuel, and attention as Orchids if grown in a way to give satisfaction to the owner or credit to the gardener. "W.'s" comments might have held good if the extravagant prices that Orchids used to fetch were still the rule, when most of the desirable kinds realised more pounds than they now do shillings, and when they were killed by thousands through the barbarous treatment to which they were subjected.

From opportunities which I have had of seeing great numbers of collections, large and small, throughout the country, I can say, emphatically, that the assertion that Orchids are unsatisfactory is groundless. Places may occasionally be met with in which Orchids, in common with other things, are in the condition described by "W.," but those who know anything about plant culture have little difficulty in defining the reason why. And it is not on exceptional cases of bad management that an estimate of any value can be formed. What Mr. Crawshaw says about individual plants in private collections realising two or three hundred times more than they originally cost is simply in accordance with my own experience, and that of others who have had to do with Orchids, and who know the right way of obtaining the plants which they grow. But leaving lucky hits of this kind out of the calculation, and taking up the more reliable evidence forthcoming from the cultivation of these plants in greater or less quantities, I could name many instances where, after being grown for a number of years, they realised a handsome return when part or the whole came to be disposed of. One case in particular, where some two hundred pounds were spent in a selection of cool Orchids, newly imported plants, amongst which were a number of *Odontoglossums*, the collection was kept intact for several years, after which six hundred pounds' worth were sold, leaving quite as many more that would to day fetch another six hundred.

One cause through which many who have gone largely into the cultivation of Orchids ultimately find that more or less of their plants are worth less than they should have been is that insufficient knowledge was brought to bear on the purchases made at the commencement before they had learned to keep clear of the weedings out from the collections of others who have had experience, and have learnt the difference between good and inferior varieties. In this way many of those who form collections pay for their learning. Another cause which works in the same direction with those who are enthusiastic, and who can see more in rarity than it is worth, is that they give extravagant prices for any species that is new and supposed to be limited to a few examples, when somehow or other it oftener than not turns out that someone interested knows where the supposed rarities can be dropped on by hundreds or thousands. I well recollect seeing a single imported piece of *Pendrobium Wardianum* knocked down at a sale in London for 100 guineas. It was not long after that a wheel-barrowful would not have fetched so much money, and I could name scores of species that have afforded a like evidence of the mistake of giving extravagant prices for new Orchids, without taking into account the probability of there not long being any scarcity of them.

"W." says that Orchid culture is on the wane, giving as his authority for arriving at this remarkable conclusion the evidence of trade-growers who tell him that such is the case. The assertion is a fair example of the mistakes people fall into when their opinions have no better foundation than the one-sided statements they happen to hear. Those who are acquainted with facts connected with the subject will easily detect where "W." has been led astray by what he has been told. There was a time when Orchids which reached the hands of growers came wholly through the trade, except now and then when a private collection came to the hammer. Now all this is changed; in proof of which it is only necessary to point to the thousands of newly-imported plants, and of plants

that are making their first growth after being imported, that almost every week in the year are sold by auction in London, to say nothing of quantities of a like character that are similarly disposed of in large provincial towns, and which collectively in all probability represent three-fourths of the whole number that pass into private hands. The simple truth is that Orchids, consisting of many well-proved, sterling species, now cost little, if any, more than young plants of ordinary stove and greenhouse stock, the result of which—as anyone knows who moves about sufficiently to be able to form an opinion—is that in half the gardens of any importance throughout the country Orchids in considerable numbers are grown, and as often as not are better grown than anything else.

T. B.

Trichopilia laxa is not one of the common species, and is not mentioned in Williams' Manual. It is different from the rest, and reminds one more of a *Pilumna* than a *Trichopilia*. It bears a pendulous flower-spike about a foot long with the blossoms loosely arranged, hence the name. They are some 2 inches across with narrow sepals, petals and lip, and entirely ivory-white. In flower at Kew.

Sophrontis violacea is quite a little gem among Orchids, and the colour of its small flowers being so different from that of most Orchids makes it the more valuable. It is altogether smaller than its relative, *S. grandiflora*, and its flowers, each about 1 inch across, are borne singly on the top of the tiny oval bulbs. The colour is a bright violet, deeper in some forms than in others. It lasts a long time in bloom—several weeks, in fact. Being a native of the Organ Mountains, it thrives best in a cool moist house. Now in flower at Kew.

Oncidium falcipetalum.—It is well to record the name of this new, or, at least, rare *Oncidium*, as some growers may wonder what it is like. It is one of that puzzling section to which *O. superbium* and *macranthum* belong. In growth it much resembles *O. macranthum*, the bulbs being long and thin, and disposed in an irregular way. The flowers are nearly as large as those of *macranthum* and of similar shape, the broad rounded sepals are of a bronzy yellow, the side petals are curiously crimped, and are reddish yellow barred with yellow. It may be seen in bloom at Kew now.

Dendrobium luteolum.—There is something very pleasing about this *Dendrobe*, although there is no bright colour in its flowers. It is one of the few *Dendrobes* that retain their foliage throughout the year, and the cheerful green leaves of *D. luteolum* harmonise beautifully with the flowers, which are of a soft primrose-yellow. The flowers are from 1 inch to 2 inches across, and in well-grown plants they completely wreath the leafy stems, and as these naturally droop, they are most elegant. It is one of the very best Orchids that can be grown by those who do not want to make a speciality of Orchids, as it may be grown to perfection in a hanging basket in an ordinary stove-house. There was a specimen of it shown at South Kensington on Tuesday, but this did not show the elegant growth of the plant, and therefore was not certificated.

SOCIETIES.

ROYAL HORTICULTURAL.

FEBRUARY 8.

THIS, the opening spring show at South Kensington, was unusually bright considering the severe weather lately experienced. It was held in the East Crush Room of the Royal Albert Hall, an unsuitable position for displaying the rich and varied colours of many of the exhibits, notably those of the beautiful collection of *Primulas* staged by Messrs. Carter, High Holborn. A great many novelties were exhibited, amongst which the following were awarded first-class certificates:—

LYCASTE PLANA MEASUREIANA.—A beautiful variety, the labellum of which is white spotted with crimson; the petals and sepals are nut-brown. It is sweetly scented, and undoubtedly a fine variety. Shown by Mr. B. S. Williams.

ODONTOGLOSSUM CRISPUM LEOPARDINUM.—A beautifully spotted variety, the flowers of which are large and of good substance. Exhibited by Mr. H. M. Pollett, The Firs, Bickley.

PACHYSTOMA THOMSONIANUM.—A very pretty dwarf plant, bearing from one to three flowers from the base of the bulb. The lip is white marked with reddish purple streaks; the sepals and petals are pure white. Shown by Mr. Vanner.

PRIMULA SINENSIS SNOWFLAKE.—A Fern-leaved variety producing large trusses of pure white flowers of great substance. Shown by Messrs. Veitch.

PRIMULA WHITE PERFECTION.—This is, without doubt, a grand acquisition, producing strong and well-formed trusses of massive white flowers. From Messrs. Cannell.

PRIMULA PURITY.—The flowers of this are pure white, large and fine. Shown by Mr. James, Farnham Royal.

PRIMULA BRIGHTNESS.—A semi-double variety with bright red flowers and of fine habit. Shown by Mr. James.

Among miscellaneous exhibits, special mention must be made of the collection of *Primulas* from Messrs. Carter, to which a silver Banksian medal was awarded. It consisted of over 500 plants in nineteen varieties, and, taken as a whole, was very interesting. Conspicuous among them we noted *Elaine*, a variety with pure white flowers. This kind was also shown in the Fern-leaved section, the examples in both cases being good. Fern-leaved Red, flowers large and fine; White, a large, bold, white flower; Blue, flowers mauve, of fair size; Prince of Wales, flowers semi-double, rosy crimson; Fern-leaved White, trusses stout and dwarf, flowers of good form, slightly flushed; Gem, very similar to a variety named *Lilacina*; Vermilion, an effective and beautiful bright red; and Venus, white, spotted with crimson. Mr. W. Bull put up a very interesting group of Orchids, interspersed with Palms and similar plants. This collection was very noteworthy, as it contained such a variety of the *Cattleya Trianae* section in different shades of colour. These of themselves made quite a display. Amongst other noteworthy subjects we observed the chaste and beautiful *Lycaste Skinneri alba*; *Cattleya amethystoglossa marmorata*, carrying a beautiful spike; *Dendrobium luteolum*, well flowered; the pretty *Coleogyne cristata* and its variety *Lemoniana*; *Dendrobium speciosum* Hilli, *Cypripedium Haynaldianum*, and many other varieties. A silver-gilt medal was deservedly awarded. Mr. R. J. Measures, Camberwell, exhibited a collection of *Cypripediums*, including *Sallieri*, a hybrid between *villosum* and *insigne*; *insigne grande*, of the *Maulei* section, but having brighter violet markings, and more white than the original variety; *chloroneurum*, a cross between *venustum* and *villosum*; *insigne Richardi*, one of the finest of this section we have seen, the petals being distinctly marked with large violet blotches and lines; *Williamsi*, the result of a cross between *venustum* and *Harrisianum*, also *Odontoglossum maculatum* Donianum with forty-two flowers, very fine. Mr. B. S. Williams also exhibited *Dendrobium Fytchianum roseum*, a rose-shaded variety of this well-known Orchid, and *Primula Magenta Queen*. Mr. H. M. Pollett sent *Odontoglossum Marriottianum*, flower large, but of little merit. Mr. Tautz, Goldhawk Road, Shepherd's Bush, showed a variety of *Cypripedium* Boxalli named *atratum*. A plant of *Dendrobium Vannerianum* was shown by Mr. W. Vanner. Mr. F. A. Philbrick, Oldfields Bickley, sent a finely flowered *Phalenopsis Stuartiana*, also *Saccolabium bellinum*, and a plant bearing a spike of seven blooms of the beautiful *Phalenopsis casta*. Mr. A. Balstone, Timperley, near Manchester, sent a fine spike of *Calanthe nivalis*. Messrs. Masemel Bros., Ghent, Belgium, sent cut blooms of varieties of *Odontoglossums*. Mr. T. S. Ware made an imposing display with *Narcissi* and spring-flowering plants, amongst which were large masses of *Helleborus niger maximus*, *Helleborus colchicus*, *Crocus Imperati*, *Crocus nivalis*, very dwarf and pretty; *Chionodoxa Luciliae*, chaste and showy; *Lachenalia pendula* and *Nelsoni*. *Freesia refracta alba*, *Iris Histrio*, and *Primula floribunda* were also included in this group. Cut flowers of *Chrysanthemum* Mrs. C. Carey, showing what a useful late

variety this is, were also shown. A silver-gilt Banksian medal was deservedly awarded to this interesting and pretty group. Messrs. Collins Bros. and Gabriel contributed *Narcissi* and early-flowering spring plants, for which a silver Banksian medal was awarded. Messrs. Barr and Son also showed a very fine group of *Narcissi*, &c., for which a silver Banksian medal was awarded. Mr. Allan, The Gardens, Gunton Park, Norwich, sent two baskets containing profusely-flowered examples of *Violets Comte de Brazza*, *Marie Louise*, and *Neapolitan*. The white variety was especially noteworthy. A cultural commendation was awarded. Messrs. Paul and Son exhibited *Iris Histrio* from out of doors; its flowers are rich bluish purple, the petals spotted with very dark purple. Mr. W. B. Hartland, Cork, sent fine blooms from the open ground of *Narcissus Irish King*. Mr. W. Gordon, Twickenham, exhibited two unnamed varieties of *Camellia*. Mr. James showed two Chinese *Primulas* named *Mary James*, with large lilac flowers, and Faust, purple-flowered, also cut blooms of his strain of *Cinerarias*.

The labours of the fruit committee were very light on this occasion. Messrs. Saltmarsh and Son, Chelmsford, had a seedling Apple named *Lord of the Manor*, which the committee desired to see again. Mr. Ross, Welford Park Gardens, sent a seedling Apple named *Lady Alice Eyre*. Messrs. Rivers and Son, Sawbridgeworth, had several varieties of Apples, for which a vote of thanks was awarded. Mr. W. Taylor, Hampton, showed specimens of his fruit trees in pots, and also trained specimens. Mr. Troughton, Preston, sent *Cucumber Troughton's Prolific*, which was similar to *Rollisson's Telegraph*.

The Permanent Enamel Company, Pelly Road, Plaistow, exhibited samples of their imperishable plant labels on which the names of the various subjects are produced in conspicuous white letters on a blue ground. The committee considered them superior to any already in use of a similar make.

The annual general meeting was held in the East Crush Room of the Royal Albert Hall at 3 p.m., the president, Sir Trevor Lawrence, Bart., M.P., in the chair. He called the attention of the Fellows to the various paragraphs in the report, from which an extract was given in THE GARDEN last week, more especially to that, referring to the future of the society. He said that the council had been in correspondence with the corporation of the Royal Albert Hall as to the use of the conservatory for the purpose of holding meetings, shows, &c., but, he was sorry to say, without result. Mr. Harry Veitch said he could not see why the society should not have a freehold of its own, and that if this was secured, funds would soon be forthcoming to erect buildings, and thus form a permanent home for the society. He moved that a sub-committee of five or more be selected to co-operate with the council as to this matter—a suggestion which was adopted. A cordial vote of thanks to the chairman then terminated the proceedings.

Vine insects (G. Wood).—The insects found in your viney are small beetles, belonging to the genus *Aphodius*. They are quite harmless to vegetation. They bury small pellets of manure in which they lay their eggs; the grubs when hatched feed on the manure, with which they are surrounded. These insects were probably introduced into your viney when in the chrysalis or grub state with some manure, and the beetles have since been developed. When found on the wall plate they were probably trying to make their escape.—G. S. S.

Gooseberry caterpillars.—The suggestion as to the use of alum water for the destruction of these pests is so good a one, that I have made special note of it for the benefit of the market growers in this locality, who chiefly resort to the free use of soot, a dirty and noxious compound, and specially so when used on bushes bearing fruit. I assume that the alum produces no injurious effects upon the foliage of the bushes.—A. D.

Potatoes (E. B.).—If the ground is fairly rich do not manure. A sprinkling of bone dust put in the lines when the sets are planted would, however, be beneficial.

Names of plants.—C. T. J. — 1. *Asplenium lanceolatum*; 2. *Asplenium Belangeri*; 3. *Polystichum coriaceum*; 4. *Clematis cirrhosa*.—T. H. — 1. *Odontoglossum Ruckmannianum*; 2. *O. Rossi majus*; 3. *O. Cervantesi deora*; 4. *Masdevallia ignea*.—J. H. G. — 1. *Dendrobium japonicum*; 2. *Cattleya Percivaliana*; 3. *Pteris comans*.—C. de G. — *Galanthus nivalis procerus*.—J. C. L. — 1. *Helleborus niger angustifolius*; 2. *Helleborus colchicus*.

WOODS & FORESTS.

THE TABLE MOUNTAIN PINE.

(PINUS PUNGENS.)

Is looking over a recently purchased copy of London's "Arboretum," I was struck by the similarity between an illustration there given of this Pine, and a specimen of the same tree growing at Penrhyn. What renders this Pine so distinct and conspicuous from the generality of its fellows is the large yellowish brown cones which are arranged in whorls around the stem and branches, and which, from the scales being sharply hooked, have a very unusual as well as formidable appearance. The whole contour of the tree is irregularly spreading, with pale yellowish green leaves, $2\frac{1}{2}$ inches long, and placed rather thickly on the branches; cones without footstalks, nearly 4 inches long by 3 inches diameter at the base, and gradually tapering to a sharp point. They are produced in great numbers on the stem and branches, I having counted as many as a score in one mass, and all point horizontally. Unlike the generality of cones, those of the tree in question are remarkably persistent, and remain on the tree for many years. To remove them is a task that is by no means easily accomplished, for, as they are thickly covered with sharp spines, and grow closely together on the stem, they almost defy one to remove them without sustaining serious injury to the hands; indeed, I was obliged when procuring specimens for the Forestry exhibition, to have them removed by the back of a hatchet.

Although introduced to this country early in the present century (1804), few, indeed, are the specimens of this remarkably distinct Conifer to be seen, and I cannot remember having found any allusion to it in our forestry papers; but this may to a great extent be accounted for by its almost valueless character whether as an ornamental or timber-producing tree. As a Pine of very unusual appearance it is, however, well worthy of attention, and should certainly find a place in every well-arranged pinetum, and, being perfectly hardy and of free growth, it is well fitted for even high-lying grounds. Our largest specimen was, unfortunately, blown over a few years ago, and sorry was I, for a more distinct and attractive Conifer certainly could not be found amongst the fine collection of those amassed by the late Dr. Hamilton Roberts, of Brynmeing. Judging from its growth at Penrhyn, I should say give *Pinus pungens* an airy situation amongst rocky debris, and let the soil be of a free, half leamy, half peaty nature, and it will succeed well enough. Although cones were produced in great abundance here, I fancy that male flowers were wanting, for no seedlings ever appeared, although a good deal of trouble was expended not only in extracting them, but in sowing in what was considered a congenial soil and situation.

The popular name of the tree is derived from that high peak of the Alleghanies—Table Mountain—on which it is found, and it may perhaps be interesting to state that this is the only range on which, so far as I am at present aware, it has been discovered.

As regards the quality of the timber of so rare a tree, we cannot, and must not, speak with anything approaching confidence, for although the specimen above referred to as blown over was, no doubt, the largest of its kind in this country, still the giving of an opinion from the wood of one solitary specimen would be rather hazardous. "It was hard to cut, and still harder to remove

the branches from the stem when felled," at least so said the woodman. A. D. WEBSTER.

Penrhyn Castle, North Wales.

Firewood.—This subject is well worthy of consideration at present when so much fallen timber is lying about. The question is, Will it pay? In certain districts where there is a difficulty in getting coal, firewood comes to be a necessity, but in districts where coal is plentiful, it is very questionable if there is any advantage from burning wood. The chief points on which further information is required are: What will it cost to prepare a ton of firewood? What size should the blocks be for general use? Should the wood be sawn, or split with the axe? What is the best kind of wood and the best kind of grate for burning firewood?—BEECH.

Pinus rigida.—London's illustrations of this distinct and, to me, pretty Pine, as reproduced in THE GARDEN of last week, hardly do the tree justice, and I think most persons who have even a few specimens in their grounds will feel inclined to say likewise. The cone is much longer and differently shaped to any I have seen, while the wing of the seed is small and narrow, hardly half the width of that represented. To see this Pine from day to day is how one will best get acquainted with its peculiarities, for a good deal of the knowledge derived from books regarding it is faulty in the extreme. We were always under the impression that *Pinus rigida* avoids the seacoast, but we are now told that it is valuable for planting in such situations. We have known it to be killed outright in maritime places, and would be glad to know what is the composition of the soil where it succeeds so well as a seacoast tree.—A. D. WEBSTER.

Marketing home-grown timber.—The idea of selling direct to the consumer is a taking one no doubt, but before it can be carried out considerable changes in wood management would have to be effected in all that relates to the felling, cutting up, and storing of the timber. The timber merchants have it in their own hands at present, and they can afford so many facilities to buyers that it is doubtful if the producer could compete with them successfully. On large estates, with the aid of a sawmill, much of the home-grown timber can be and is used for common purposes, and in the busier centres of industry where coal and iron are worked large quantities are disposed of to the consumer, but these may be said to be exceptions. In the out-of-the-way parts of the country, where timber is often most abundant, the cost of transport comes in to reduce the profits. The only apparent course open to the producer is to use the timber at home as far as possible, and dispose of it to local tradesmen and manufacturers, but he would first have to cut it into convenient logs in many cases, as the timber dealer does, and that would involve changes in our present system of management. At present it is a suggestive fact that when owners of extensive plantations have to build a mansion or effect any repairs therein not a chip of their own timber is employed for any purpose. Some firm in London gets the contract, and imports every foot of timber which he requires at a great cost to the employer. I could name estates on which large tracts of forest exist where the window frames and wood-work for workmen's cottages and the like are procured from a wood merchant who imports them ready made from Germany. Not long since a gentleman wishing to renew the Oak wainscoting in his house and effect other changes would not use a bit of his own timber, although he had some acres of good Oak, from which a "fall" is cut and disposed of to the timber merchant annually. The fact is, estates are without the appliances to convert the rough timber into marketable form, and owners will have to combine in the disposal of their crops if they wish to sell to the consumer. In former times home-grown timber was almost exclusively employed in house building, as the joints and fittings in every old house testify.—J. T.

Timber of the deciduous Cypress.—The timber of this tree is very durable, even under water, and is finely grained and of a reddish colour. A peculiar property of the wood is its adaptability to

split straight, so as to serve for planks without the use of a saw. To cultivate this tree successfully it must have good, rich soil, a well sheltered situation, and abundance of moisture, not stagnant, which is probably the reason why a sandstone district is preferred, a chalk soil being too dry, and a clay subsoil defective in drainage. The tree is readily propagated from cuttings or seeds, of which latter a good supply is regularly imported from America. It is never planted for profit, but only as an ornamental tree for park or lawn decoration.—W.

SEASONABLE WORK.

If not already done, finish planting now, and renovate old hedges before the buds begin to burst. Young Oak trees two years transplanted into nursery lines should be planted out in the forest where they are to remain, as such plants always succeed better than those of a larger size, and if well handled at the time of planting seldom require to be cut back. In cases, however, where the soil is of a poor thin description resting upon hard till, such ought to be trenched from 16 inches to 18 inches deep previous to planting; and as I have always found it best to have this sort of work done by contract, I may state that I have had it thoroughly done at the rate of £8 per imperial acre.

Felling heavy timber and thinning young plantations will still demand attention when hands can be spared, and in doing so remove such trees as are of an unhealthy appearance, although it may sometimes happen that such are not the trees that could be wished to be cut with regard to distance and regularity, yet such a system of management is the best for the ultimate welfare of the plantation. As the work proceeds, collect and remove all branches and rubbish, which if left would only be a harbour for insects and vermin; clean out drains and repair the fences if necessary, so that everything may be efficient, and have at the same time a clean, tidy appearance.

See that all newly-planted trees and shrubs on lawns are properly fenced and tied to prevent wind-waving, and apply a good mulching round the roots, which will be useful in retaining heat and preventing too sudden evaporation in spring, and on exposed situations I have found it to be highly beneficial to erect a screen of branches to break the force of the wind till such time as the plants take to the soil, and get established. Young specimen plants of ornamental trees and shrubs will require to be protected with wire netting. In erecting the fence round the plant the netting is kept on the surface (not sunk, otherwise it could not be removed without tearing up and destroying the roots) and fastened to small upright posts, and made fast to the ground by small hooked pegs. The fence may be placed at such a distance from the plant as will be convenient for a person to weed and dress the surface from the outside of the cage, as this is highly beneficial for the growth and healthy development of the plants in early life, and should always be well attended to in the growing season. I have occasionally found that a young rabbit, about the size of a rat, could squeeze itself through a 2-inch mesh, but they rarely do any harm, as they are never at rest until they get out again to their freedom.

In many cases, where valuable ornamental trees have been partly blown down, such may be pulled up to their former position and properly tied, and by covering the roots with fresh soil mixed with leaf-mould to encourage the formation of young roots, they will soon re-establish themselves and be saved. When the weather is open and the ground sufficiently dry, tree seeds may be sown on well-prepared ground in the nursery, such as Elm, Sycamore, Ash, Beech, &c. Put in cuttings of trees and shrubs not usually propagated by seeds, such as Willows, Poplars, Elder, Privet, and Sea Buckthorn.

Examine all the principal drains in flat peat bog plantations, to see that they are in proper working order, as from the small declivity of such drains they are easily choked up and rendered useless. Repair bog roads where necessary by applying a good coat of Larch or Fir branches, which answer the purpose admirably.

"This is an Art
Which does mend Nature: change it rather; but
THE ART ITSELF IS NATURE."—*Shakespeare.*

ROSE GARDEN.

T. W. GIRDLESTONE.

GROUPING ROSES.

THE practice, once so general in large gardens, of planting only single examples of a great number of varieties of Roses is less prevalent than it used to be; but there is still room, even in many so-called roseries, for much bolder treatment in the matter of planting in order to take full advantage of the great capabilities of the Rose for making our gardens gay. A bed of Roses, in which each plant is different from the other, cannot produce a very striking or harmonious effect; the plants will all be of different heights and sizes, and their various flowers will never be expanded at the same time; as the number of varieties that have brilliant flowers and also a good constitution is not unlimited, there must be a considerable admixture of dull colours to mar the effect of those that are bright and pure; while if, as is generally the case in such Rose beds, the trees have in the first instance all been studiously planted at equal distances, there will, according to the varying vigour of the different individuals, be here a crowd and there wide gaps. If, on the other hand, six or more plants of a variety be grouped together, a brilliant display will be readily obtained. From a knowledge of the habit of the particular Rose, the trees may be planted at such distances apart as to ensure the furnishing of the bed without undue crowding; the flowers on all the plants in each group will expand practically simultaneously; and as by such arrangement fewer sorts will be required, only the very best and brightest varieties need be grown. In large beds irregular groups of from six to thirty plants of each variety make a striking display of colour, whether seen from close at hand or at a distance; but if the Roses are grown in numerous adjacent beds of less size and various forms, it is a good plan to fill each bed with plants of one variety.

Neatly all classes of Roses furnish some varieties that are first-rate subjects for massing in this way, whether Teas, Hybrid Perpetuals, summer or other Roses, and as east winds and frost have again stopped planting operations, already so long suspended during the severe weather, it may still not be too late in the season to suggest some of the most desirable for the purpose.

Beginning with the Hybrid Perpetuals as the most generally cultivated class of Roses, the best six sorts for the south of England are probably Alfred K. Williams, Baroness Rothschild, Charles Lefebvre, La France, Madame Gabriel Luizet, and Violette Bouyer. The first-named is unimpeachable on the score of colour and form, even the small blooms often produced on twiggy growth or late side shoots being as well finished as the finer flowers from the stout wood; the plant blossoms early and abundantly, is sufficiently vigorous, the flowers open well in sunny weather or in dull, and are developed in the autumn more freely than those of almost any other variety in the class. In fact, in Alfred K. Williams the late M. Schwartz may be said to have sent out a Rose more nearly answering to the French raisers' favourite description of "possessing all the merits" than any other Hybrid Perpetual.

Baroness Rothschild also is a very free autumnal variety, and its value is enhanced by the fact that the stoniness of its petals enables its charmingly fresh-tinted flowers to endure exposure to a considerable amount of rain and wet without loss of colour. The stiff, upright habit of growth of this variety causes the plant to occupy but small space, and the plants may safely be planted not more than 1½ feet apart. It would be unreasonable to object, on account of its want of fragrance, to a Rose selected for the purpose of making the garden gay rather than for supplying cut flowers; but if the Baroness's one reproach of scentlessness be regarded as a fatal objection, a worthy substitute may be found in Prince Arthur, the beautiful dark crimson form of General Jacqueminot, introduced by Mr. Benjamin Cant in 1875. Charles Lefebvre, as the catalogues have it, "so well known as hardly to need description," when at its best is still unsurpassed in its colour, and its happy propensity for not unfrequently producing late in autumn, flowers hardly less perfect in form and tint than those expanded in summer is worthy of note. La France, too, the freest flowering of all autumnal Roses except the pure Teas, truest of Hybrid Perpetuals as the most fragrant, hardly betraying when well cultivated the lurking lilac tint which seems to be the fatal heritage of so many Hybrid Teas, although clearly showing its mixed race by its habit, and by the great branching trusses of bloom which crown the sucker-like shoots that spring from the base of the plant, is deservedly placed among the greatest of "the great Roses," being fair in form, bountiful as fair, and strong as bountiful, flowering early and late, and bringing to a high perfection a larger number of flowers than any other Rose in cultivation—a number which might have seemed incredible for a variety whose blooms are liable to expand somewhat rapidly under a hot sun, and to which, from the texture and multiplicity of their petals, there accrues considerable danger from wet.

Madame Gabriel Luizet is an extremely vigorous grower, and produces an abundance of flowers of a tender and unique rose colour. This variety at one time did not seem likely to prove an autumnal bloomer, and some rosarians were disposed to regard it as a Hybrid China, an opinion strengthened by the liability of the plant to mildew; but established cut-backs flower a second time, and throughout the autumn of 1886 correspondence was frequent on the number and beauty of blooms of this Rose produced in various parts of the country. While none of the other varieties mentioned need be planted more than 2 feet apart, there should be 3 feet between the plants of Madame Gabriel Luizet in order that her "ample charms" may be satisfactorily displayed and thus generously treated she will afford an immense wealth of her peculiarly delicately-hued blossoms. Violette Bouyer, in addition to being one of the most good-natured of Roses, is by far the most attractive of the white Hybrid Perpetuals; not always so white, perhaps, as Merveille de Lyon (though a snowy bloom is now and then obtained), but in grace of form and growth it always excels the "Rothschild Ghost," whose complexion could hardly be expected to be otherwise than a somewhat dead white. It is undeniable that the flowers of Violette Bouyer are often washed with a faint tinge of pink on the outside of the petals, but they may be practically regarded as white, and are, beyond question, beautiful. The variety is described by its raiser, M. Lacharme, as a seedling from Jules Margottin, and it inherits its parent's good qualities of hardness, vigour, freedom in flowering both in summer and autumn, and fragrance; if it were only exempt from mildew, it would be without reproach.

If more varieties in the same section be required for effective massing in the garden, the following are all first-rate for the purpose: Alphonse Souperet, deep rose and very free-flowering; Alfred Dumesnil, a brilliant and handsome Rose far too seldom met with; Captain Christy; Catherine Souperet, a useful light Rose which often makes a greater effect in the garden than many other varieties of its colour, owing to the protection from the raids of fair fingers which is afforded to its blossoms by the numerous strong prickles that cover the wood; Duke of Connaught (Paul), a hardy and good dark crimson Rose which might well be more generally grown; Dupuy Jamain; Jules Margottin; Marguerite de St. Anand; Marguerite de Roman, very free-flowering and very lovely, though not a tall grower, and one which, like the four following, need not be planted more than 1½ feet apart; Marie Finger; Marquise de Castellane; Merveille de Lyon, a fuller flower than White Baroness, but not always more effective in the garden, owing to the greater ability of the latter to resist the effects of wet and to expand without being discoloured in rainy weather; Rosieriste Jacobs, a valuable dark Rose, flowering freely in autumn; and Ulrich Brunner, almost an Evergreen, growing like a Willow, carrying its handsome foliage through the driest summer, practically exempt from mildew and one of the few varieties of Hybrid Perpetuals which in the trying season of 1886 successfully resisted the attacks of Orange fungus, and produced flowers large and bright in abundance both in summer and autumn.

All these Roses, with the exception of White Baroness, are among those most highly prized by exhibitors as furnishing the perfectly formed flowers necessary for prize-winning at Rose shows in these days of keen competition; but there are three Hybrid Perpetuals, which, though lacking the regularity of form and outline demanded by florist-judges, cannot nevertheless be omitted from a selection of varieties intended for inspection in their natural position growing on the plant rather than in an exhibition tent. Two of these have already attained to a respectable age, having both been sent out in 1859, the third making its appearance exactly twenty years later. The first of the twins is Anna Alexiell, a most attractive, bright, rose-pink flower, abundantly produced early and late, and which, although it opens rather flat, does not lose colour on expanding; the plant is hardy and handsome, the bright green foliage being well set off by the brown stems, and for making a large, bold group, no variety would be more striking. The second twin, Eugène Appert, is one of the handsomest-foliaged Roses ever raised, and if its flowers are somewhat flat and short-petalled, their maroon-crimson colouring is unquestionably gorgeous. The third variety referred to is Préfet Limbourg, a very free-growing, branching plant, which produces—on shoots apparently too slender to carry anything much, but in reality very hard and stiff—a profusion of deep crimson, purple-shaded flowers, open and cup-shaped, but lasting well on the tree, and being exceptionally fine and well-coloured in autumn. In a cool season this Rose gives flowers sufficiently full and well-formed to admit of their being successfully exhibited, and it is further worth growing as being hardy and fairly exempt from mildew.

Any of the above-named Hybrid Perpetuals, if worked as dwarf plants upon Brier cutting or seedling stocks, will make handsome groups and a bright effect of colour in the garden; and though most of them produce flowers perfect enough in form to satisfy the keenest critic from the florist's point of view, this need deter no one

who is prepared to give his Rose trees any cultural attention from growing them, as they are also among the best-constituted, most constant, and most truly beautiful of all Roses.

ROSE ARCHES.

ARCHES and Roses are both so gardenesque, either singly or combined, that it seems a pity that the two are not more frequently linked together to the enrichment of modern landscapes. They were almost too common and mostly too heavy in the olden times. In many old-fashioned gardens it was no uncommon thing to find so-called Rose arches and arbours in which the timbers far out-bulked and overweighed the Roses, and doubtless such incongruous blendings of live and dead weights did much to clear away many Rose arches—good, bad, and indifferent. Like many another raid against abuses, the clearance of Rose arches was carried to extremes, and bore down before it many of the most charming retreats of old-fashioned gardens, from which the dust, din, and glare of the world were shut out, and all the sweetness of the Roses from myriads of drooping wreathlets was shut in.

From the pen-and-pencil sketches now appearing in THE GARDEN, it is obvious that not a few readers are ready to welcome back the charms, while leaving behind the faults, of the ancient Rose arches, or to construct and plant modern ones of yet greater beauty. We have a series of arches that run along one side and through the centre of a large flower garden. These are wide and high, the chief lines of arches running along one side and along each end of the garden as well. In the chief and largest series the sides of the arches are filled in with others, spanning the distance between the cross arch so that the arches are all multiples of fours. The artistic effect is rich and striking, and the mechanical advantages are very great, giving, in fact, the utmost solidity and virtual immobility to the entire series of arches.

The height of the main arches is 12½ feet, the width 8 feet, the distance between the arches the same as the width of the span, and the length of the longest series 320 feet. Some of the others that span the Grass walks are 13 ft. high by 12 ft. wide. They are formed of pipes, which are stronger, lighter, and cheaper than solid bars, the additional circumference also being a great practical advantage in the training and tying of the Roses. It is also thought that these hollow tubes are warmer and less liable to attract lightning than solid iron rods. If so, these are great practical advantages, as the extreme rapidity with which iron conducts the heat of the Roses out of the stems and shoots in contact with it during severe frost not seldom leaves frost-bites that result in gangrene and death; and no one but those who have had a considerable extent of rather lofty Rose arches under their care, and have noted the frequent and sudden deaths from lightning strokes, will be able to appreciate how welcome any promise of immunity from this real peril, through hollow pipes or otherwise, is to the zealous cultivator. Be all this as it may, hollow pipes are best, lightest, cheapest, easiest bent into perfect form, and strongest. The form of Rose arches is important. Due proportion of height to width, and of both to distance, proper relations to height of standard, and height and width of span all need due consideration. The main series of arches here are 8 feet up to the spring, thus giving a rise of 4 feet from the side to the crown of the arch. The ends and centre arches are wider and higher by about a foot, and maintain the same proportionate rise from sides to centre. For Rose arches, too, the round form is the best. Gothic or any imitation of pointed arches are less satisfactory. Nor should any attempt at all be made to fill in the arches with additional iron or wire for training. Not a few Rose arches have thus been ruined by an excess of training surface. Where this has been provided, it is the least of two evils to leave it unfinished, unless the bolder plan is adopted of clearing it away.

Rose arches are one thing, Rose arbours another; and whatever views are held about the latter, the conversion of arches into a sort of hybrid arbour, which is often done, is seldom satisfactory.

One of the great merits of Rose arches is the boldness and sharpness with which they stand out against the interstices between or from the connecting arches that may link two arches together and the sides, and the furnishing and form of the pillars that support them. By filling in the sides with iron and additional drapery of Roses, Clematises, Honeysuckles, and other climbers, we lower the dignity and grandeur, grace and beauty of our arches. Arches also add greatly to the effect of statuary, vases, fountains, and spiral trees and shrubs. The effects of such are marvellously enriched and enhanced—partially revealed and partially concealed—by the drooping drapery of graceful Rose shoots sweeping down from the crown or sides of lofty arches. As to the furnishing of arches, there is little to add to what has been so well said lately in THE GARDEN. A complete arch of a sort, and such a choice of varieties as will ensure a heyday of beauty at a given period, as well as a skilful blending of colours, are all essential to those who would reap the highest decorative results from Rose arches. Small rather than large-foliaged sorts should also be chosen, alike to save the leaves from being riven into ragged fragments by winds, and because they lend themselves best to either close or loose training over arches. Decided colours, too, should only be chosen. As a rule, purples and pale pinks are dead and useless for ornamental purposes over arches. A liberal use of whites is always telling, and these should be lighted up with as many brilliant pinks and fiery crimsons as can be had. Notwithstanding the Roses named for arches on pp. 93 and 94, and a good many others that have been found more or less useful, there is still a great want of Roses of brilliant colour, hardy constitutions, profuse and continuous flowering for this purpose. For while, as already stated, the once popular arch fell into dis favour and disappeared from our gardens very much by its sheer weight and massive ugliness, there can be little doubt that the insipid colouring and worthless character of many of the Roses used to clothe the arches largely assisted in their overthrow. Neither lightness of structure nor beauty of form could have withstood the dead colourless mixture that buried out of sight, rather than revealed with more distinctness, the beauty of the arches. D. T. F.

Her Majesty Rose in America.—I noticed that Mr. Mansfield Milton, like hundreds of others, is in bad humour with Her Majesty, but no one here is to blame. Mr. Evans purchased the stock from Mr. Bennett in 1884, and if it was then in the same condition as I saw it on Mr. Bennett's grounds in England in 1885, he certainly was not to blame for giving it the extraordinary praise with which it was heralded, for, with all my long experience in such matters, its merits as seen there so impressed me that I did not wait to come home, but ordered from London direct one thousand plants of it from Mr. Robert Craig. This was my judgment in the matter, mistaken as it proved to be. In all Mr. Bennett's stock of some 10,000 plants I did not see a speck of mildew on Her Majesty, and although the weather was hot and dry, the flowers shown were all that had been claimed for them. But it is evident Her Majesty will never reign in this democratic soil. She not alone besmears herself with mildew in a way that no other Rose ever did, but she seems absolutely to refuse to show her regal claim to beauty unless under the very best conditions. In the thousand plants that I got from Mr. Craig, only some five showed flower out of the whole lot. Almost any other Rose from such plants would have given 100 per cent. in flowers. And she does not seem to acclimatise either. Fine plants grown here, though fairly free from mildew, show the same shyness in blooming, so that Her Majesty's reign, in America at least, may be said to be completely over. But we should not complain of being bit now and then,

when it can be shown, as in this case, that it is not done to deceive, particularly when we know that in the William Francis Bennett Rose, sent out by the same raiser, we have a set-off that well balances the disappointment in Her Majesty, for our experience with the Bennett last winter, and up to the present time this winter, shows it to be by all odds the most profitable of all Roses grown for cut flowers in winter.—PETER HENDERSON, in *Gardener's Monthly*.

FLOWER GARDEN.

SPRING CROCUSES.

C. CAMBESSEDESI is a charming little Crocus, which, though in its native habitat is said to flower regularly in October and November, becomes very variable under cultivation, flowering in mild intervals from September to April, and making an interesting display during the dullest season of the year. Its flowers are, however, unfortunately small, the segments being not more than three-quarters of an inch long; they are, however, very bright in colour. The three outer ones are pale buff, handsomely marked externally with purple featherings; the inner three vary from white to pale lilac. It is a native of Minorea and Majorea, and is now in flower at Kew. **C. Imperati**, another beautiful species, is also in flower at Kew, being fully a fortnight earlier than it was last year, and a few days earlier than in the spring of 1885. Mr. Maw says it is abundant in the south of Naples, and it is said to extend into Calabria. It is, however, perfectly hardy in the open air in this country, and is one of the most useful species which we have for planting in turf. It excels even *C. nudiflorus* as regards profusion of flowers, and is also in robustness. With the exception of *C. biflorus* and its varieties, it increases much more rapidly than any of the other spring species. The flowers, both in their colour and markings, are extremely variable, as well as in the amount of sub-division of the stigmas, many being divided into fine thread-like appendages, while others are almost entire, thus relating it closely to *C. suaveolens*. The segments are about 2 inches long, and about half that in breadth; the outer three are buff, with pretty purple-feathered markings; the inner three bright purple, but sometimes they are rosy red, and even pure white. **C. Korolkowi**.—This species is also earlier than usual this year by a week. It is comparatively new, and as yet rare. It merits a place, however, in every garden, both on account of its beautiful orange flowers and the early season at which they are produced. Coming as it does from Western Turkestan, it is sure to be hardy in the open air. **C. vitellinus**, a handsome orange species, and one which we find to be amenable to cultivation on turf, is just now opening its flowers, and is really a very charming and desirable kind. **C. hyemalis** is also opening its flowers, and it will soon be followed by others, which are just pushing their leaves through the ground. K.

Narcissus cyclamineus.—This distinct little species, which I described in THE GARDEN (p. 127), was re-discovered by Mr. Johnston, of Oporto, and both he and Mr. Tait wished that if new it might bear the name of Professor Henriquez, of Coimbra, who takes much interest in the native plants of Portugal. Mr. Tait tells me that bulbs planted in his garden at Oporto opened their first flowers on January 28, and a few days after they flowered with us in a sunny greenhouse, and he adds that in its native habitat the wild plants will not bloom until a fortnight later—say about the middle of February. Seeds grow freely, germinating in about a month after being sown.—F. W. BURBIDGE, *Trinity College Botanic Gardens, Dublin*.

GLADIOLI AND THEIR CULTURE.

"DELTA'S" remarks on Gladioli (p. 144) will help us to arrive at a definite conclusion as to the best way in which to manage them. But one important item ought always to be included, although "Delta" has omitted it, and that is, the situation of the garden and the amount of the autumn rainfall. I find that at Cambridge the average for the year from six observers is only 22.34 inches; at Northampton the average from the same number of observers is 27.49 inches; at Southampton the average, from four observers, is 30.58 inches; at Hastings, from five observers, 35.83 inches; at Croydon, from seven observers, 28.94 inches; at Ashford, in Kent, from two observers, 31.20 inches; at Derby, about 35 inches; Warrington, 33 inches; and at Cardiff, 45.91 inches. It would thus appear that Cambridge is a comparatively dry district; besides, the position of Mr. Burrell's garden may also be otherwise favourable as regards Gladioli. I may add that in the same year in which the averages just quoted were taken, viz., 1878, I had many losses amongst our bulbs; indeed, we were quite disheartened, but our rainfall was 29.43 inches, or 7 inches more than that in Mr. Burrell's district. It might be safe for one so favourably situated as to rainfall, and perhaps temperature, to leave the bulbs out in the open garden until December; whereas if another under more adverse conditions was to act in a similar manner, the results might be very different. I cannot say what may be the amount of rainfall in "Delta's" district, but even at Ashford it is about 9 inches more than at Cambridge—a very material difference when we consider that probably an inch or two of rain more may fall in one place than it does at the other in the late autumn months. In our district it is impossible that there can be any ripening of bulbs after the last week in October. I have left them out until November, but they were always the worse for it. I may also say that we had no difficulty in growing large bulbs; in fact, those which we had from France became three times as large as they were when received after the first year's growth. The soil on which they grew was very light and over gravel. Probably a heavier soil might have suited them better, but I have always understood that the French growers cultivate their bulbs on light soils, and our own bulbs were generally better looking than the imported ones; but the flowering time invariably proved that the French bulbs were the best for producing long, handsome spikes. I have not grown any of the *gandavensis* hybrids for three or four years, but if I ever had the chance to grow them again my plan would be to purchase, say, a dozen of the best varieties, and, having obtained them, I would plant them in a warm position about the 1st of March. They would flower early—say the first week in August—when it would be interesting work to hybridise the flowers. Sufficient seeds could be obtained to raise about 2000 plants, which would not flower the next season, but they would do so the second year, and would produce vigorous plants and spikes of as good quality as those generally seen at exhibitions. The seedlings are generally as good as most of the named varieties. J. DOUGLAS.

Iris stylosa.—This species was the first to bloom with us this year, and on the 29th of last month I. Histro, which is planted in the sunniest border we have, expanded its first flower under a bell glass, which was necessary for its protection against our uncertain weather. This is certainly a lovely plant, but a somewhat scanty bloomer, while the first mentioned is just the opposite, and well adapted for pot culture, as we get good results without any special attention as regards treatment. It continues blooming for a lengthened period. *I. reticulata*, figured in THE GARDEN, plate 503, is another very early one to bloom, and should be grown by all who have to keep up a continual display in the greenhouse.—W. H.

Utricularias.—On a recent visit to St. Albans we observed *U. Humboldti* growing freely; lovers of Bladder-worts may therefore feel assured that the blue flowers of this kind will soon be forthcoming

This plant grows naturally between the sheathing leaves of different species of Bromeliads, and every attempt to introduce it without its nurse-plant has been a failure. Ultimately the Bromeliads were brought home with the *Utricularia* associated with them, and with good results, as young shoots are pushing up all round their stems. Mr. Sander has also a scarlet Bladder-wort (*U. Campbellii*), said to cover whole hill sides in its native habitat. Its flowers are about the size of those of *U. montana*, but instead of being white they are scarlet. Only a few plants, however, have reached this country alive.—G.

YUCCAS AND THEIR USES.

YUCCA GLORIOSA, popularly known as Adam's Needle, is the most majestic of the genus. It grows in drifting sands along the coast from Florida to North Carolina. In favourable situations in this country it grows in some cases to a height of 15 feet, including the flower-stalk. We have seen it growing to the height here given in

Adam's Needle in flower. Engraved for THE GARDEN from a photograph sent by T. J. Couch, Swansea.

sand in a garden close to the sea at Musselburgh. This species flowers freely, and is a very picturesque object in gardens. After flowering the trunk throws out branches, and it is not unusual to see one many times branched. Yuccas are often planted singly, but better effects can be produced by arranging them in groups, the plants of which would flower at different times. The accompanying engraving is from a photograph sent to us by Mr. T. J. Couch, Tremont Terrace, Walter's Road, Swansea. There are other varieties of *Yucca* of great importance to cultivators. The gracefully recurved foliage of *Y. recurva* renders it peculiarly suitable for planting singly; and *Y. filamentosa* and *flaccida* rarely fail to give an abundant crop of ivory-white flowers every autumn. There are dozens of varieties, the use of which would give a distinct feature to a garden.

Helleborus altifolius.—Mr. Archer-Hind states that varieties of *Helleborus niger* do produce pink

stigmas, and I see no reason why the type should not do the same; the obvious difference of pollen-grains seems opposed to crosses with *altifolius*. I send you *niger* (type) from a frame with pink stigma and bud from the open also with pink stigma. I add flowers from seedlings of *niger præcox* with white and pink stigmas, the parent plant having white ones and out of flower when *altifolius* was only in bud; thus, a cross could not have taken place; the flattish flowers of my *altifolius* type, authenticated by the best living authority, have white stigmas. I cannot lay the proofs before you, because the respective flowers are fertilised. I observe that one of the flowers of *Helleborus altifolius* is injured by frost and is withering; so I have cut it and sent it. I hope it will arrive fresh enough to enable you to see that the stigmas are white.—MAX LEICHTLIN, *Baden Baden*.
* * * Clearly white.—ED.

THE PERIWINKLES.

It is singular to find that through all the thirty volumes of THE GARDEN there is scarcely a note about the Periwinkles, invaluable plants as they are, and by no means so commonly planted as one might suppose. To my mind there are few prettier sights in a garden than a shady bank covered with the different sorts of the smaller Periwinkle (*Vinea minor*). In a Sussex garden last year I saw a chalky bank completely carpeted with Periwinkles, the blue, white, and purple colours being intermingled in a charming way, while here and there were masses of the golden and variegated sorts. The smaller Periwinkle (*Vinea minor*) is a wiry little evergreen trailer of a shrubby nature, flowering from spring till autumn at no particular season, but most plentifully in early summer. It is found wild in some parts of England, always in shady hedges and damp spots, and is too common to need further description. The colour of the type is blue; the varieties are the white (*alba*), the violet (*violacea*), and there are also double-flowered forms of each of these colours. Besides these there are the golden-leaved variety (*foliis aureis*) and the variegated-leaved sort (*foliis argenteis*), both of which are very pretty.

The larger Periwinkle (*V. major*) is a much stronger grower than *V. minor*, larger every way, and produces its beautiful blue flowers all throughout the summer, but has not such variety as its smaller relative. It is more suited for clothing rougher places, such as shaded banks and bold rockwork, than the smaller variety. This is one of the very few plants that will grow well under the dense shade of *Beeches*; therefore it is valuable on that account. Like *V. minor*, it grows wild in various parts of Britain, and in the woods and forests in Central and Southern Europe it is abundant. The variegated sort (*elegantissima*) is a pretty plant, particularly when a mass of it is planted near the green variety. I have seen charming effects produced by the Periwinkles, and in one garden I remember seeing a bank densely clothed with *V. major*, as well as a dwarf trellis placed at the top of the bank, and a prettier evergreen screen could not be made. Periwinkles grow best in a moist soil, light or heavy, and they may be propagated easily by runners. W. G.

SHORT NOTES.—FLOWER.

Edwardsia grandiflora.—One of our readers, a cultivator of many hardy plants, tells us that he cannot procure any plants of this. Perhaps some reader will tell us of somebody who has a stock of this pretty wall shrub.

Narcissus pallidus præcox.—Our first bloom of this *Puffball* was gathered out of doors on the 9th inst. The plant from which it was cut looks well in spite of the biting easterly winds and snow, and we hope soon to make copious cuttings.—HERBERT AND MARYEN, *Gerrard*.

Longevity of the Begonia.—What is the experience of readers of THE GARDEN as to the length of time during which *Begonias* will live and flower well? We led them out here in the south of Ireland largely, chiefly the *Vesuvius* type, and I have some bulbs quite a foot in diameter. I believe indeed that some of the same bulbs have been grown here for the last ten or twelve years. Last spring I, however, found numbers of them b-d, and I fear many more will be wrong this year. The cause of their decay is, I think,

their old age. We keep them during winter in a cool Peach house spread on dry clay, fire-heat only being used to exclude frost.—YOUNG GARDENER.

STOVE AND GREENHOUSE.

T. BAINES.

AZALEAS AND INSECT PESTS.

THERE are two matters connected with the cultivation of Azaleas to which is chargeable much of the indifferent condition in which they are sometimes found, viz., the ravages of thrips and the practice of turning the plants out of doors at a time when their growth—wood and leaves alike—is in a soft and not half matured state. The worst effects of immaturity may be seen in the case of plants that have flowered late in spring, and that have not had time to complete the growth started under glass. As a natural consequence, when thus turned out, the shoots at once become hard and wiry, and not over half of them are strong enough to form flower-buds, and of the buds that are produced, many go blind in winter, whilst those that do not do so yield inferior flowers. If Azaleas were not able to bear bad treatment to an extent that few plants would stand, these prematurely exposed plants would fail to flower altogether. In the case of plants that have bloomed during winter or early in spring, and that after flowering have been kept in a genial growing temperature until the season's growth is fully matured and the flower-buds plump and prominent, no harm will follow their being exposed in the open air in summer, provided they are in every way properly attended to. The insects that attack Azaleas are black thrips and red spider, the latter to a much less extent than the former, the spider seldom making its appearance except where the atmosphere is kept too dry and the syringe not used sufficiently.

As soon as winter comes the affected foliage falls off before its time, and the effect of this is that when the time of blooming arrives the flowers are deficient in size and substance and wanting in colour. Nor does the mischief end there; the growth made the ensuing season is proportionately weaker than it should be. Of the various methods for the destruction of thrips on Azaleas, fumigation with some preparation of tobacco or washing with tobacco water, to which is added a little Gishurst, are the most common remedies. Either will kill the living insects, but the former leaves the unhatched eggs unaffected, which in summer come to life in twelve or fourteen days from the time the female insect deposits them and seals them up under the little black specks of varnish-like matter where they are secure until, coming to life, they escape from their covering. The advantage of dipping in or syringing with tobacco water rather than fumigating is that the liquid, when used sufficiently strong and allowed to dry on the leaves—not washed off, as someone was recently advised that it should be—will kill the eggs as well as the mature insects. But to destroy either it is scarcely necessary to say that the liquid must reach every leaf; if only a few insects or their eggs are untouched by it all the work has to be done over again. Those who are desirous of growing Azaleas so as to have them in the condition they should be must make up their minds to wage a continuous war against thrips, for even if the plants have been thoroughly freed from them and their eggs, by washing in winter, at which time they cease breeding, it is more than likely that the unwanted company will appear again when the summer comes round. One or two good washings during winter when the insects are not breeding and the hard mature

foliage can bear the liquid stronger is labour well spent, as there is less trouble with them afterwards. Red spider, as already said, seldom becomes troublesome; should it appear, dipping in or syringing with a solution of Gishurst, at about 4 ounces to the gallon of water, will effect a riddance.

Although Azaleas are fine-rooted plants, they, nevertheless, produce roots in immense quantities when healthy and strong; consequently to keep up the requisite vigour they require manurial assistance. As it is better not to add anything in the shape of manure to the soil they are potted in, it becomes necessary to assist them during the time the summer's growth is being made, without which it is useless to expect the plants after they have got a few years old to make shoots long enough to admit of the flowers being cut with sufficient wood attached to be of use, without which in these times, when flowers of all kinds are wanted in untold quantities, their value is much reduced. Half the Azaleas one meets with that have attained any size are in this condition, the growth annually forthcoming being not more than a few inches long; whereas, if the right varieties are selected and the plants are as strong and healthy as they should be, much of the growth which they make will be 6 inches or 8 inches in length. Weak, puny-growing varieties are not worth the room they occupy, however taking the flowers may be in appearance. The market growers who supply Covent Garden with Azalea flowers get unusual growth out of their plants every season, though in the case of several that I know the plants are from forty to fifty years old, running from 8 feet to 9 feet high by as much through, the shoots yearly made being from 6 inches to 12 inches long. A sight of these plants in autumn, with their flower-buds big and hard, shows that only a small per-centage of the shoots have failed to set, and of those that have set few escape the knife, the flowers being cut with three-fourths of the season's wood attached. Considering the age of the plants, with the comparatively little pot-room they have, and the severe cutting they are annually subjected to, it would not be possible to get such growth without constant feeding. The subject of manure is a wide and a very important one, about which it is not necessary to say much here, further than that the old notion which used to prevail, that if a manure was found to be the best for some particular kind of plant, it must be the best for all, and is fast giving way to a more rational idea. I have tried manure water made from the excrements, solid and fluid, of the various animals usually found in the farmyard, and most of the different concentrated manures, in either liquid form or laid on the surface to be washed down to the roots in the ordinary process of watering; but nothing that I have used was so good as Standen's manure for Azaleas, dusted on the surface of the balls. In addition to the growth it puts into the plants, there is the advantage that, whilst acting quickly enough to influence the growth as soon as it is applied, it is not soluble in water to an extent that admits of its being washed down to the roots at a greater strength than they can bear; whereas, when strong manures that at once dissolve as soon as water reaches them are applied to the surface of the balls, it follows that the first time water is given it carries the essence of the manure down to the roots at a strength which they cannot stand. Many a fine plant has been killed in this way, and at the same time a good manure has got a bad name, both mistakes arising through the obvious cause of the manure being used without due caution. It is generally looked upon as sound practice to defer the potting of any plant

until its roots are actually in motion, or just about to move. For this reason it is better to leave the potting of Azaleas until after they have bloomed, even in the case of those that have been retarded in the time of their flowering, so that they do not come in until the end of the spring, as the roots of Azaleas, unlike those of most plants, do not move at all till after they have flowered, although when strong and healthy they will have made a good deal of shoot-growth before the flowers have opened. I like to defer the potting of such as require shifting until two or three weeks after the flowers have fallen. Immediately this takes place, the seed-pods should be picked off, as if this is delayed even a short time, the formation of the seeds that goes on as soon as the flowers drop is so much of the energies of the plants expended to no purpose. When the plants get large, say from 4 feet to 5 feet high and as much through, occupying pots 16 inches or 18 inches in diameter, they may be kept in a vigorous, healthy state for years by the use of manure water whilst their growth is being made without additional pot-room.

Azaleas are light-loving plants and should be kept well up to the glass during the time they are making their growth, and no more shade should be used than a slight protection whilst the sun is powerful. When the growth is made under conditions of insufficient light the leaves are wanting in substance, and generally fall off in winter to an extent that has a weakening influence. Whilst growth is going on the syringe should be used once a day in the afternoons freely, so as to wet the foliage thoroughly on the under as well as on the upper surface. This helps to keep down insects as well as promote growth. The practice of pinching out all the young shoots that often precede the opening of the flowers is about as great a mistake as can well be committed, as it is highly injurious in its effects. The removal of the shoots in this way is usually done under the impression that if they are allowed to grow, the flower-buds will go blind, of which there is little danger if they have been properly matured in the autumn, unless the roots have been kept too dry in the winter, a condition that Azaleas should never be subjected to, as they do not like, even when at rest, to have the soil nearly so dry as some hard-wooded plants require it to be. If the shoots are weak and more numerous than necessary, it is a good plan to thin them well out, leaving the strongest untouched.

As to the newer varieties of Azalea that have appeared within the last ten or twelve years, their flowers are more perfect in shape, according to the arbitrary standard that requires a circular outline, but to those who see more beauty in a flower that has something of natural irregularity about it, they are the reverse of an improvement; there is, too, this about these newer Azaleas which is not pleasing—either they are wanting in that freedom of growth that enabled the older varieties, such, for instance, as the seedlings raised by Ivery, Kinghorn and others to attain size, or the growers that now take them in hand are incapable of getting them on, for many of the varieties in question have been growing long enough to have reached specimen size; yet, hitherto they have been rarely, if ever, seen in anything larger than the little bushy, Mushroom-headed examples such as continental growers produce.

T. B.

Uro-Skinnera spectabilis.—Among stove plants in flower at the present time this is one that will at once attract attention. Although it has been introduced into British gardens about twenty-five years, it is still quite rare, and that not from any difficulty attending its cultivation, for it is very

easily grown. This plant (the only one belonging to the genus as far as I know) was introduced from South America, and bears when out of bloom a certain amount of resemblance to some of the Gesneras, but the flowers are altogether different. The blossoms are borne in terminal clusters on stoutish stems a foot or two high, clothed as well as the foliage thickly with hairs. Individually the blossoms are somewhat like a *Penstemon*, the tube being about $1\frac{1}{2}$ inches long, deep mauve on the outside and white within, while the flower measures three-quarters of an inch or so across the mouth. As each cluster contains about a score of blossoms, they make a goodly show.—H. P.

HARDINESS OF *FICUS REPENS*.

FICUS REPENS is usually classed as a stove plant, but why this should be so I fail to understand. It certainly succeeds well in heat, and is admirably adapted for clothing the back walls of plant stoves and warm ferneries. In such positions it is fairly ornamental, but not enough so, nor so profitable as we like all the occupants of these walls to be, and over the *Ficus*, therefore, we trail *Asparagus plumosus nanus* and *tenuissimus*, *Cissus discolor*, *Selaginella cæsia* and *arborea*, and *Begonias*. It is quite as tenacious of life and as well able to penetrate to the outer side of a wall as the common Ivy. The north-east wall of our fernery is completely clothed on the inside, and partially so on the outside. During a moderately severe winter the growth on the outside is only slightly browned by the weather, this being usually effected by the cold frosty winds. This winter has severely tried it, but though injured it is far from being killed, and I have every confidence in its recovery. For a glass-covered, unheated fernery it is simply invaluable. Planted against any wall or rockwork it will soon spread in all directions, and is quite as able to take care of itself as the popular *Ampelopsis Veitchi*. It is very pretty while clothing the walls or rockwork, and later on when well established every bit of space is perpetually clothed, plenty of loose branches also being formed. I can also strongly recommend it for heated or unheated conservatories, and it is a favourite plant with us for covering the back walls of unheated verandahs, entrance porches, or any somewhat similar position where plants are grown or stood occasionally. In such positions it forms much larger leaves than it does in heat, and is altogether more effective. Instead of being classed as a stove plant it ought to be described as a hardy greenhouse species. Anybody can cultivate it. All that is wanted is a narrow trough disposed along the foot of the wall or other position to be clothed; this being filled with loamy soil will give the plants a good start and suffice to support them for many years. Like the Ivy, it clings naturally to either wood or walls, and a well-established plant soon gets almost independent of its original roots. Scientific observers are disposed to assert that air roots are of no actual service to the plants emitting them, the Ivy being quoted as an example, but I can point to a huge plant against a church tower that has been cut off near the ground for nearly four years and is still healthy, though not so vigorous as before. Some of our plants of *Ficus repens* must be quite as capable of existing independently of the underground roots, as they have gone for weeks together without any water being given them, and yet show no signs of having been neglected. W. I.

Primulas and Gold and Silver Ferns.—Last autumn I planted in a fairly exposed rockery a couple of plants of *Primula obconica*, whose hardiness is generally considered more than doubtful. Since then we have had two smart spells of frost, in which the grass thermometer fell as low as 13° and 16° Fahr.: the first on the snow, the second without snow. The old leaves are gone, but the crown is perfectly uninjured and is now sending up fresh leaves and looks more lively than

P. cortusoides or *P. Sieboldi*. The situation is well drained, and although we had on each occasion several successive nights of keen frost, none were so severe as those named. *Veronica Hulkeana* in an open bed is also quite uninjured. The powdered *Gymnogrammas* are usually considered to require a high temperature to grow them in any way satisfactorily, and the same remark applies to *Nepenthes*. I have two little houses usually kept at barely intermediate temperature, say 45° or 50° as a minimum in winter, and scarcely any fireheat in summer. In these I have several Golden and Silver Ferns, nearly all self-sown. A golden one about five years old has for some time filled an 11-inch pot cram full, and bears fronds over 2 feet long and richly powdered. A silver seedling (*tartarea*?) on a block is also growing vigorously. An accident occurred in December to the heating, and for a week during sharp frosty weather we had next to no heat, the temperature ranging from 35° to 40° for a week. These *Gymnogrammas* are entirely unharmed, though many other things suffered severely. As to *Nepenthes*, I have two which grow well in the same house; one has grown from a seedling in a $2\frac{1}{2}$ -inch pot to fill a large basket and produces plenty of fair-sized pitchers. Hence I contend these are not so delicate as has usually been supposed, although I admit I would prefer to give them more heat if I could. I have repeatedly tried *Allamandas* and *Clerodendrons* and *Fittonia argyrenæna*, but always lose them in winter. Nor can I flower *Calanthes*, though they make good growth.—GREENWOOD PIM, *Moulshottown, Dublin*.

Callas are now grown largely for market, and the ordinary plan is to use single crowns in 3-inch or 6-inch pots. In private gardens a few large specimens with from eight to twelve crowns in a pot make grand plants for conservatory decoration, as, when well grown, the foliage is very ornamental even when there are no flowers. I lately saw some that had been in the same pots three seasons: all the small offsets had been removed, and after flowering the old soil had been taken out as much as possible, and a good surfacing of rotten manure and copious supplies of liquid manure had been applied, and finer plants than were produced under this treatment could not be desired.—J. G. H.

Primula floribunda.—I sowed a pan of seed of this perpetual blooming little beauty in September last. The seed germinated like Cress, and for the last month almost every plant has been in full blossom. Few things bloom, especially in winter, so soon after sowing or are so bright looking. The seed was saved from a plant given me some time ago by "Veronica," and was raised in a warmish greenhouse. Some are now in a cold house and seem, I think, happier than those in the somewhat warmer temperature. The secret, as with many other *Primulas*, lies, I think, in sowing the seeds as soon as ripe.—GREENWOOD PIM.

Brugmansia suaveolens.—The most effective way in which I have seen this noble-looking plant grown was as a standard at Wynyard Park during Mr. Diek's time. It was at first, I believe, grown in a tub, but Mr. Diek had it planted out in a corner of the large conservatory there. The main stem was as thick as one's leg. It was pruned back every season like a Rose tree. It usually threw out from twelve to twenty massive shoots from 6 feet to 8 feet in length; these were kept in proper form by being looped with twine from one support in the centre. Thus treated, its effect when in bloom was grand, while its perfume filled the whole conservatory.—W. WATSON, *Englehurst, Farley, Hants*.

Boronias and their culture.—I was pleased to see attention directed to *Boronias* the other day in THE GARDEN. They are plants which should be in every greenhouse. They are by no means difficult to manage; cuttings of half ripened wood taken in summer and inserted in a properly prepared pot, filled with peat, leaf-mould, and plenty of sand, strike freely. They should be covered with a bell-glass and placed in gentle heat, taking care that they do not damp off. Pot them when

rooted in $2\frac{1}{2}$ -inch pots, and when established, they may be removed to the greenhouse, or to any cool airy position, where during winter they will require but little water. Young plants of *Boronias* should be repotted in April, and all others as soon as they have finished flowering; give them a good open compost, consisting of fibrous peat and plenty of sharp sand, taking care that the pots are well drained. Place them in a nice warm house, and keep them rather close, in order to induce them to make growth until August, when they should be removed to a cool greenhouse. *B. serrulata* is a useful species; it has smooth bright green leaves and rose coloured flowers, which are produced in May. *B. Drummondii*, a compact growing plant, has pink flowers, which are produced in great abundance during May and June. *B. elatior*, another fine kind, produces rosy carmine flowers in dense clusters towards the ends of the shoots. *B. pinnata*, the best known of all the *Boronias*, is also very pretty, as is likewise *B. megastigma*, a variety with chocolate coloured flowers and very sweetly scented.—C. C., *Horrick*.

THE NELUMBUM.

Mr. FRANK MILES, in THE GARDEN (p. 126), says that Theophrastus or somebody is making a mistake when they assert that the *Nelumbium* has thorns. I ought perhaps to have written "prickles" instead of "thorns," and translated Theophrastus *ἀκάρβα* "prickles" also. But perhaps Mr. Miles received his specimens from Japan or China, where this plant has been cultivated from time immemorial. These cultivated prickles, I am fully aware, only produce slender prickles approaching to stiffened hairs, but in the wilds of India and Burmah, where the plant grows in its greatest luxuriance, these prickles are much developed and quite worthy of the name "thorn," although that term is botanically incorrect. Mr. Miles asserts that the sacred Lotus of Egypt was the *Nymphaea Lotus*. This is quite a mistake. The Water Lily represented on the ancient monuments is the *Nymphaea cærulea*, as anyone can see. On the ancient mural paintings, in almost every instance where the colour of the flower is preserved, it is blue, and in numerous places, even where the colour has vanished, we can distinguish the blue species by its leaves. The leaf of *N. cærulea* has an entire margin, that of *N. Lotus* a dentated one. I only know of a single instance where the white species can be detected, and this occurs on a tomb at Beni Hassan, and is figured in the first volume of Napoleon's great work, "Description de l'Égypte," section antiquities.

It is curious that, although representations of *Nymphaea cærulea* occur so largely on the ancient monuments of Egypt, only one ancient author should mention it. This author is Athenæus (*Deipn.* xv., 6). He calls it *Lotinos*, and notes that it grew on the Nile near Alexandria.

The *Nelumbium speciosum* was introduced into Egypt probably about the time of the Persian invasion, and seems to have wholly taken the place of *N. cærulea*, so far as art is concerned. Representations of it are largely used on gnostic gems; and on an old mosaic known as the mosaic of Palestrina, illustrating Hadrian in Egypt, this plant is figured growing wild on the banks of the Nile.

Theophrastus (*iv.*, 10) notes it was produced in Syria and Torone, where it ripened its seeds, but he mentions that about Cilicia it did not come to maturity. Alexander (*Strabo xv.*, 1, 25) observed it growing in Akesinus (now called the Chenab). It was cultivated in Greece in a certain marsh by the river Thyamus in Epirus (*Athen Deipn.* iii., 2). If Pliny's *Colocasia* (*Bk. xiii.*, 51) was the *Nelumbium*, which it seems unreasonable to suppose otherwise, it was also cultivated in Italy. After Pliny, I believe the plant was not noticed by any European writer until the time of Clusius (1605), who has a figure of the true fruit in his "*Exoticorum Plantarum Historia*," p. 32. This fruit, so a later writer, John Parkinson (1629),

tells us, was brought to Amsterdam by Dutch mariners from Java.

P. E. N.

Upper Norwood.

Libonia floribunda.—This little compact-growing plant I find very useful at this time of the year as a vase plant, or in a cut state for the drawing-room, or for the embellishment of the conservatory. The treatment it receives here is most simple. When done blooming, which is about the end of February, the plants are headed back to within a joint or so of the last season's growth, placed in a temperature of about 60°, and kept dry at the root until such time as they show signs of growth, when a little water is given, but when growth has fairly commenced water is given freely. In April they are moved to cooler quarters and gradually hardened off. About the end of May or beginning of June they are planted out on a sheltered, sunny border about 2 feet apart each way; if the ground is dry they have a good watering as soon as planted. Here they soon commence to grow, and all the care they need until the time they are lifted is an occasional watering, should the weather prove dry. By the end of September they will have grown into nice stocky bushes about 18 inches to 2 feet through. Early in October they are taken up carefully, and any loose soil shaken away. They are put into as small pots as possible, leaving room for a little fresh soil to cover the roots, and to hold water sufficient to soak the ball through. They are then placed in a cold pit, watered, and kept close and well syringed for a week or ten days. They soon recover from the effects of lifting, and begin rapidly to show their flower buds. In November they are brought into a warm greenhouse, where they soon begin to open their orange and red flowers. By the middle of January they are, if well managed, one mass of bloom, and very effective. *L. perthensis* is also a good winter bloomer, but with me it does not do well planted out, as it apparently requires more heat than *floribunda*. Its flowers are brighter than the other, but the plant is of a more straggly habit, and requires tying to have shapely plants.—W. WATSON, *Englehurst.*

SHORT NOTE.—STOVE AND GREENHOUSE.

Rhododendron Duchess of Edinburgh.—This variety, on account of its bright orange-scarlet flowers, is now very conspicuous in the large collection of greenhouse Rhododendrons grown by Messrs. Veitch at Chelsea.

Citrus smensis.—Any one looking about for plants for table decoration would do well to try this Citrus. We saw the other day dwarf plants of it growing in 5-inch and 6-inch pots, and bearing on an average twelve beautiful fruits, which were set off to advantage by the bright green foliage with which they were associated.

Livistona rotundifolia.—Now that plants in rooms have become indispensable, and Palms are in greater demand for that purpose than anything else, this *Livistona* will undoubtedly command itself. It is very dwarf, of free growth, and on some plants we counted on an average from ten to twelve fully developed leaves.

Azalea Deutsche Perle.—This pretty little variety ought to be grown by everyone who has to keep up a supply of plants in flower during winter and early spring. The flowers, which are pure white, are produced very freely on small plants. It can also be recommended from the fact that it stands forcing well.

Monochaetum Lemonianum.—This species, at once the most robust and hardiest belonging to the genus, is now finely in flower in Messrs. Veitch's nursery. Its flowers, which are of a beautiful reddish violet hue, are produced in great abundance on dense bushy plants. They also have the merit of resisting the London fogs, which are as a rule so destructive to flowers.

Toxicophlea spectabilis.—We saw the other day very beautiful little specimens of this handsome stove plant in 3-inch pots one sheet of bloom and in addition to their being so abundant, they have also the advantage of being very sweetly scented. In habit the plant is very bushy, and produces its white flowers in corymbs at the point of every shoot, and also from the axils of the leaves.

Begonia Gloire de Sceaux.—This variety flowers during the dull season, and is easy of cultivation, two points greatly in its favour. The flowers, which are pink, are set off to advantage by the dark metallic hue of the foliage. Planted out in winter gardens it grows and flowers freely. In many cases plants of it have been seen 2 feet high and 2½ feet across, and covered with flowers. It also blooms in a very small state.

Kentia Fosteriana variegata.—The typical form of this plant is one of the most graceful Palms we have, especially for indoor decoration, its robust constitution enabling it to withstand a low temperature. We recently saw

this in the gardens at Heathersett, Streatham, in which half of each segment in its plume-like leaves is creamy yellow, rendering the whole plant bright and attractive. It has maintained this character from a seedling.

SEASONABLE WORK IN PLANT HOUSES.

GRAFTING CAMELLIAS.—Notwithstanding the numbers of fine sorts of Camellias now in cultivation, there are still to be met with here and there large healthy examples so inferior as to make them not worth the room they occupy. The remedy for this is to graft them with good kinds. Plants with large bushy heads may thus be obtained in a fourth of the time that young examples take to attain a useful size, with the still further advantage that where large plants have their tops removed and are grafted low down they form heads much more densely furnished at the base than plants that have been grown up from ordinary young stock. I have tried several methods of grafting plants of the description named, the stems of which were from 2 inches to 2½ inches in diameter; one was by taking three or four healthy young plants in pots, standing them on the ball of the plant about to be worked, and inarching their stems in the ordinary way to it, leaving the head of the stock intact until after the young plants were firmly united, when they were severed immediately below the union, at the same time removing the head of the stock. But though this method gives more material to start with than where the stock is grafted with a similar number of scions, still the grafted heads grow away better and freer so as to outstrip the inarched ones. For strong stocks, such as those in question, cleft-grafting is the best, putting four scions in each, covering in the usual way with the ordinary clay mixture. No time should now be lost in heading down any plants that are to be treated in this manner, as if this is not done some time before the sap begins to rise the stools will bleed much. Later on, when the buds of the grafts show signs of pushing, a little extra warmth will be an advantage. During the summer the shoots will most likely require stopping.

AZALEAS.—Most plants should be stood in a warm house or pit, so as to bring them into bloom to keep up a succession for conservatory decoration, and to furnish flowers for cutting. But anything approaching a high forcing temperature must be avoided; when these plants are hurried on into flower in a warm stove heat, the flowers are soft and tender, so that for cutting they are practically useless, as they flag immediately they are severed from the plants and placed in a cool, dry atmosphere. With the same object, there should not be more humidity in the atmosphere than is necessary to assist the flowers to open. Another evil that attends the use of too much heat in bringing Azaleas into flower before the weather gets warm is, that the plants, when in bloom, are usually moved to houses where the temperature is much lower than that in which they have been forced, the effect of which is that the shoot-growth the plants will have made in more or less quantity will receive a check that will interfere with its moving so freely as it should afterwards. Azaleas that were pushed into flower earlier and are now out of bloom should at once be placed in a genial heat, with a moderately moist atmosphere, where they will make growth. The practice of forcing these plants, and afterwards subjecting them to a much lower temperature at the time their growth should be moving freely, is about as inconsistent a course as could well be imagined. Especial care should be taken with plants that are started early to see that they are kept free from thrips, which, if allowed to gain a footing now, will do much injury and cause a deal of trouble afterwards.

ACACIAS AND GENISTAS.—Plants of these that have been forced should, as soon as the flowers are over, be cut in as far as is found necessary, and at once placed for a time where they will have a few degrees more heat than a greenhouse affords, for just in proportion as the plants are thus encouraged to continue the growth that has been excited in bringing them into bloom will they be

in a condition to flower satisfactorily the ensuing year. Any that require more root-room should shortly be moved into larger pots; but grown, as these plants are, for the production of cut flowers, by the removal of which their size is restricted, they require proportionately less root-room. Consequently, it is as well not to overdo them in this matter, especially as much may be done by the use of concentrated manure or manure water to keep up the requisite strength.

EPACRISES.—The long sprays of elegant flowers that these plants continue to produce through the winter months, and which are so well adapted for filling vases, baskets, and other receptacles of a like description, and the gay appearance that they keep up for a length of time in greenhouses and conservatories, entitle them to be much more generally used than they now are. These Epacrises are much handsomer and more useful in every way than the winter-flowering Heaths which, for what reason it would be difficult to say, often get the preference. A limited number of plants that include late as well as early blooming varieties will keep up a succession of flowers for six or seven months. The early-flowered sorts that have done blooming should now have their shoots shortened back previous to their making growth, after which such as require it may be moved to larger pots.

NARCISSUS.—Within comparatively recent times many of the different kinds of Narcissus have been grown as pot plants, and are found to succeed equally as well as the ordinary bunch-flowered sorts that have been so long grown in this way. The best of the large-flowered Daffodils and the different forms of *N. poeticus* succeed as well as could be desired with moderate forcing or with greenhouse treatment. These flowers are in every way deserving of the estimation in which they are now held. To come in before the outdoor supply is available, a sufficient number of bulbs that were potted before their roots began to move should now be placed in a growing temperature. From the time the leaves appear above the soil the plants must be kept well up to the glass, otherwise they get drawn. Henceforward these Narcissi will share favour with the Hyacinths that have so long held the first place, especially as the kinds in question, if well cared for after they have been flowered in pots, soon recover; whilst the Hyacinths, when once they have been forced, do not regain their wonted condition.

PREPARATION FOR POTTING.—Potting materials, including peat, loam, and sand, with a sufficient supply of clean pots and broken crocks, should be got ready for potting the principal portion of the hard-wooded greenhouse plants that require a shift, the greater number of the kinds of which are best repotted sufficiently early to admit of their roots getting hold of the new soil before the hot weather comes on.

STOVE.—It is now time to see to the propagation of the different autumn and winter-flowering plants that are usually grown up to a blooming state from cuttings struck early in the year. Of these the leading kinds are *Salvias*, *Justicias*, *Euphorbia jacquiniiflora*, *Sericographis Ghiesbreghtii*, *Apelandras*, fibrous-rooted *Begonias*, *Centradenias*, *Hebeclinium ianthinum*, *Plumbago rosea*, *Scutellaria Mocciniana*, and *Thyracanthus rutilans*. The chief matter in the cultivation of these plants is to get them sufficiently strong before the autumn comes on, otherwise they will not yield the full quantity of flowers. Quick-growing things like the plants named are, with few exceptions, easily struck from cuttings; of those mentioned, the *Euphorbia* is the only exception, not that cuttings of this plant are difficult to root, provided the young shoots of which they are made are secured in right condition. The plants intended to produce them should have been kept in a brisk heat, so that the shoots may be free in growth; these must be taken off with a heel when they are not more than 5 inches or 6 inches long. If cuttings are made of shoots that have attained considerable length, and severed in the ordinary way without the heel, it is more than likely that not 10 per cent. of them will strike. They must

be kept moist and covered with a propagating glass; the temperature should not be less than 70°. Cuttings of the other plants named prepared in the ordinary manner root freely.

CUTTINGS of Allamandas, Ixoras, Tabernaemontanas, Rondeletias, Clerodendrons (shrubby and climbing), Francisceas, Thunbergias, and Gardenias should now also be put in to strike, as shoots can be obtained in suitable condition. Needless to say that these, in common with most other rapid-growing plants, root and grow away afterwards quickest when the shoots of which they are made, as advised in the case of the Euphorbia, have been produced in a temperature high enough to have pushed them on quickly.

GLORIOSA PLANTI and G. SUTERRA.—The flowers of these plants are singular and effective. The roots should now be potted and stood in the stove, not keeping the soil too wet, until the tops have made some progress.

CURCUMAS.—Roots of these remarkable, but now seldom seen, plants should be turned out of the pots in which they flowered last year, and which have during the winter been kept dry and potted in good light soil; either peat or loam will answer. As soon as potted stand them at the warmest end of the stove, where they will soon begin to move.

HERB PARIS.

(PARIS QUADRIFOLIA.)

THIS strange-looking plant, although it has no striking claim to beauty, is well worthy of culti-

Herb Paris (Paris quadrifolia). Engraved for THE GARDEN from a photograph.

vation in suitable places. It has an interesting, rather weird look, in harmony with its chosen home in cool, damp woodlands. In such places it is delightful to come upon this mysterious plant, with its four broad leaves and green flower. The flower is produced in early summer, and is succeeded by a rather large seed-pod. It is a native plant, but not common.

Eucharis mite.—This pest has been very troublesome in many gardens in this locality. A friend of mine who had his plants severely attacked, after having shaken the bulbs out and having washed the roots clean, dusted them all over with soot, and repotted them in fresh soil. He has since applied soot liberally as a top-dressing, the result being that his Eucharis are now in fine condition, both in pots and planted out. He has a quantity planted close to hot-water pipes, to utilise a spare piece of border, and they made grand growth, the foliage being very fine and dark coloured. Those planted out had been also liberally dressed with soot, washed in with copious supplies of moisture, and although they cannot be regulated as to time of blooming so well as under pot culture, yet they come in well when the blooms are most in request, as they continue

throwing up a few spikes at all times of the year.—G., Hants.

FRUIT GARDEN.

W. COLEMAN.

NUTS AND FILBERTS.

CONFRONTED by the fact that more than half the nuts consumed in this country are imported from abroad, and no one presumes to say the best are better than our Kent Cobs and Filberts, it is hardly likely that the depressed market grower can be told he is suffering from over-production. Prices last year ruled low, but the same may be said of other goods which consumers purchase in smaller quantities, or dispense with altogether when slack trade does not admit of their launching into luxuries. Still there always has been a demand for good quality at paying prices, and these might improve if, instead of confining the nut to Kent, its culture became more general, and dealers could be brought to look upon it as one of our staples, and not as a mere stopgap to be fallen back upon when the foreign supply falls short. But why, without an effort, yield the monopoly to Kent, when throughout Britain there are thousands of acres of land well adapted to the growth of the finest Filberts and nuts if the owners of property would only give them a trial? The common Wood-nut being so well known and

met with in almost every part of this country, to which it is indigenous, the most inexperienced person who has traversed our rural lanes in October can tell at a glance what kind of soil suits it best. On cold, damp clays the fruit is late, watery, and flavourless, but on the banks and hillsides composed usually of warm red loam, often very deep, always well drained, there the Hazel-nut is at home, there above the line of fog and frost, for it flowers early, the crop is good, and the quality superior. It is not, however, of the hard-shelled, beardless *Corylus Avellana* that I wish to speak, as this at best is inferior, but being perhaps the oldest member of the family its presence in a natural state may always be accepted as a safe guide to the selection of a suitable site for the cultivation of the Cob and

Filbert. Assuming, then, that a deep hazel loam in a warm sunny spot is at command, no matter how remote from London or other great marts, for the nut, unlike soft fruits, will keep and travel, there the planter may safely start his nut ground pure and simple, or, by way of variety, bush fruits for the first few years may form every alternate row. In Kent the Filbert is frequently found growing with Hops, Apples, Gooseberries, and Currants, but upon ground specially adapted to nuts, and perhaps far removed from cheap manure, mixed planting should be avoided, as deep trenching followed by light annual top-dressings will keep the trees in health for an indefinite number of years.

PROPAGATION.—Although all the varieties can be raised from seeds and some of them come true, stock generally is raised from suckers, which should be taken up in the autumn, transplanted in lines, and trained to single stems. Of these independent young plants, any number can be obtained from mismanaged plantations, and for this purpose a few old trees of each sort should be allowed to assume their natural habit of

growth, but once the properly prepared trees are transferred to their fruiting quarters, suckering should be repressed, a single stem only tolerated, and then even annual attention will be necessary.

PLANTING.—Like all other deciduous trees, the nut makes the best start when planted early in the autumn, but when raised at home and grown for two or three years in an adjacent nursery they may be transplanted at any time during the season of rest. The distance apart may vary, according to the sorts and the nature of the ground, but sun and light being so important, crowding should be carefully avoided. Where the whole quarter is devoted to nuts, 10 feet to 12 feet from row to row will not be too much, and 9 feet from tree to tree will be found sufficient. When planted in single rows or to form avenues, half this distance from stool to stool will favour the removal of every other plant, as more room is required.

PRUNING.—Where trees are properly formed in the nursery, it is often necessary to cut weakly suckers down to the ground to secure one strong clean growth, which in due course is headed back to the desired height; 18 inches is sufficient for front rows, whilst trees intended for the back may be shortened to 3 feet. If strong, these the following season throw out an abundance of shoots, but five or six being sufficient, all superfluous growths, especially those near the ground, are rubbed off or pinched, whilst those left are trained to form the main ribs of a vase or cup-shaped tree. If any of these take the lead, pinching will throw a flush of sap into the weaker growths, when an equalisation will reduce the next year's pruning to slight shortening, such as we shorten the tips of young Currants or Gooseberries. This shortening results in the growth of a number of short spur-like bits of wood with plump terminal buds, and as these produce the male catkins about January and the female flowers sometimes early in February, the pruning of established trees should always be deferred until the male catkins have performed their office and begin to shrivel. This may be about the end of March, much depending upon the character of the winter, but whenever this stage is reached all superfluous shoots may be cut out, the barren spurs being pruned back to a single bud near the main stems. When trees attain the height of 6 feet they require hard pruning every year not only to keep them well furnished with young spurs, but also to let in light and sun, and, provided they are kept free from stem suckers, they will remain marvels of fertility for a great number of years.

GENERAL CULTIVATION.—When young trees are planted the ground may be cropped with Potatoes or dwarf growing green crops, which will necessitate cleaning, manuring, and working until they come into full bearing and are capable of taking care of themselves. From this time forward the ground should be forked annually and hoed occasionally to keep it free from weeds, but cropping, no longer profitable, may be given up. Meantime, as has been suggested in the management of the Apple orchard, a snug corner should be selected for the manure store. In to this all scrapings and parings from roads, ditch scourings, and a fair percentage of lime should be carted and thoroughly intermixed, together with charred twigs and other refuse ready for the winter dressing. Kentish growers set great value on refuse rags for use in their orchards, but growers in isolated districts cannot conveniently get them. All, however, can adopt the plan I have suggested, and I question if a good top-dressing of fresh compost is not preferable to strong manures.

STORING NUTS.—Many people in this great Hazel district run away with the idea that salt is essential to the preservation of nuts, but this is a fallacy. The first point is thorough ripeness, not only of kernel, but of husk. Then, provided they are to be kept in the latter, they should be well dried in the sun and treated to sulphur fumes prior to storing away in air-tight earthen jars or clean flower-pots. A cool, but dry store room or cellar is a suitable place for the pots. Nuts, however, keep best out of the husk, as they can then be packed tightly and stored away in the cellar or underground, where they retain their fresh flavour and sweetness for many months. When long-bearded nuts have to be kept for a considerable time in the husk, sulphur fumes in a mild form are beneficial rather than otherwise, as they dispel all moisture and destroy the germs of fungi or mould before decomposition sets in.

VARIETIES.—Like all other fruit lists, that of nuts is growing fat, and some of the new kinds, notably those raised by Mr. Webb, of Calcot, near Reading, are said to be very good. For general market or private use the Red and White Filbert. The Cosford and large Cob stand unrivalled, and should be planted in quantity. The Purple Filbert forms a very handsome bush when planted out in the pleasure ground or shrubbery. It bears freely, and the nuts are excellent. If woodland planters would introduce the better varieties, which grow quite as well as the common Hazel, conspicuous parts of our coppice drives might be made more interesting, and certainly not less profitable than they are at present.

ENGLISH V. AMERICAN APPLES.

THE relative value of English and American Apples seems to be of so much importance at this season, that it should be a matter of some interest to all concerned in hardy fruit culture to have the matter tested. In point of colour and beauty we cannot hope to excel the Americans, but if we have other and better qualities in home-grown fruit, then we may claim the advantage. With a view to have the matter tested fairly, I send with this samples of four kinds of Apples, none of which have been specially preserved, and in other hands might have been perhaps better cared for. American Apples are so plentiful in London, that some of the best may doubtless be easily obtained and tried against the samples now sent. No. 1 is the Wellington, esteemed by us as one of the very best Apples for cooking: the fruits sent are from an old standard tree. No. 2 is either Brabant Bellefleur or the old Winter Pearmain. It is a good keeper, and generally a fine sample. The tree is a strong grower and very healthy. These are on the free stock, and eighteen years planted. No. 3 is the Herefordshire, or Royal Pearmain, the fruits of which are now getting rather soft. The tree is on the free stock, old, and never robust. No. 4 is Blenheim Pippin, from an old standard tree in a Buckinghamshire orchard, and, probably not being from the sunny side of the tree, is not so highly coloured as it often is.

A. D.

The Apples sent are very good of their kind, but the Wellington is purely a cooking Apple, which, however, cannot be excelled in its way. The Blenheim is beyond its season, and the others slightly "gone off." We have all the beauty of colour that we can desire in English Apples, but, of course, any opinion that we can express on a small sample like this would go for nothing in the face of the facts of the market. The great value of the scarce Newtown is its fine, high, and acid flavour. We have many excellent English Apples, but good late sorts are very scarce, and our raisers should turn their attention to them. An English Apple as good as the Newtown which would keep up to the present time in good condition would be worth

a king's ransom to the fruit growers of England. Our climate is admirable for Apples, but the fact is that growers generally have not yet begun to compete with the Americans, and there is no doubt that the freehold system of America encourages fruit-tree planting.—Ed.

GRAFFING VINES.

IN Mr. Coleman's admirable instructions on this somewhat difficult matter, page 113, the following sentence is likely to puzzle novices in Vine grafting: "If the stock is very young, the joining of the inner bark of the one to that of the other will not be difficult, but when the stock is old and rough some care will be necessary, otherwise the two will not meet, but overlap, when a perfect union may be doubtful." Now, it will perplex a good many old hands to find the inner bark of the Vine, in the ordinary sense of the phrase, to say nothing of the possibility, or impossibility, of making a perfectly mechanical join or fit between two such ephemeral substances as the inner bark of the Vine scions and stocks. In this phrase Mr. Coleman seems to have slid insensibly into the phraseology of the Apple orchard, to the mystification of Vine grafters, who may seek long without finding any such inner bark on Vines as we are all so familiar with in the case of Apples, Pears, Cherries, &c. It is a mere tautology to add that if there is no such inner bark, it can take no part in the uniting of the scions to the stocks of Vines. Hence it will be found that such union is chiefly or altogether effected through the wood rather than the bark, outer or inner, if such a distinction is permissible to Vine bark, or outer covering of the wood.

It is this vital difference of structure and mode of growth between endogens and exogens that gives additional force to the stress that Mr. Coleman, in common with all successful Vine grafters, lays on the importance of having the stock in full leafage before inserting or fixing the scion. We know that otherwise the scion would be washed off. It is therefore needful to have expanded leaves on the growing Vine as safety-valves for the rush of the sap. But this is not all; these growing leaves ahead of the scion perform an active as well as a passive part in the act, or process rather, of uniting the two parts into one. The outlet of the sap prevents the flooding off, or rotting of the growable rather than growing stem. The energy and what may be termed the adhesive or attractive force of the growing stock takes on and in the more semi-passive scion, and it is not until a later stage that the scion also makes advances to join the stock. No sooner has the latter stage of reciprocal reaction been reached, than the safety and security of the union between the two are ensured. But during the entire process the two woods are the active forces in accelerating the speed and ensuring the soundness and durability of the union rather than the two barks. Hence it is very desirable to have some further information on a question that is hardly important in the grafting of exogens in which the inner bark forms the chief factor, but which assumes vital importance in the grafting of endogenous plants like Vines, and that is the best depth at which to insert the scions into the stocks—a subject on which Mr. Coleman is altogether silent in his otherwise instructive and exhaustive article. On this point there is a wide diversity of opinion and practice. Not a few Vine grafters consider any portion of the stem of stock and scion from the outside to the pith as almost equally eligible and suitable. Others have been successful in cutting both scion and stock boldly down to the pith, and have been more careful to fit these two rather than one on both sides of the so-called bark of the Vine. Possibly most Vine grafters prefer to form their unions about half way from circumference to girth alike on scion and stock. Further information on this point would, I am sure, be gladly welcomed by not a few old hands, who have had considerable practice in Vine grafting, as well as the many "prince hands" whom his article or other circumstance may send knife in hand to try their skill, and maybe their patience also, on their Vines.

A provoking accident first sent me to graft Vines. A friend undertook to supply Vines for two new

houses, and sent plants abnormally strong, but suspiciously alike. But being a cultivator of great note, suspicion was lulled, the Vines planted, and the growths made were most satisfactory. But, alas! the varieties proved all sixes and sevens. It was decided to utilise the root and also the top force as far as possible by grafting the Vines, my friend supplying warranted scions, and giving me various lessons, by letter and illustration, in the true art of Vine grafting. His advice, which was followed, did not greatly differ from Mr. Coleman's, only in addition to whip-grafting the top of the strong rods, as recommended by the latter, one or two buds below the growing points, he strongly recommended the bud-grafting of the young Vines immediately under each growing eye, leaving from six to eight on each. The object was two-fold. As the Vines were to be trained and treated on the spur system, these buds would form spurs in any case for the next year. But by unusual skill and exceptional success, he stated that the strong buds put in would fruit the first year. To this end, he rightly or wrongly attributed great importance to the insertion of the stranger bud at the base of the growing one. So soon as the former took, the growing shoots were stopped, and when the former bud fairly broke into leafage the shoot on the stock was cut clean off. The result was that over 70 per cent. of the buds took, and about 10 per cent. fruited the first year.

I ought, perhaps, to add that these bud-grafts were segments of wood, about a third diameter and about 1½ inches long. They were firmly tied home, cloyed over, and the bud slightly shaded with Moss, and syringed twice or three times a day when the weather was bright. The Vines were grafted in April, and almost every leading shoot reached the top of the house the first season. The bud-grafts that formed the spurs were stopped and treated in the ordinary manner and fruited freely, as did the base of the leading shoots, the following season.

Of course, the growth of the Vines, their great vigour, and the amount of root force in the new borders were all greatly in their favour. But the case is noticed here, as this mode of inserting a sort of bud scion immediately behind the growing spurs has, so far as I am aware, been but little practised, and not previously described.

HORTUS.

Damsons.—In pruning standard trees of the Farleigh Prolific, I have been surprised to find how full they are of buds in spite of the heavy crop borne last year. It is true that the fruit may not follow, but in any case it is pleasing to note that the rudiments of a crop exist. Discussing the merits of the Prune Damson, it is said to hang longer than ordinary Damsons will, but an exception must be made in favour of the Farleigh Prolific, which retains its fruit remarkably well some time after being ripe.—D.

SHORT NOTES.—FRUIT.

Apple Blue Pearmain.—This is a late and useful Apple at this season of the year. It is thus described by Mr. Barron: "Dessert or cooking, large, round, streaked dark purple, with bluish bloom and very handsome."

Apple Starmer Pippin.—This variety, though small, is nevertheless worthy of attention as a late sort. The fruit is somewhat flattened and the skin when ripe yellowish-green, spotted with russet. The flesh is sweet and of first-class quality.

Apple Prince Bismarck.—This handsome Apple, stored in the ordinary way, seems to keep well. It has some resemblance to The Queen, but is superior to that variety. The latter, under the same conditions as to storing, was quite over, while Prince Bismarck was plump and firm, and that, too, after being exhibited at various fruit shows. It was awarded a first-class certificate last season.

Pear Olivier de Serres.—This Pear, which comes into use during February and March, is one of the best late Pears we have, and ought to be grown by everyone who has to keep up a late supply. The fruit is of medium size, skin yellowish, with russet spots, flesh whitish, melting, juicy, and finely perfumed. Some good examples of it were shown at the Pear Congress.

Bigarreau Napoleon III.—In the *Bulletin d'Agriculture* is figured a Cherry under this name. M. Theopoint, a cultivator of stone fruits at Eficbove, states that its fruit hangs long on the tree, which is tall and vigorous and a very good cropper. The fruits, which are generally produced in pairs, are large and roundish-ovate with the stalk inserted in

a deep cavity; the skin is deep red, and when thoroughly ripe of a dark shining purple. The juice is highly coloured, abundant and sweet—said to be a first-rate cherry.

EARLY FRUIT FOR MARKET.

Now that attention is being directed to the question of market fruit growing as a means of utilising agricultural land to greater profit, it may not be amiss to call attention to the claims of the southern counties on account of the great advantage they possess of supplying the earliest fruits of their respective kinds—in fact but very little behind the French, and certainly of superior quality. It has so long been the custom to speak of Kent as the fruit-growing county, that many seem to think that fruit culture is hopeless in any other place; and I grant that for large orchard trees to bear quantity, the deep soil of Kentish valleys can beat us, but certainly not in point of earliness. I need only point to the Strawberry fields here, that have had the first consignment in Covent Garden considerably in advance of any from Kent, and anyone who has experience of market knows that a few days make all the difference; in fact, it is to the very earliest and latest varieties to which growers must turn their attention, and by taking advantage of their climatic differences a great deal might be done to avoid the overstocking of the markets. On the south coast the soil is light and warm, and when the sun shines out brightly the stony land gets very hot, and although it might not look tempting to Kentish fruit growers as the right sort of soil for fruit trees, it is surprising how well they do if only reasonable care be taken to mulch them when drought prevails so as to prevent their suffering from dryness; and if only growers could get over the notion of relying so much on standard trees and would plant dwarf bushes, they might follow very closely on the heels of their French rivals with Cherries, Plums, Apples, Pears, Figs, &c., just as well as they do with Strawberries. Only the very earliest varieties should be grown, and in the best possible manner, and something more approaching garden culture is what is needed, as there are too many old neglected orchard trees already, and I would grow all the trees on the shortest stems possible, so as to be reached by means of a short pair of steps. The trees should be kept pruned in, so that the rays of sunlight can penetrate to warm the soil. This is quite impossible in the old dense-topped orchards, and, above all, the roots must be kept actively at work on the surface, for when they penetrate deep into the sub-soil, strong growth, and not early ripening, follows. This can only be done by annual top dressings of manure, so that the roots always find fresh food ready for them. It is not necessary to have such a dense mass of material as to prevent the warming influence of the sun's rays from reaching the soil, but enough to cover it lightly. In this sort of soil fruit trees make a quantity of fibrous roots, which, if protected, are sure to make fruitful trees or bushes, and only those that are really suitable for the purpose should be planted in quantity, as we have hitherto gone in too much for miscellaneous collections. What we want is some definite plan to proceed on. There is no fear of overstocking the markets with really good fruit, for if one only looks at the enormous imports of Williams' Bon Chrétien Pears alone, it would be acknowledged that there is ample room for home growers to compete for a share of the trade; and that we could grow these things as well as they do in France I am confident, provided we get rid of the idea that any sort of fruit is good enough for market. In Sussex there is fine soil, excellent climate, and within easy distance of the metropolis; and in many parts of Hamp-hire fruits flourish amazingly. Look at our Strawberry fields! why, the soil that produces the finest and earliest fruit is as different as possible from what one would select if guided by old treatises on this luscious fruit; and other fruits are by no means difficult to grow, provided the climate is congenial and the annual growth gets well ripened. Dwarf bushes with natural shaped heads are the ones to plant. On these Apples, Pears, Plums, and Cherries come to

great perfection: even without the aid of walls the colouring of the rosy-cheeked Apples, such as Lady Sudeley, Worcester Pearmain, and Red Quarrenden, is altogether superior to that of fruit grown in what many call more favourable places. As regards Pears, I am confident that the south coast can beat any other part of the kingdom, and I think, therefore, that fruit growing, if taken up in earnest and properly managed, would certainly prove a success.

J. GROOM.

Gosport.

Easter Beurre Pear.—Your note in THE GARDEN (p. 115) on this Pear selling in Covent Garden for 2s. apiece wholesale is certainly a gleam of encouragement to fruit growers in this country, considering the low prices realised for most kinds of hardy fruits this last season. It is not stated whether they were foreign or home-grown fruit, but I would imagine that they must be foreign, and grand samples from the prices realised. Be that as it may, if home-grown fruit of fair sample could be sold for half or even a third that price, most growers would think themselves well paid. The planting of this variety deserves to be encouraged, for, as a rule, it is a sure cropper, and when properly ripened is most delicious, but why it got the name of Easter I cannot understand. For these last eleven years I may say we have never missed a crop, yet have never been able to have it at Easter, be it early or late, as it either ripened about the end of January or beginning of February, or not at all. This often occurs when the months of September and October are very wet and cold. Leaving the fruit on the trees as long as there is no danger of frost does not appear to have much effect on it. But I found in dull autumns when I had reason to fear they would not ripen well, that, by placing them in thin layers in boxes and taking them into a warm room, they ripened about the usual time: while some that were left in the fruit room were hard and green in May. This season Beurre Diep and Passe Colmar have not ripened at all satisfactorily, being deficient in flavour and tough; while, on the other hand, old Crassane and Vicar of Winkfield, only second-rate Pears at best and generally used for stewing, are this year first-class, and used as dessert.—W. WATSON, *Englehurst.*

SEASONABLE WORK AMONG FRUITS.

THE ground during the whole of the month of January having been ice and snow-bound, many operations in this department have fallen into arrears. Snow, however, is a fine protective agent as well as a good fertiliser, and when a long spell of severe weather passes away, as this has done, without a drop of rain, the ground invariably turns up in splendid condition for the performance of all spade work, be it ordinary digging or late planting. Although the first fall of snow caught us before we had quite completed the rearrangement of a few young fruit trees, the latter, snugly imbedded in snow, took no harm, and during the past week were finally disposed of and well mulched, but only loosely secured, as the ground, deeply trenched, will settle gradually for some time to come.

PRUNING AND NAILING,

especially of Morellos, which, Peaches excepted, we always leave till last, are now finished, and in order to protect them from the ravages of aphids the trees and walls are well washed with soap-suds, driven with some force through the garden engine. When this work is accomplished, the four-foot pathway receives about an inch of old, finely-broken lime rubble—a most excellent fertiliser for all stone fruit trees—and further care is dispensed with until the time arrives for thinning the fruit. From the north we turn to the south side of the same wall, where Peaches, usually detached early in January, were this year allowed to remain undisturbed until the frost broke up. These, made quite free from shred and nail, have received the final dressing over with the knife—a very pleasant operation—and every twig has been carefully washed over with strong soapy water. This operation, owing to the forward state of the

buds, has been performed with extra care, and the trees are worthy of it, as they are thickly clothed with blossom; the wood is brown and thoroughly ripe, and the prospect of fruit is extra promising. Many people commence the nailing or tying in as soon as the trees are washed, but this garden lying low and subject to spring frosts, I prefer keeping them away from the walls, which now begin to absorb sun heat, until the flowers show colour. Then, with all hands capable of laying in the shoots and wielding a hammer, this work is quickly performed. Meantime other matters require attention. One of these is the removal of all old mulching from the 4-foot pathway, which is forked into the vegetable part of the border. This is replaced by a good layer of old lime mortar, which serves as the first mulch and produces clean, dry standing ground for the workmen. Last, but not least important, comes the washing of the walls with the old brick-red paint, composed of quicklime, soot, Venetian red, a small quantity of linseed oil, and boiling water. Our walls being very old, and a fine breeding and hiding cover for all kinds of insects, this wash is thoroughly worked into the holes and crevices, and we rarely see aphid until after the fruit is set. Fruit growers in new gardens do not have these difficulties to contend with. Neither, on the other hand, have they the pleasure of circumventing enemies whose name is legion; and after all, success in all gardening matters is valuable in proportion to that which it costs. I have just said we can reckon on immunity from aphid until after the fruit is set—a small matter apparently, but really and truly the pivot on which success frequently hinges, for how often does it happen, especially in cold, wet seasons, that the poisoning of the early growths by greenfly results in a check upon the fruit and trees at a most critical period, when the second set of shoots owing to the delay are neither good nor properly ripened. Viewed from this point, a clean start is of vast importance, as we all know that badly ripened wood is the first step down hill; and the last, which speedily follows, is canker.

Autumn planted Strawberries.—These demand immediate attention. These, although firmly planted in cubes of new loam and well mulched with short manure, are more or less loose, and the ground has absorbed the contents of their larder. The surface just now is dry enough for scuffling, and a few weeds having started into growth, an unusual opportunity offers for hoeing, thorough treading, and top-dressing. Over-manning being hardly possible on ordinary soil, good spit manure is generally recommended, but our soil being very old and full of humus, rich discarded Vine border compost is used in preference. This is preceded by a good dressing of soot, and the compost, left rough often in ridges between the rows, is levelled down with a rake at leisure. Established plantations are treated precisely the same, but the old leaves are allowed to remain until the pushing of young growths renders trimming and dressing off necessary to the maintenance of neatness. It is yet early to make new plantations, but the ground may be turned over more than once to get it into first rate tilth, and when thoroughly dry it must be made as firm as an old pasture field, set out in squares to save time, and blocked with fresh, heavy loam ready for the reception of the young plants when they show signs of starting.

BUSH FRUITS.

Currants and Gooseberries are now arriving at a tempting stage and will require careful protection from the busy bills of feathered friends. Bullfinches with us, as in all wooded districts, are sometimes very troublesome; but instead of descending to the barbarous practice of spoiling the trees by shooting, we make their favourite food distasteful by syringing with a wash composed of finely-sifted quicklime and a few handfuls of soot and soap-suds. At one time I used to defer pruning until late in the spring, but finding this wash so thoroughly effective, all the bushes are now pruned in due course, and two syringings suffice for the season. Another advantage is free-

dom from Moss and Lichen; the wash is manurial and has a composing effect on the larvæ of caterpillars. Cuttings of approved varieties may still be put in, although autumn is the best time. Still, well ripened pieces of wood will strike freely in any ordinary soil and situation. Gooseberries, also Red and White Currants, should always be grown upon clean single stems, not less than 12 inches in height, and the better to insure freedom from underground suckers all the buds likely to be buried in the soil should be removed before the cuttings are planted. Those above ground assist in the formation of roots, but they must be pinched the first season and trimmed off the stems to the required height in the autumn. Black Currants do not require this attention, as they are more fertile and produce the finest fruit when allowed to stool and throw up many branches from beneath the surface. The mode of pruning also is different, all that is needed being a general thinning of the oldest and cross branches to let in light and air, and to encourage young growths from the base.

GRAFTING.

The time is now at hand for commencing this work, of which I should like to see more going on; and if orchardists in the west, like growers in Kent, would make themselves conspicuous by grubbing some of their old trees, nay, whole orchards, they might well afford to laugh at the ignorance of flying travellers who rush into the daily papers. If not already headed back, not a day should be lost in sawing off the branches to within a foot or so of the intended point of union, and scions must be transferred to cool, shady spots, where they will remain comparatively dormant until the sap flows freely in the stocks. Vigorous young trees in gardens may be grafted through the months of March and April; large orchard trees generally work and take best when operated upon in May. Ordinary whip-grafting is the most expeditious and effectual mode of managing young trees, and in order to prevent a check and produce numerous channels for the pent-up sap, a superabundance of scions may be put on and allowed to grow freely the first year. All spray, too, from dormant buds on the stocks may have free license throughout the summer, but they must be thinned out or shortened back where their presence interferes with the ripening of the grafts in the autumn. Trees so treated last year should now be trimmed out, superfluous grafts cut away for future stock, and those left, shortened back to form the foundation and proper balance of the future pyramid or bush. Amongst Apples a sharp eye should be directed to the union, as there, if anywhere, will woolly apbis be found. Whether present or not, it is a good plan to clear away the remains of all old ligatures and clay, then wash with a strong solution of Gishurst or paraffin, and re-daub with fresh clay and cow manure. Where scions have grown very strong and the newly formed matter is not considered powerful enough to hold them against high winds, a few stout sticks should be tightly lashed to the stocks to steady the grafts for another season.

FIGS.

Where these were well protected with dry Fern, and a rough coping board was provided for throwing off wet and snow, there exists but little doubt that the youngest points furnished with embryo fruits are now safe and sound. How to keep them so is the rub, as many people tell us that covering is a delusion and leads to mischief on removal; so is warm covering on early Vine borders, if, having taken leave of our senses, we suddenly remove our heat preservers and leave the stems or the roots of our trees to their fate. Prudent men do nothing of the kind, as this course would expose them to the charge of gross abuse; they therefore remove the covering bit by bit. Growers of outdoor Figs in the midlands and the north know very well that the pitcher may go safely to the well for years, but a severe winter overtakes the venturesome, and the

work of years is lost, for they have to cut their trees down to the ground and start again. In maritime counties, be they east or west, this rarely happens, although at highly favoured Arundel I once saw large standard centenarians which had been roughly handled by the ice king. Covering these was, of course, impracticable, but owners of well-trained trees against sheltering walls, far away from the salt spray cordon, can and will fall back upon dry Braeken, which they can draw out frond by frond as the Chinaman throws away his jackets. April is the time to commence, and I venture to say those who proceed with caution will never have occasion to regret the use of covering. When outdoor Figs are allowed to grow into a wild mass of branches 3 feet or more from the wall, it generally, I may say always, happens that the roots also are neglected, but this system can hardly be called culture, certainly not creditable or even profitable culture, as nine-tenths of the trees I have met with swell to a certain stage thousands of fruits which fall off during the winter, but unless the summer is exceptionally hot the most forward fail to ripen. Thin these trees, nail in the best shoots, allowing plenty of room for the sun to strike the wall when they are in full leaf, prune the roots, and give them poor soil to grow in. Mulch heavily and water copiously in summer, and they will do all that outdoor Figs in this country can be expected to do. They will set a good crop of embryo fruits every autumn, and they will swell them to maturity the following season, always provided they are well protected through severe winters. Open-air Figs rarely give a second crop of fruit in our most favourable counties; consequently the pinching of young shoots so often practised under glass is not only unnecessary, but injurious, as this mode of treatment would lead to the formation of young growths which our seasons are neither long enough nor hot enough to ripen.

Good and bad leaf-soil.—The quality of leaf-soil varies very much. Some sorts are well adapted for encouraging the production of roots and nourishing young plants, while other kinds are almost useless, the roots formed in them being few and weakly, and the progress of the plants unsatisfactory. Leaves collected under trees of a mixed character never make good leaf-soil; the best is obtained from an Oak or Beech plantation, both of which are generally to be found in all large places, and now that selling timber of all kinds has become so fashionable, I am surprised that those in charge of woods have never offered leaf-soil for sale. It is as valuable and scarce near towns as peat or silver sand, and if good samples of it were offered, the demand for it would doubtless be great. Leaves which are formed into hotbeds, with the addition of a little manure, are excellent for putting on Potato and other vegetable ground when their work as heat-producers has ceased. Pure leaves, such as those put into Pine-apple houses and pits, become useful for propagating purposes, and for mixing with the soil used in the early culture of young plants. The best of all leaf-soil, however, is that which has never been subjected to fermentation. This is produced without any effort, as the leaves which accumulate here and there in hollows and other places decay gradually without heating, and leaf-soil of this description is soft, sweet, and quite free from worms, fungus, or other impurities. Such material is excellent for propagating, and for using in potting composts of the best descriptions. All who use leaf-soil for potting should secure it of this description if possible. Some of the best leaf-soil we can get for ordinary purposes is obtained from a pond, the feeding stream of which passes through a large Beech and Oak wood. A good deal of sand which is mixed up with these leaves prevents them being carried away; they generally form ridges, which show themselves above the water. The pond is cleared out annually, and when the water has drained from them they become the best of leaf-soil. This material is excellent for Carrot soil or Asparagus beds, and we find it much better for propagating and similar work than the soil from the old fermented beds, which proves that

leaves reduced to mould by heating is the worst of all ways of preparing it.—CAMBRIAN.

GARDEN FLORA.

PLATE 584.

AMERICAN VIOLETS AND HARDY BUTTERWORTS.

(WITH COLOURED ILLUSTRATIONS OF VIOLA PEDATA AND PINGUICULA GRANDIFLORA.*)

ACCORDING to an American botanist, *Viola odorata* far excels all the American species in fragrance, and we therefore hear of its becoming naturalised in many places near dwellings in that country. *V. tricolor*, though now plentiful there, is not indigenous to America. Although *V. pedata* has no connection with the Pansy or *Viola* as represented in our gardens, there can be little doubt that if the same attention had been paid to *V. pedata*, *bicolor* and *sagittata* as has been paid to the improvement of *V. tricolor*, we would now be in possession of an elegant race of cut-foliaged Violets, perhaps not far behind those we now have for flower-garden decoration. In addition to the kinds here noticed in detail, there is a large number of species—something like thirty-two—besides thirteen varieties, all natives of North America, which do much to render our gardens interesting all through the summer months. Among others worthy of notice may be mentioned *V. blanda*, *chrysantha*, a really charming species, *delphinifolia*, *lancoolata*, *Nuttalli*, *primulifolia*, *pubescens*, *Selkinki*, *striata*, &c.; all of these do well with ordinary care on the rockery, the chief consideration being a comparatively moist soil in summer. Some may also be accommodated in the mixed border or flower bed. They are all propagated by division of the roots in winter, or from seeds, which should be sown as soon as they can be safely gathered.

The following are among the best:—

V. PALUSTRIS (the Marsh Violet).—This is a well-known plant, being found in many parts of Europe as well as in North America; it varies in size extremely, more especially in Southern Europe; we have had plants brought from Valais only about an inch in height, while others from the United States have been nearly a foot in height. It affects rather damp situations, and on that account makes an excellent addition to our rather limited number of dwarf bog plants. It has stolons, but they are short, and do not run so freely as those of many of the more robust kinds. It is a good plant for lining the low edges of artificial lakes, ponds, &c., where dwarf plants are required. It yields from April to July a profusion of largish lilac flowers, which in some of the forms vary to white. They are scentless, and have very short spurs; the leaves are smooth, nearly round, and cordate, with crenated margins. It is increased by division.

V. PEDATA (the Bird's-foot Violet) and the variety *bicolor* are undoubtedly the handsomest and most useful of all the American species. *V. pedata* is not by any means the earliest of Violets to bloom; some few species flower as early as March and the first week in April, while *V. pedata* is seldom seen in full beauty before the beginning of May. It, however, fully compensates for its lateness by its superior attractions, being the largest and showiest of all the native kinds. Not only are its flowers beautiful, but, as may be seen by the accompanying coloured plate, its leaves are delicately cut and Fern-like. *V. p. bicolor* seems to be the only distinct variety of it we have in gardens at the present time, with the exception of the white-flowered form, but I am told that in Pennsylvania alone its variations are very great, ranging from pure white to purple. These variations are, moreover, not always confined to the colours of the flowers, for the petals also undergo considerable modification. In some of the forms they are broad

* Drawn for THE GARDEN by the late Noel Humphreys in the York Nurseries, and printed by G. Sovereigns.

and round, while in others they are narrowed into mere floral stripes, detracting much from its value as a garden flower. *V. pedata* is perhaps best adapted for choice positions on the rockery, where it does well in peaty sandy soil, half shady, and not over-moist. It may also be grown well in pots for exhibition purposes. It may be increased by seeds and division. It was cultivated by Miller at Chelsea as early as 1759. (Syns., *V. digitata* and *flabellifolia*.) Bicolor, though always requiring careful management, may be grown with a fair amount of success in most localities. It is an extremely interesting plant, not unlike our garden Pansy, the colour variation being most pronounced in the two upper petals, which change to deep rich velvety purple or crimson, the lower ones varying to pale lilac or blue. Excessive moisture during winter seems to be what this variety most dislikes; therefore any little extra attention in guarding against this will be well bestowed. It

1 inch broad at flowering time, enlarging to 3 inches or 4 inches towards the end of the summer, and generally closely pressed to the ground. It is found from Maine to Michigan and along the Alleghanies.

V. cucullata (common blue Violet).—This species, which is very variable in habit, somewhat resembles our common Sweet Violet, but is devoid of the delicious scent that makes *V. odorata* such a general favourite with all lovers of hardy spring flowers. *V. cucullata*, as seen in cultivation, is much larger than *V. odorata*. Its leaves, which are all long-stalked and upright, are usually heart-shaped, and have a broad sinus at the base; they are sometimes variegated, and in this state make an interesting display in the rock garden. Its flowers vary also considerably both in size and colour; they are deep or pale violet blue or purple, sometimes nearly white or variegated with white. It is common on low grounds everywhere, and flowers from April to June.

V. cucullata.

likes a rich rather light peaty soil, and we find it does best on a western exposure. It is figured in the *Flora des Serres* as *V. p. var. atropurpurea*, t. 1361. It flowers in summer, and may be increased by seeds and division.

V. rotundifolia (Round-leaved Violet).—Though one of the old North American species, this has been until lately comparatively rare in gardens, and, as far as I can judge, it is an undoubted acquisition, even considering the large number of Violets now grown. It forms a short rhizome or creeping stem not unlike that of *glabella*. Being dwarf and compact in habit, it is very useful both for the rockery and front of the herbaceous border. The flowers, which are light yellow, are produced in great profusion during April and May. The leaves are round or heart-shaped, with slightly crenated margins; they are about

It merges into *palmata*, the leaves being from three to seven-parted. *V. cordata* is also a variety.

V. sagittata (Arrow-headed Violet).—This is said by American botanists to be an extremely variable species, *V. ovata* and *V. emarginata* being forms of it. One or two of its varieties are always the first to flower in spring, even before *V. cucullata*, which usually blossoms towards the latter end of March or early in April. It makes a charming addition to the rockery, where it never fails to produce an annual crop of sweet-scented flowers. In ordinary borders it also blooms with remarkable freedom. In borders, however, we usually raise the soil about it by means of stones, as it seems to prefer a rather dry situation. In the vicinity of Philadelphia I am told it is always found on dry slopes, and in this country it produces flowers more freely in well-drained beds. It is rarely

ever more than a few inches high, and it produces numerous rather large purple-blue flowers. Its leaves, which are oblong heart-shaped, half-bell-shaped, or arrow-headed, the latter form being the most prevalent, smooth, but often hairy, especially in the case of plants from high altitudes. It is fairly common in the Northern States in open fields and hill-sides, Canada, Michigan, and Florida; increased readily by division.

V. biflora (twin-flowered Violet).—This is really a charming little plant for half-neglected spots, &c. on rockwork. It is widely diffused over Europe and

V. biflora

Asia as well as America, and is now pretty well known in our gardens, where we find it particularly useful in filling up chinks in old walls and junctions of old steps, &c., in shady positions. We are told that in many parts of the Alps every crevice between the moist rocks is densely packed with it; its long roots and stems even crawl under great boulders, and it is frequently found lining shallow caves with its bright green kidney or heart-shaped leaves and bright yellow flowers. Perhaps the best clue to its treatment where conditions just named are not available, will be found in the fact that it grows intermixed with *Soldanellas*, and that where we find the latter do well, this Violet will also be found to flourish. Like *Arenaria balearica*, *Saxifraga Cymbalaria*, &c., there will be no difficulty with it when once fairly established, as it is well able to take care of itself. It is easily increased by division of the roots. The flowers, which are borne in pairs, are small, but bright, the lips streaked with black lines. They are produced throughout the summer months.

V. canadensis.—This is quite a different stamp of Violet from any of those enumerated in detail, having more or less of an arborescent look about it, although it dies down in autumn with the others. It is very easily accommodated in the ordinary flower border,

V. canadensis.

and is also useful in shady spots on rockwork, flowering, when well treated as regards compost, more or less from April until September. It grows from 1 foot to 2 feet in height, branching towards the top, and producing numerous whitish flowers, of medium size, and slightly tinged with purple underneath. The leaves, which are mostly on the stem, are heart-shaped, sharply pointed, and serrated at the margins.

It is found in moist woods along the Alleghanies. *V. striata* is nearly allied to it; it grows from 6 inches to 10 inches high, is branched, and bears numerous cream-coloured flowers, the lower petals of which are prettily streaked with purplish lines.

V. CLABELLA.—This pretty little species somewhat resembles *V. biflora*, inasmuch as the flowers are about the same size, and have the dark lines running from the eye, but it is only one-flowered instead of two, as in the case of the other. It forms thickish creeping rhizomes, which lie half-buried on the surface, and which are thickly covered with scales or leaf-scales. These rhizomes, when the plants are in robust health and any accident happens to the primary bud, produce buds which eventually throw up leaves and flowers on their own account. It is a charming plant for dry, sunny situations on the rocky, and grows freely in a light sandy soil, free in winter from stagnant moisture. It rarely grows more than a few inches in height.

BUTTERWORTS.

The *Pinguiculas*, or Butterworts as they are popularly called, are nearly allied to the Primworts, from which they differ among other points in having irregular flowers and also in the stamens being alternate with the segments. They are chiefly natives of temperate and cold regions, where they inhabit marshy places. Seven are natives of America; two, besides *P. grandiflora* and *lusitana*, are found wild in our own country in company with *Droseras*, &c. In the north of Scotland, and Ireland especially, they are pretty plentiful, one or two of the species being very abundant in Ross-shire, in many instances completely carpeting small tracts over the moors. The peaty ground in which they are found is naturally moist and spongy, and in cases of even prolonged drought the plants flourish and flower in quite a surprising way. In many places, however, in which they are plentiful, they are shaded by scraggy Heath. The treatment which they receive during winter in a wild state seems to be somewhat at variance with that which they receive under cultivation, the stations where they were most abundant being entirely under water at that season and impassable on foot. *Pinguiculas* are very interesting plants, and well worth cultivation where they can be accommodated. Their cultivation in pots is very simple, and I know of no sight more interesting than that of a well-flowered plant of the species figured in the accompanying plate.

In growing Butterworts out of doors it will be necessary to have a specially prepared bed for them, *ic.*, if there is no natural bog. It must not be too damp, and, above all things, it must be well drained. Peat to the depth of a foot or so must be provided, and a good sprinkle of Sphagnum, living if procurable, to keep them moist during the summer. If in a shady position, so much the better, as *Lycopodiums* may be introduced as well as *Droseras*, *Dionaea muscipula*, and other interesting alpine. During winter buds are formed in the same way as in the case of some of the Primulas; they are easily displaced, and birds in search of food often do a large amount of damage to them by stirring them up and leaving them exposed. The bed should never be cleaned or raked over in winter except with the greatest possible care. *P. grandiflora* (the Irish Butterwort) is, as may be seen by the accompanying plate, a handsome plant and one well adapted for cultivation in our gardens. It is apparently variable, even in a wild state, both in size and colour. It is found in Ireland, and is also abundant near Penzance, but is said to have been introduced. It is plentiful, however, in the west of France, on the Alps, Pyrenees, and other places, a rose-flowered one being found in the Alps of Dauphiny. For garden purposes *grandiflora* is perfectly distinct from *vulgaris*;

although often quoted as a sub-species, it is far more showy than *vulgaris*; indeed, few plants present a more charming appearance early in the year than a well-grown group of *P. grandiflora*; the mass of large, deep, and rich purple or rose-coloured flowers which it produces contrast well with the bright hue of the leaves. Next to *P. caudata*, a large, bright-coloured species, the Irish Butterwort is by far the showiest. *P. caudata* is not hardy in the open air; although it stood uninjured until well on into December, it succumbed at the first approach of severe frost; it is possible, however, with the protection of a hand-light to get through the winter safely. *P. vulgaris* is much smaller in every way than *P. grandiflora*, and useful only in the way of variety. *P. alpina*, a little white species with a yellow throat, is rare in cultivation. *P. lusitana*, which is also small, bears pretty lilac flowers, with a yellow throat; others worth growing are *lutea*, *villosa*, and *elatior*. D. K.

FERNS.

W. H. GOWER.

DORYOPTERIS.

THE charming small-growing Ferns belonging to this genus are nearly related to *Pteris*, from which they can readily be distinguished by their netted veins. The fronds of *Doryopteris* when mature are nearly all palmately or digitately lobed; in some instances, however, the immature fronds are quite different in form from those that are mature; they are thick and coriaceous in texture and deep green, whilst the continuous marginal band of brown sori is very conspicuous. These plants do not require a great amount of pot room, nor would they be so available for indoor decoration if they did. Although they enjoy tropical heat, the leathery nature of their fronds enables them to withstand with impunity a comparatively cool temperature, and consequently they may be used effectively in Wardian cases. This is the best time for repotting or surface-dressing them. If in Wardian cases, and the drainage is in good order, then a little fresh soil is all they require; in repotting care must be taken not to injure the roots; when that happens the fronds become deformed. For compost use a mixture of peat, loam, and sand. *D. nobilis* is a bold-growing kind—by far the largest species in the genus; when young the fronds are sagittate, but when mature, they become large, broad, and palmately divided, from 12 inches to 18 inches high, and about 9 inches broad; their colour is bright shining green, and in all stages of growth the divisions and segments are ornamented with a central band of white. *D. sagittifolia* is a free-growing plant with simple spear-shaped fronds, from 6 inches to 1 foot high, of a rich shining green. *D. aleyonis* is considered by some to be a miniature variety of the preceding; it is, however, we think, thoroughly distinct; for whilst in a small state the fronds are simple and spear-shaped, they ultimately become palmate, a change not seen in *sagittifolia*. *D. palmata* may be considered a miniature of *D. nobilis*, being much smaller in all its parts, the fronds seldom reaching more than 9 inches or 10 inches high. *D. pedata*, whilst resembling the preceding, is thinner in texture and more distinctly lobed. *D. collina*, again, is dwarfer and less divided than any of the other members of this genus.

SHORT NOTES—FERNS.

Fern album.—Having dried part of a collection of *A. Hartwegii*, *Pteris*, and *Schizandra*, I now wish to put them in some kind of album or book made specially for Ferns. Will some reader of THE GARDEN inform me where to get

such a book? or if not able to get one specially for Ferns, what kind of a book would be most suitable to put them in? —F. C.

Pteris Mayi.—This is a crested form of the well known *Pteris cretica albo-lineata*. It is very dwarf and compact in habit, and a plant that stands well in sitting-rooms.

TASSELLED AND CRESTED FERNS.

I OBSERVED some correspondence in THE GARDEN of August last on the subject as to whether the British Ferns are more prone to become tasselled and crested than the exotic species. Having had a little experience in collecting Ferns both in New Zealand and in the old country—say, about thirty years in New Zealand and nearly as long in Scotland and England—my experience may possibly be of some little service in the matter, as I observed that New Zealand Ferns are mentioned by at least one of your correspondents. In my experience I find more of the New Zealand Ferns than of the British have a tendency to become tasselled in their natural habitats. We have in one locality near Dunedin *Lomaria fluviatilis* so much crested and tasselled, that it would be difficult to find a plant that is not more or less tasselled at the ends of the fronds; and in other gullies in the immediate neighbourhood to all appearance as favourably situated, the difficulty would be to find a plant to sport at all of this the Fern most prone to do so of all our New Zealand Ferns. We have several very fine tasselled specimens of the *Lomaria* family, such as *L. discolor* and *L. alpina*, which, I understand, are both introduced into England. We have also a very fine tasselled variety of *Asplenium falcatum* and of *Aspidium aculeatum* var. *vestitum*, also of *Todea hymenophylloides*. And one of our small Tree Ferns, *Asplenium Colensoi*, is found with the pinnules all forked or branched near the midrib of the frond, which causes the pinnules to cross each other, giving the massive frond a fine appearance. Many others we have with forked or slightly crested fronds, but if left to Nature they soon disappear, as the normal forms soon choke them out if some of our hunters for those tasselled varieties do not find them and carry them off. A. C. PURDIE.

Otago University, Dunedin, N.Z.

The Parsley Fern (*Allosorus crispus*).—Two or three of the statements acent this pretty native Fern, as made at page 139, are, in my opinion, rather misleading. It is by no means easily cultivated, as every grower of our native Ferns knows right well, for you may imitate soil, position, and aspect, but you cannot introduce to your garden the pure mountain air in which this Fern above all others seems to delight. Instead of the broken bricks and peaty loam recommended for its culture, take my advice and substitute smashed-up slates freely commingled with a free, sandy, red loam, and nestle the plant away below some overhanging boulder where no raindrops can bedew its peevish crown, and you will succeed best—at least you will be imitating as nearly as possible its natural position and soil, minus, of course, the clear bracing air of its native hill-sides. If you cannot do this and must plant on the level, place a flat stone or piece of slate directly on top of the crown, for rarely, save in either of the above ways, or else projecting perpendicularly from an old stone dyke, do we see the Parsley Fern in its wildest luxuriance. You say it dislikes lime. That cannot be: for some of the finest tufts in that spot where it flourishes in greater plenty than in any other part of the British Isles—where the whole hill-sides and quarry faces are literally carpeted with it—are peeping out every here and there from the old Cambrian walls of stone and lime. It may not be partial to lime, but I question much if it dislikes it. Again, it is said that the Parsley Fern occurs in great plenty in a quarry in Perthshire; well, I have collected it in two of these, but it is not plentiful either in Ledriaskie or Ballindalloch slate quar-

ries; in fact, in Central Perthshire (Strathbearn district) it is considered quite a rarity. In Lediarskie quarry I only found one sizeable tuft, and I have visited this quarry on several occasions since that time, but the tufts of Parsley Fern were few indeed.—M. A. W.

KITCHEN GARDEN.

W. WILDSMITH.

VEGETABLES, OLD AND NEW.

THOUGH I do not class myself amongst those who accept for granted without inquiry all that is written, or all that certain persons may say for or against any particular variety of vegetable, I at the same time have at least as strong an objection to join the now fashionable class, namely, that which abuses all and sundry new introductions, apparently for no better reason than that they are new. I consider that the advancement made as regards novelties has been very great, and might have been greater had there been less rivalry amongst seed firms. Let us, for instance, take Potatoes. The best kinds a very few years ago consisted of Regent and Scotch Champion, which were excellent in quality, late in the season, but so ugly and deep-eyed that a lot of waste occurred in the dressing, and of time, too, in peeling. Now we have at least a dozen kinds of better quality, with a smoother surface, double yield, and less liable to the murrain. Amongst these are Magnum Bonum, Reading Hero, Prime Minister, M.P., Reading Russet, and others. As with Potatoes, so with Peas, not that the quality of such varieties as Ne Plus Ultra, British Queen, and Champion of England has been, or indeed is likely to be exceeded, but in robustness of growth that battles with drought and keeps mildew in check, a vast improvement has been effected by the introduction of such varieties as Telephone, Gladiator, President Garfield, and Duke of Albany; whilst as regards early varieties, we now get nearly as high quality as in the late Marrows in such varieties as William the First, Alpha, and Advance. To allude to the improvements made in other sections of vegetables would be but a reiteration of the foregoing, and as for obvious reasons the names of firms or introducers cannot be mentioned, I close by advising the sceptical to stick by their old favourites so long as they serve them well; but, at the same time, I exhort them to be charitable, and believe that improvement as regards varieties is possible, and not only that, but that it has already been accomplished.

SOWING SPRING ONIONS.

ONIONS may follow any crop that is cleared off early enough to permit of the land being trenched up before the winter is too far advanced. Manure should be liberally used, and if the land is light the chief dressing of manure should be given now in a well decomposed condition, night soil that has been worked up into a compost being specially effective. In manuring light soils for Onions it is best not to bury the manure too deeply. If lightly forked in, it will have more influence upon the crop than if buried deeply with the spade. The strength or essence of the manures being easily soluble in water, is in non-retentive soils carried deeply down with every spring shower, and though doubtless the roots follow and arrest some, still, I think, a loss has to be submitted to if the manure is laid too far from the surface.

THE MAGGOT is the great curse to the Onion crop on light soils, and in a dry season no certain remedy has yet been discovered. A dressing of salt, at the rate of 8 ozs. to the square yard, applied now will be useful. Nitrate of soda, at the rate of 6 or 7 lbs. to the rod or perch, may

also be recommended, not to kill the maggots or to prevent the flies from depositing their eggs on the plants, but the stimulating effect of the nitrate often enables the plants to make a rush past the period during which they are susceptible to the attacks of the maggot. Soot, again, is a most useful agent employed as a dressing now, and once or twice about the time the Onion fly is laying its eggs. A dusting of soot over the young plants, at the rate of half a bushel to the rod of land, about the end of April and again towards the middle of May will probably, by making the plants distasteful, cause the flies to lay their eggs elsewhere. Whenever the maggots do attack the plants all those infested should be removed and destroyed every two or three days, as, although it may not make the present crop any better, it will be the means of destroying large numbers of the insects, and so reduce the number of our enemies next year.

THE LAND MUST BE FIRM FOR ONIONS.—This is absolutely necessary to secure large, bright-skinned, well-matured bulbs with small necks, and this of course implies that the cultivating operations should be done during dry weather, even if we have to wait beyond the usual day for sowing, for it will never do to tread the soil when the surface is wet. If the land has been well worked and the surface made firm by treading or rolling, the drills should be drawn 10 inches apart and not more than half an inch deep. Onion seeds will grow if buried deeper, but thick necks and imperfectly formed and badly ripened bulbs are mainly caused by deep covering of the seeds. The latitude of the place should have some influence upon the time of sowing. In the south of London the earlier in March Onions are sown, if the land is in good condition, the better, but north of London from the middle to the end of March will furnish suitable opportunities for sowing. When we are quite sure that a large percentage of the seeds we are committing to the ground will grow, it is not wise to sow too thickly. It is perfectly true Onions can easily be thinned, but when sown thickly it is not an easy matter to draw those not required without disturbing too much those which are to be left for the crop. It is not necessary to grow many varieties; a true stock of the advanced type of White Spanish, such as the Sandy Prize or Nuneham Park, and a good type of the Globe, such as may be had in the Magnum Bonum, will supply every real need. E. HORDAY.

GLOBE ARTICHOKE AND THE FROST.

THOSE who neglected to protect the crowns of their plants either with rough strawy manure, or, better still, mounds of ashes, will in many cases find that the frosts have destroyed them. Even where they are so protected, considerable numbers are apparently either dead or so much weakened as to be rendered comparatively worthless. At any rate, I shall be surprised if half our stock of plants do us any good service this season without any extra trouble being taken with them. If they were of so little worth, as many seem to imagine, we need not concern ourselves about them; but as it happens the Globe Artichoke is considered a high-class vegetable in most large establishments, and not a few of the less wealthy classes have acquired a liking for it: consequently some method of renovating the plantations will have to be adopted. Luckily, it is no new experience, nor is there much room for regret, seeing that new plantations produce much the finest and most succulent, therefore the most valuable, heads. Many are content to depend on the old plantations till they are really obliged to renew them. So much superior in every respect are the young plantations, that we annually destroy two long rows and re-plant two others, none remaining undisturbed longer than three seasons. Globe Artichokes should be well grown, or not at all. Supposing a few strong clumps survive, they will soon push up a number of weakly leaves, and before these are far advanced the time has arrived for lifting and dividing. They may be split up roughly with forks or spades if necessary, every crown with a

portion of the old stem and roots attached being suitable for planting singly. In any case it will be late in the season before many of these arrive at a flowering stage, and in order to gain time I would advise that some of the old clumps be lifted and bedded in good soil somewhere in gentle heat, say an earlyinery. This will cause them to start quickly, and they may then be split up and potted off singly into 8 inch pots, or larger if need be. Any rich, loamy soil is suitable, and the plants should be kept in gentle heat till they have partially filled the pots with fresh roots, when they ought to be gradually hardened off preparatory to planting out. This may appear a laborious and uncalled-for proceeding, but it is no more than many of us find necessary in the case of Cannas and various other bedding plants. On no account ought Artichokes to be allowed to become badly root-bound, this causing premature flowering, and therefore the loss of so much labour. Planted out before they receive any check to their growth, they will, if properly attended to in dry weather, soon take to their fresh quarters and not be long before they are productive.

SEEDLING ARTICHOKEs are not often grown, this being partially due to the fact that no seedsman, at any rate that I have yet tried, is in a position to supply a good stock. A good percentage of the seedlings usually more closely resemble Cardoons than Artichokes, and, in all probability, the seed is saved in the neighbourhood of the former. These Cardoon-like Artichokes form strong branching flower-stems, and abundance of spiny worthless heads, which make us wish that good varieties were equally as prolific. Those seedlings, presumably of the Purple Globe variety, are the most uncertain, and if we find it necessary to sow any seed this season, the Green Globe only will be tried. Each time we previously grew seedlings we obtained several that produced extra fine distinct heads, and these were both succulent and good in quality. About half the plants were useless, the rest did good service at a time when Globe Artichokes were scarce. The seed may be sown in pans of fine soil, and placed in heat any time in March, the seedlings being potted off singly into 3-inch pots, and kept growing for a short time in gentle heat. Before they are root-bound they ought to be gradually hardened and finally planted out, some kind of protection being afforded when spring frosts prevail. These should produce heads early in July and last till September. Those who do not possess the facilities for raising plants early may yet rear plenty in the open ground. Early in April the seed should be sown, one long shallow drill perhaps being ample. The seed soon germinates. The seedlings require to be lightly thinned out at first, and eventually be left not less than 2 feet apart. If a second row of plants is required, some of the thinnings may safely be transplanted with a trowel. From seedlings raised in this manner we have cut very fine heads that were fit for use late in August and during September, or at a time when Globe Artichokes are not often seen in good condition.

PREPARING THE GROUND.—Artichokes, whether obtained by division of old stools or from seed, are gross-feeding subjects, and more than ordinary pains should be taken in preparing the soil for their reception. Where the nature of the sub-soil permits, bastard trenching should be resorted to, this, I may add for the benefit of the uninitiated, being the technical phrase for describing land dug two spits deep without reversing the positions. Plenty of rough manure ought to be mixed with the bottom spit, and a good dressing of partially rotten manure be well forked into the surface soil; the latter gives the plants a good start, and the roots find something to feed on when they reach the sub-soil. In the case of gravelly, chalky, or solid clay sub-soils, it is advisable to increase the depth of good surface soil by adding to it rather than resort to trenching, which is not always such an unmixed benefit as we are frequently led to believe. On light sandy soils we have prepared trenches as for Celery, and in these Artichokes grow most luxuriantly, especially if well supplied

with water during hot and dry weather. On well prepared land the rows of plants ought to be 3 feet apart, and ours are the same distance asunder in the rows. Starting early with single strong crowns, obtained by dividing the old clumps, these soon touch each other all round, and produce an extra strong branching flower-stem, and the plants last in a profitable state, as before stated, for two more seasons, always supposing they are not damaged by frosts. All vigorous old stools require to be freely thinned out both in the spring and autumn, otherwise a number of weakly crowns are formed, few of which are productive. Two or three strong growths only are requisite, these, if the roots have plenty of food and moisture about them, yielding abundantly. Last season we had a regular supply of good heads from June till late in November; and to prove, if proof be needed, how much Globe Artichokes are appreciated hereabouts, I should add that, out of the many hundreds of heads formed, not 10 per cent. were spoilt. Both these and Cardoons are of an ornamental character, and when planted in thin or newly-formed shrubberies and other positions in the pleasure grounds they are as effective as the majority of sub-tropical plants. The soil in which they are planted ought to be well enriched, otherwise not much progress will be made.

W. I.

MUSHROOMS FAILING.

I FIND many fail to get Mushrooms to grow satisfactorily, although professional gardeners contrive to grow them in all sorts of places, and even to get a continuous supply from open-air beds; and although we find Mushrooms springing up spontaneously, yet if we want a supply at a given date there is hardly a crop that comes under the gardener's care that needs more attention. The following are a few failures I have lately traced as being clearly due to want of the commonest precautions, viz. :—

Too shallow beds.—A gentleman who has been trying in vain to get Mushrooms to grow lately called on me, and said he had made his bed up exactly as described in treatises on their culture, but that no Mushrooms appeared. On inquiry, I found his beds had only 9 inches thick of manure, consequently it was impossible for the heat to be retained long enough to be of any service in the winter time, and had it been in the months when Mushrooms grow out of doors, there is little doubt that he would have been successful, but to put spawn into beds less than 1 foot thick is to court failure.

Too cold quarters may also be credited with plenty of failures during the winter. I lately went to look at some beds that the owner had taken great pains with, but as the Mushrooms did not appear he concluded that the spawn was bad. The reason, however, was obvious. The roof was made of corrugated iron, and the wind was driving in at every crevice, so that the beds were chilled worse than if in the open air. The owner said he had read of Mushrooms being grown in unheated sheds in winter. I have grown them myself in unheated places, properly speaking, but they have been close and warm, either by means of thick thatch or ceiling, or else in underground cellars, and in such places where beds are being constantly renewed the fermenting material will keep the temperature from ever falling below 60°. Many other causes might be cited, but the above are samples that frequently occur. Without going minutely into details, it must be obvious to anyone who observes the weather we get when Mushrooms are springing up on our pastures, that unless we give them treatment somewhat analogous as to moisture, temperature, &c., we shall look in vain for a crop. It is only as long as the latent summer heat lasts, and especially after droughts, when the soil is moistened by copious rains, and the nights are still and the Grass dripping with dew, that we get Mushrooms to spring up as if by magic. We cannot exactly fulfil these conditions, but we must copy Nature as near as we can, or failure must follow.

J. G. H.

Broccoli is generally good up to Christmas, but from then onwards to the beginning of March

such is unfortunately not the case. The fact is, that it is next to impossible to obtain Snow's true, and we have no good Broccoli to fill the gap between Veitch's Autumn, Leamington and Sprouting Broccoli. In succession to these come Cattell's Eclipse, Carter's Summer, and Veitch's Model, and these carry us on till the earliest Cauliflowers come in. These late kinds come into use at a time when vegetables are scarce. Nor do they make unprofitable crops for marketing, coming in as they do before the Cornish Cauliflowers, Ledsham's Latest of All, though very fine, is, I fear, rather tender.—J. R.

KITCHEN GARDEN NOTES.

CELERY.—It is now time to make the first sowing in pans to be raised in frames in which there is a temperature of about 60°, and if a second sowing be made a month hence there will be no occasion to sow again, as by pricking out the largest seedlings from these two sowings at various times a regular supply of the right sized plants may be had as ground becomes vacant on which to plant them permanently. I know of no vegetable that is more susceptible of failure from premature seeding or, as it is technically expressed by gardeners, "bolting." But this defect being solely the result of neglect in the earliest stages of growth, the remedy is obvious, namely, to be cautious that throughout the earlier stages of growth a check of any kind is occasioned to the plants, such as results from overcrowding in the seed-pans, a too sudden change from warmth to a colder temperature, lack of water, or by transplanting being done carelessly, with little or no soil adhering to the plants, and neglect to water them till well established in growth. When once that stage has been reached without the occurrence of any one of the causes of failure enumerated happening, a long continued drought, or the advent of the Celery fly, will find plants in such robust vigour as to effectually baffle their power to injure. Of course, if time can be afforded to mulch and water during prolonged drought, the produce will be proportionately larger and of better quality, and even if the fly does put in an appearance, an effectual exterminator will be found in dustings of soot, or wood ashes, or of both in mixture, applied in the early morning whilst the dew is strong, that the materials may adhere to the plants. I have occasionally met with amateur gardeners that do not grow Celery, owing to the prevalent idea that it can only be grown by applying manure in prodigious quantity, and though there can be no doubt that too much of this commodity is preferable to having too little, circumstances have many times compelled me to use so small a quantity, as with perfect truth to call it a mere apology for manuring, and yet our first scoring of failure to have moderately good produce has yet to be recorded. Given deep cultivation with free admixture of the refuse vegetable mould and ash from burnings of scraps from the clearings of hedges and ditches, and good produce may be had without a particle of manure being put in the rows or trenches. The best manure for this vegetable is old Mushroom-bed dung and rotted cow manure well mixed together; this should be spread in the trenches about 4 inches in depth and then deeply dug in with long steel forks. We prefer to plant in double rows, the width of the trenches being 30 inches, and the plants put in angularwise at a foot apart. If planted with good balls of earth attached, the watering they should receive as soon as planted ought to suffice till they are well established, when, should the weather be dry, watering would be advantageous, but if impracticable, apply all over the trenches about 3 inches depth of droppings or fine soil, which will keep the roots at work till rain comes, by preventing the too rapid evaporation of moisture.

Earthing up.—Only in respect of a small quantity that may be required for very early use, before the general lot is well blanched do we earth up, till the plants have nearly or quite completed their growth. To do this sooner is labour worse

than wasted, as, in the first place, the soil gets into the hearts of the plants, the great depth of soil militates against heat, air, and moisture, having due effect on the plants; and lastly, there is really no occasion for expending the great labour a half a dozen earthings involve, when, by one only, the blanching is just as perfect in a month's time from the process being done as it is in the case of plants that were earthed up three months earlier. Varieties are too numerous; those that I prefer are Dwarf Incomparable, synonymous with Sandringham, Sulham Prize Pink, and Major Clarke's Red.

TOMATOES.—The demand for these grows, and being used in so many different ways, one begins to feel some amount of hesitancy as to whether to class them as fruit, salad or vegetable, for really and truly they are all three in one; but the balance of preponderance being, as I think, on the vegetable and salad sides, I claim allusion to them in this department of the paper. Our first sowing we have just potted singly into 5-inch pots, and placed on shelves in an earlyinery. This batch is intended to be fruited in pots, and they will be grown on as rapidly as is consistent with the securing of sturdy, short-jointed stems. Each plant will be allowed to have but one main stem, and suckers springing from the base of it will be persistently pinched off; on the side or lateral shoots the fruit is formed, and soon as it is set and about the size of large Peas, the points of the shoots will be pinched out, and as further growth is made repeated pinchings will be continued till the fruit is ready to gather. This constant repression of wood growth materially aids the early ripening of fruit, but it is, of course, at some expense of size of single fruit as well as loss in bulk of general crop, but to get a few dishes extra early it is worth while to make some amount of sacrifice. Later plants that are required for succession will be grown on more leisurely, and will have but a small amount of pinching; the object being to obtain the largest amount of good sized fruit, there must of necessity, therefore, be more shoots, and as this batch will also be allowed to fruit in pots, what I call a natural process of repression of growth will begin the moment the pots get full of roots. We shall make the last sowing for the present season forthwith, and from this sowing shall select a last batch for indoors fruiting in pots immediately previous to obtaining supplies from the open air, but the bulk of the seedlings now to be raised will be grown on in pots with a view of having extra strong plants fit for open-air planting early in May. Later sowings may do in favourable seasons, but the odds are in the other direction, and I would therefore advise immediate sowing.

PLANTING ONIONS FOR SEED.—No reflection is intended or implied on any seed firm, or on the trade in general, when I say that, as a rule, the best seeds are those saved by the cultivator himself. The reason is obvious: there is constant personal supervision, and on pet objects no pains are spared to keep the stock true. Still, I would not be understood as advocating that everyone should be his own seedsman in everything, for were that to happen a very few years would suffice to land us in a fine muddle of mongrel stocks, occasioned by one neighbour going in for saving Cauliflower seed, and another neighbour's bees and the wind together would carry the pollen from his seeding Cabbage, and thus the round would continue. It is, however, a very different matter to grow only one or a couple of favourite stocks of seed for one's own use, and my hobby in this direction for a considerable period has been Onions, and out of it I manage to extract a large amount of pleasure and some profit (not cash, but learning), and the principal lesson has been demonstrative proof that by regular selection of the most perfect types for seeding is, if not the royal road to perfection, very nearly in that direction. Our bulbs have just been sorted ready for planting as soon as the weather will admit of our doing it. They fully appreciate a well-drained and deep, rich soil, and a position with full exposure

to the sunshine. We plant a foot apart each way, and, the bulbs being large, we make holes with a trowel, and well press the sets up to the base of the stems in the soil, and till well rooted they are, after each recurrence of sharp frost, again well firmed in the soil. We used to be troubled with the bulbs rotting off after the first flush of growth, notwithstanding all our care to plant only such as were perfectly sound, and for several seasons, the affection not being serious, took no heed of the matter. But at length the awakening came by the collapse of more than the ordinary number, which on examination were found to have made new roots, but which were in process of being eaten up wholesale by the ordinary Onion maggot. This attack of voraciousness had due effect on our memory the following season when preparing the ground, as to cause us to apply an antidote in the shape of a somewhat free use of soot and lime, the end of the matter being that the maggots' loss was our gain, both as regards peace of mind and seeds.

CUCUMBERS.—For growing in pits during the summer our plants are new in rough leaf, and the fermenting material for bottom-heat is in course of preparation, and consists of two-thirds leaves and the other of stable litter. We hope to make up the beds within the next few days, when the compost—light fibrous loam only—will be put on at once in hilloek fashion, and of sufficient width to admit of putting out two plants to each light, and additional soil will be added as soon as the roots are seen on the surface, and, meanwhile, the surface of beds not soiled will be of the greatest service, aiding as it will our scant supply of hot-water piping to maintain a temperature of 65°, which, except on very cold nights, will be the minimum temperature aimed at. Nightly coverings of mats, or some such material, is essential all through the spring months, and is better for the plants, even if the weather be sufficiently mild to do without it. We prefer to dispense with the fire-heat. Our favourite varieties for frame culture are Telegraph, Master's Prolific, and Cluster.

GENERAL WORK.—Marking out and labelling the various plots for seed-sowing as soon as weather conditions are favourable. Digging and manuring the borders recently occupied with Autumn-protecting Broccoli, Endive, Lettuce, and Parsley, part of which ground is immediately required for planting out Garlic, Shallots, sowing Radish, and a first small patch of Turnip. When the ground is hard through frost, manure and soil-wheeling is pushed forward; the latter material has been applied with a free hand over Raspberry and bush-fruit plots, which we never dig; indeed, the ground is such a complete network of roots that digging could not be done without serious damage to the bushes. The same remark applies to Asparagus plots, the top-dressing of which we have just done; also the lifting of remainder of Parsnip crop. W. W.

SHORT NOTE.—KITCHEN.

Chou de Burghley—I have grown this every season since its introduction, and I must reluctantly own that it has greatly disappointed me. The flavour is perhaps all right, although I think it inferior to that of good sprouting Broccoli, but the appearance of a quarter of it, looking as it does like a very inferior strain of Sugar-loaf Cabbage, is not at all creditable in a well-kept garden or select vegetables.—J. R.

Decorative purposes.—Those who use this expression somewhat freely may be glad to know that it originated with the floral committee of the Royal Horticultural Society. Some few years ago the committee, when confronted with plants in flower which could hardly be judged by florists' standards, and yet were so beautiful and so useful for all ordinary purposes, that, fearing to encounter an outbreak of criticism from the florists, compromised the matter by terming them decorative plants or kinds; hence the introduction of a descriptive term which means anything or nothing. Perhaps the term "decorative" has obtained some additional force by being applied to certain kinds of plants used in dressing houses, windows,

halls, and similar places. Some plant groups are also termed decorative groups.—A. D.
